Cheltenham.—The Town Council have decided to approve of the principle of the proposed extensions of the light railway to Charlton Kings and Leckhampton, provided satisfactory terms are arranged between the Corporation and the company. On the other hand, the Chamber of Commerce have passed a resolution that, while agreeing with the general extension of the Cheltenham and district light railway, the Chamber is of opinion that the proposed route through High-street would be impracticable.

Post Office Motorvan.—On the 1st inst. the first motor postal van in the service of the Government left Liverpool for Manchester. This new service supersedes the horse vans which have previously carried the parcels between the two towns. The car weighs just under two tons, and can carry a load of 30cwt., as against a load of 18cwt. borne by the old vehicles. The distance between Liverpool and Manchester is 38 miles, and the motorvans are schedule to maintain a maximum speed of eight miles an hour on the journey.

Salford.—The electric cars have now superseded horse traction on the Lower Broughton tramway, and the last of the horse cars has been seen at Victoria Bridge. The ordinary service is to be one of 7½ minutes, while at the busy periods of the day additional cars will be run. To-day a similar service will be inaugurated on the length from the sanatorium at Weaste to Eccles Cross. From May 2, 1901, to March 31 last, the end of the financial year, the Corporation carried 20,935,000 passengers on their tramways, the mileage being 2,100,000.

Weston-super-Mare.—Monday afternoon last saw the formal inauguration of the electric tramways at this place. Under present arrangements the cars will run every 10 minutes from 8 a.m. until 10.20 p.m., but as the season progresses these times will be subject to revision. At present the fares are 2d. for any distance travelled, but this, of course, is also subject to revision. No stopping points for picking up passengers have yet been decided on, and the hailing method at any point, for the time, will be observed. Each car accommodates 50 passengers.

Bury.—An agreement has been signed under which the Johnson-Lundell Company will lay down an experimental line on their surface-contact system in Rochdale-road, and a deputation from the Town Council are to visit Wolverhampton for the purpose of obtaining all information possible with regard to the new tramway system in that borough, and then report. The borough engineer in the meantime has been instructed to prepare specifications and drawings for laying the permanent way of the Fairfield, Bolton-road, Knowsley-street, Clough-street, and Heywood-street sections.

Darlaston.—It seems that the construction of the proposed new tramway between Darlaston and Morley is being delayed owing to the obstructive attitude which the Wednesbury Corporation have taken up. A short length of the tramway would be within the Wednesbury boundaries, and owing to a hitch between the British Electric Traction Company and the Corporation the work cannot at present be proceeded

Digitized by Google

with. The Darlaston District Council, however, are in communication with the Wednesbury Corporation, and the company have stated that they hope very shortly to commence the construction of the tramway.

Loughborough.—The Light Railway Syndicate have intimated to the Town Council that promising negotiations are in train for the financing of the scheme for the supply of electricity and the establishment of the light railways, but as the arrangements are not complete the syndicate cannot take the risk of giving a definite undertaking. In the circumstances the Town Council have decided to interview the Board of Trade, and laying the special circumstances of the case before that authority with a view to getting a further extension of the time limit fixed by the Corporation Act of 1899 within which the electrical powers of the Corporation were to be taken up.

Cardiff.—The electric tramways were formally inaugurated on the 1st inst., when a service of electric cars was put on three of the reconstructed routes. Notice of motion has been given to be brought forward at the next meeting of the Town Council in favour of running the electric cars on Sundays. The Corporation have received a proposal from the Glamorgan County Council to confer with them as to the desirability of a joint promotion of tramways or light railways of the nature of tramways upon roads leading out of the borough into the county district, or, if thought advisable, on new routes. The matter has been referred to the Tramways Committee for consideration.

Blackpool.—The Tramways Committee's report presented at the last meeting of the Corporation showed that on the Promenade and Lytham-road tramways the receipts for the year ended March were £32,600, and on the Marton route £9,225, a total of £41,817. The total expenditure was £28,259, leaving a gross profit of £13,558. This was to be dealt with as follows: £6,648 interest on capital and sinking fund; £1,706 as the third instalment of doubling the line on the Promenade from Hounds-hill to Cocker-street; and a further expenditure of £1,723 for loans, etc. This left £3,479 to go the rates. There had been no fatal accident on the tramways during the past year.

Macclesfield.—A special meeting of the Town Council was held last week to consider an offer from a syndicate to lease the electric lighting from the Corporation and to construct electric tramways in the town. The scheme is a large one, including connections to other towns within the influence of Macclesfield, and involves an estimated expenditure of £500,000. As the result of a long discussion, it was decided to favour the introduction of trams into the borough and to appoint a sub-committee to deal with the matter. It may be mentioned that during the debate it was stated that the engineer (Mr. Godfrey Evans) advised that the electric lighting and tramway scheme should be combined.

Haslemere-Farnham Tramway.—It is suggested in the *Farnham, Hindhead, and Haslemere Herald* that an electric tramway without rails, or pneumatic-tyred motor-omnibuses guided and impelled by aerial electric cable, such as is being installed between the various villages on the borders of the Lake of Lucerne, should be constructed between Haslemere and Farnham, connecting Shotter Mill, Grayshott, Hindhead, Headley, and Frensham. This new mode of communication, which was fully described recently in this journal, does not involve nearly the outlay incurred for an ordinary electric tramway, but the question as to its adaptability to the country roads of England remains in considerable doubt.

Blackburn.—In connection with the loss of £6,000 or £6,500 on last year's working of the trams, the question was asked at the last Town Council meeting as to what amount, if any, was included in this item for depreciation of rolling-stock, tramrails, and the whole tramway equipment; or did this £6,000 or £6,500 represent actual working loss, apart from depreciation of rolling-stock, etc.? The Borough Treasurer pointed out that this was the first year that the tramways undertaking had been working at its full capital, and the necessity had not arisen to form a depreciation fund further than that provided for in the sinking fund, but in future years no doubt the need for such depreciation fund would arise.

Tottenham Court-road Tramways.—It will be remembered, with reference to the Tottenham Court-road tramways, that the London County Council had a clause in their General Powers Bill asking for power to lay tramways down Tottenham Court-road. That clause had to be dropped as the Standing Orders of the House of Commons had not been complied with by obtaining the consent of the St. Pancras Borough Council as the statutory road authority. The County Council now propose to introduce a clause in committee of the House of Commons endeavouring to coerce the Borough Council of St. Pancras into giving its consent by refusing to go on with the Hampstead-road widening unless such consent is given.

Douglas.—The Corporation have entered into an agreement with the Isle of Man Harbour Commissioners for an extension of the Bay Tramway on the Victoria Pier. This will be a great convenience to visitors, as it shortens the distance from the boat to the trams by 200 yards. The Clerk of the Rolls, sitting in Chambers at Douglas on Wednesday, granted the application of Mr. Ernest Schenk, of 20, Queen Victoria-street, and Crystal Palace, London, for an extension of time to complete the purchase of the electric tramway undertaking of the Isle of Man Tramways, Limited, to 31st inst. The purchase price is £252,000, and comprises the line from Douglas to Ramsey, and the line from Laxey to the summit of Snaefell, together with stations, plant, and rolling stock.

Birmingham.—The City Council on Tuesday adopted the recommendation of the Tramways Committee, that power should be obtained for the construction of a double line of tramway, two furlongs three chains in length, commencing at the junction of the existing tramways in Aston-street with those in Lancaster-street, and proceeding thence along Steelhouse-lane, and terminating in the last-named thoroughfare, near its junction with Bull-street; and for the equipment of the tramways now leased to the Birmingham and Aston Tramways Company within the city on the overhead electric trolley system. The Council also approved the inclusion of clauses submitted by the Tramways Committee in the General Powers Bill. It was explained that except for the omission of the Edgbaston and Harborne tramway scheme and the inclusion of the Steelhouse-lane route, the clauses were the same as were applied for last year.

Aberdeen.—On Monday the electric cars to the bathing station commenced running regularly. Much satisfaction has been expressed in the town with the decision of the tramways authorities to continue the double line in King-street to Merkland-road, instead of stopping at the City Auction Mart, as was at first intended, since a very large source of traffic can be tapped at Merkland-road. Rapid progress is being made with the work on the King-street route. Notice of motion before the Town Council has been given that "in connection with the report of the Finance Committee regarding the Aberdeen Suburban Tramway Provisional Order, the Council desires to express its strong dissatisfaction with the arrangement made by the Secretary for Scotland to hold the enquiry in Edinburgh, and that, in the opinion of the Council, the action of the Secretary for Scotland is contrary to the spirit of the Private Bill Procedure Act and against the public interest."

Shields and Sunderland Tramways.—The Duke of Northumberland's Committee of the House of Lords commenced consideration of the South Shields, Sunderland, and District Tramways Bill on Tuesday. Mr. Balfour Browne explained that the Bill would authorise the British Electric Traction Company to construct tramways between South Shields and Sunderland. The lines would start at a point in the northern part of South Shields, and would pass through Harton to Whitburn. There one branch would turn to the east for some distance and then go south to Sunderland, while the main line would proceed due south direct to Sunderland. In each case the lines would join the authorised lines in the hands of the Corporation of Sunderland. The length of the lines proposed to be constructed was eight miles one furlong. They would be constructed upon a 4ft. 8½in. gauge, and would be worked by electricity on the overhead trolley system. The parishes through which the lines would pass were supporting the scheme, and only the South Shields Corporation opposed it.

Manchester.—The financial year just closed has been a successful one for the tramways undertaking of the Corporation, and at a meeting of the committee on Wednesday it was decided to hand over £30,000 of the past year's profits for the relief of the rates. This is £10,000 more than the amount paid into the city fund last April. With regard to the purchase by the Corporation of the plant and properties of the Manchester Tramways and Carriage Company, Sir Frederick Bramwell has now issued his award, offering two alternatives. The arbitrator leaves it to the Law Courts to decide whether the purchase shall be limited to the plant that the Corporation actually require, or whether the Corporation shall buy the whole. He finds in favour of the company that the Corporation should buy the depôts, rolling stock, and horses for the whole system, and on this basis awards the company £496,068. If, on the other hand, the Courts decide that only such stock as is required by the Corporation shall be purchased, he reduces this sum to £229,353. Sir Frederick Bramwell himself is in favour of the purchase by the Corporation of the whole of the plant.

Singapore.—As we announced a week or two ago, it is proposed to lay down a system of electric tramways in the Settlement of Singapore. We now see from the Straits Settlement *Government Gazette* of March 27 last that an ordinance has been issued by the Governor of the colony authorising the scheme. The *Gazette* containing the ordinance, which gives detailed particulars of the requirements as regards construction, motive power, by-laws, fares, rates for supply of electric energy, etc., may be seen on application at the Commercial Intelligence Branch of the Board of Trade, 50, Parliament-street, London, S.W., any day between the hours of 10 a.m. and 5 p.m. In Article 79 of the provisions of the ordinance it is provided that all engines, boilers, electrical generating apparatus, and power station equipment, car bodies, and electrical equipment therefor, including motors, shall be of British manufacture; and the Governor in Council may, in case the same or any of them shall not be of British manufacture, forfeit the same, and for this purpose remove the same and dispose thereof as he may think fit for the benefit of the Government.

North Metropolitan Tramways Bill.—This Bill, the preamble of which was passed last week, was further considered on Thursday by the Select Committee of the House of Commons presided over by Mr. H. Hobhouse in regard to clauses. Mr. Wheeler, K.C., submitted a proposal which would enable the local authority of Wood Green, which had obtained from the Board of Trade a provisional order empowering it to supply electrical energy, to provide the electric current for the tramways. The provisional order, he could assure the committee, was not a bogus one, and it was hoped that in due course it would be confirmed by Parliament. The Chairman said the Middlesex County Council, which was the road authority, intended to work its tramways in connection with the North Metropolitan Company, and would, therefore, use electricity. In these circumstances the committee could not agree to bring in another company with a veto as to the supply of electricity. If Wood Green desired to have this power, it should appear in the House of Lords when the Bill reached there, and ask for it. The clauses having been adjusted, the Bill was ordered to be reported for third reading.

Nottingham.—The Tramways Committee report that the property required for the widening of Upper Parliament-street, at the Derby-road end, has been purchased, and the old buildings thereon have all been pulled down and cleared away. The Council already possess parliamentary powers to construct a section of the tramways from the junction of Upper Parliament-street with Derby-road, along Upper Parliament-street to the bottom of Market-street, and the committee are of opinion that the lines should now be laid as far as the widened

Digitized by Google

portion of the street extends, and they recommend the Council to authorise them to have this short length of the tramlines laid before the paving is done. The committee do not propose to construct the tramways along the remainder of Upper Parliament-street and down Market-street until the powers now being sought in the Bill in the present session of Parliament for making a communication between the Market-street tramlines and the existing tram system in the Great Market-place have been obtained. The official inspection of the Woodborough-road section of the Corporation tramways was made on Tuesday afternoon by Major J. W. Pringle, R.E., the inspector appointed by the Board of Trade, who expressed entire satisfaction with the route, and gave sanction for the cars to be run for public use immediately.

Light Railway Competition.—At the Board of Trade on Monday Sir Herbert Jekyll heard an objection by the London and South-Western Railway Company against the confirmation of the Poole and district light railway order, which raised the important question of whether light railways competing with existing railway companies shall go before the Light Railway Commissioners or before Parliament itself. Mr. Page, K.C., for the South-Western Railway Company, argued that where an existing railway company would be seriously injured by a light railway or tramway the scheme must go before Parliament, and could not be sanctioned by the Light Railway Commissioners or the Board of Trade. The railway companies all over the country had allowed these light railways to be promoted without opposition, and they were only beginning to find out what formidable competitors they might become in the future. There seemed no reason why, by a series of extensions, these light railways should not go parallel to the existing big companies all over the country. But Parliament, when it originally gave powers to the existing railway companies, did so on the distinct understanding that no rival schemes should be promoted without coming before Parliament for sanction. If it were otherwise, then the qualified monopoly obtained at great cost to the railway companies would be done away with, and the railway shareholders would be sufferers. Mr. Morse, for the promoters, submitted that Parliament had delegated the sanction of light railways to the Light Railway Commissioners and the Board of Trade, and they were to decide what was best for the public convenience. Sir Herbert Jekyll said the Board of Trade would consider the question and communicate their decision.

Embankment Tramways.—The Select Committee of the House of Commons of which Mr. H. Hobhouse is chairman have this week been engaged in considering the proposals embodied in the London County Council Tramways and Improvements Bill, one of which is for a tramway along the Victoria-embankment from Westminster Bridge to Blackfriars Bridge. There were 10 petitions against the Bill. Mr. Pollock, K.C., on behalf of the promoters, explained that there were altogether about 115 miles of tramways within the jurisdiction of the London Council, 74 miles were already under the control of the London County Council, 15 or 16 miles would soon come into its hands, and the County Council intended to take over the remaining 25 miles as soon as the licenses to the present owners had expired. It was expected that by the year 1910 the whole of the tramways in London would be under the control of the London County Council. The first new line the Council proposed would be one four miles in length from King-street, Hammersmith, to Putney Bridge, by way of Fulham Palace-road. The second would be along the Victoria-embankment from Westminster to Blackfriars. The minimum breadth of the Embankment, he pointed out, was 64ft., and the rails of the tramways would occupy only 13ft. The third proposed tramway was from Plumstead-road to Eltham, and the fourth from Camberwell Green by way of Grove-lane to the Crystal Palace tramway. These tramways would connect the other systems of the London County Council tramways, and would be worked on the underground electrical conduit system. Mr. Baker, vice-chairman of the County Council Tramways Committee, gave evidence on the Embankment tramways, and denied that it would be a disfigurement to the Embankment, as the conduit system would be adopted. The Council hoped to make the Embankment a means of taking through traffic from the north to the south. Ultimately, no doubt, the tramways would be carried over Westminster Bridge. Mr. John Burns, M.P., said he came before the committee in the interests of Battersea working men to give evidence in support of the Bill. His view was that the tramway ought to be taken over Westminster Bridge. He did not think the construction of the proposed subway down the new avenue to the Embankment ought to take more than 18 months, and did not agree that it was better to wait till that was constructed, and then come with the complete scheme. Asked whether the proposed tubes would not help Battersea working-men, Mr. Burns said the people in his district would rather travel at eight miles an hour on an electric tramway on the surface than at 14 miles an hour underground. The committee adjourned.

Middlesex Tramways.—The Bill promoted by the Middlesex County Council for providing tramway facilities in the county came before the Select Committee of the House of Lords of which the Duke of Northumberland is chairman. Lord R. Cecil, K.C., said the general nature of the proposals was that the County Council should in certain circumstances and with certain safeguards be allowed to purchase tramways in their county by agreement with local authorities. The great justification for the Bill was the peculiar geographical position of Middlesex. Throughout the county population was rapidly increasing; in 1891 it was 343,000, in 1901 it was 800,000. With this large and rapidly increasing population affected by London in various ways the existing railway accommodation was insufficient, and there had been enormous extensions of light railways and tramways passing through the district of various local authorities. The object of the Middlesex County Council was to be admitted as the general local authority within their county, and the Bill provided that the powers of purchase conveyed by the Act of 1870 should be exercised by the Middlesex Council with the consent of the local authority. It was in no way sought to vary the terms under which a tramway had been constructed, and he questioned the right of the United Tramway Company to appear against the Bill. Sir A. Binnie, C.E., gave evidence from his experience with the London County Council as engineer in connection with communication along main roads. He was in favour of the proposal in the Bill, which, if granted, would obviate the necessity for negotiating with many local authorities for securing unity of control over tramways. At the same time the Bill would in no way prejudice the rights of local authorities, inasmuch as the powers, if granted, would only be exercised by agreement. He hoped that at no distant date the tramway systems of London and Middlesex would be linked into through communication. Opposition was offered by the London United Tramways Company and several of the local authorities, but the chairman said the committee found the preamble of the Bill proved. There were, however, certain points they wished made quite clear. It had been urged that under the Act if the county council were by agreement to buy a tramway the district council could, at the expiration of a term of years, repurchase from the county council. If there was any doubt it should be made quite clear that it was not intended, if once the county council purchased, that a district council should have any further option. There was also a question raised whether the county council, having purchased by agreement before the expiration of 21 years, would be bound by any obligation the district council had entered into. It should be made clear that the council would be so bound.

London County Council.—At the usual weekly meeting of the London County Council on Tuesday the Highways Committee recommended the Council to spend £80,000 on the acquisition of the property of the Gaslight and Coke Company known as the Pimlico gasworks as a site for an electricity generating station for the supply of current to the western portion of their tramways. In their report the committee stated that the site in question has a total river frontage of 320ft., about 81ft. of which is freehold, and the remainder is held on lease, expiring in 1925. The works are situated between Grosvenor-road and Pulford-street, and the committee are advised by the tramways manager and the electrical engineer that the site is an eminently suitable position for the establishment there of an electricity generating station to supply the necessary electrical energy for the working of any tramways which the Council may construct or reconstruct for electrical traction in the western half of the county of London. Moreover, in addition to the position being good for the purpose, the facilities afforded by the wharf frontage will be of great value in regard to the carriage by water of the large quantities of coal and other materials which will be required for use at the station when established. The price of £80,000 exceeds by £10,000 the original estimate for the land, and the committee asked for authority to expend that additional sum, as well as another £1,000 for legal and other expenses. In a supplementary report the Finance Committee stated that an offer has been received to acquire some further property in Pulford-street, involving an expenditure of £64,000, including provision for rehousing persons displaced. It is estimated, however, that there will be a recoupment of about £25,000 from the resale of certain of the property not required, so that the net cost of the whole of the property for the generating station will probably not amount to more than £120,000. At the same meeting the Highways Committee submitted a report with regard to the laying of stoneware ducts for the electric cables for the tramways now under reconstruction between Westminster and Tooting. They think it advisable that as the ducts will have to be placed, where practicable, within or alongside, or under footways near to, the tramway tracks, the work should be done by Messrs. J. G. White and Co., the contractors for the roadwork in connection with the reconstruction of the lines. The ducts will have to be placed in the positions which may be found to be most suitable, and as some will have to be laid in the carriageways and some in the footways, it is almost impossible to arrange a price, at per yard run, as would, of course, be desirable, for the whole of the work. The electrical engineer's estimate, which is in the circumstances necessarily only approximate, of the cost of this work and also of the necessary repaving work is £10,000. They have obtained from Messrs. J. G. White and Co. a schedule of prices which are within the engineer's estimate and are, they are advised, reasonable for the laying of the ducts, and this schedule they have approved. The prices for repaving the footpaths, which work they think should also be carried out by Messrs. J. G. White and Co., will depend upon the character of the present paving, and will vary from 2s. 2d. per square yard for relaying York paving to 10s. 7d. per square yard for asphalte paving 1in. thick. The expenditure for these works is provided for in estimates which have been approved by the Council. As will be seen from another column, the Highways Committee have recommended the acceptance of the tender of Messrs. Siemens Bros. for high-tension cables and that of the British Insulated Wire Company for low-tension cables at £31,743. 17s. 6d. and £49,499. 12s. 6d. respectively—total, £81,243. 10s. It is revealed by the full list of tenders received that that of the St. Helens Cable Company for each description of cable is the lowest, being £31,454. 12s. 6d. and £47,298. 5s. respectively, making a total of £78,752. 17s. 6d., or £2,490. 12s. 6d. less than the accepted tenders. As regards this, the report states that the samples submitted by the St. Helens Company were not of an entirely satisfactory character for the purpose for which the cables were required, and, moreover, that firm has not in either case submitted a complete tender, certain information having been omitted. The times for delivery specified by the British Insulated Wire Company and Messrs. Siemens are quite satisfactory, and the amount of their respective tenders are within the estimates of the Council's officers. With regard to the Council's northern tramways, the Establishment Committee presented a report stating that they had received a memorandum from the Highways Committee to the effect that they have had under

Digitized by Google

consideration the question of the steps to be taken with a view to the reconstruction, at as early a date as possible, of the Council's northern tramways, and in connection with this matter the committee have instructed the engineer to make a careful survey of the lines, including bridges, etc., in order to ascertain what difficulties are likely to be met with in carrying out the work. The work is of an urgent character, and the committee therefore propose to obtain additional assistance to enable the engineer to make the required survey as soon as possible.

LIGHTING AND GENERAL.

Tipton.—The Urban District Council's electricity order has been confirmed.

Lancaster.—The Town Council propose to borrow £25,000 for electrical purposes.

Leith.—Mr. A. Peden Rutherford has been appointed electrical engineer to the Corporation.

City Telephones.—Permission has been given to the Post Office to extend its telephone system to the Inner Temple.

Pontypridd.—The District Council intend to apply for sanction to a loan to enable them to carry out the electric lighting undertaking.

New Branch.—We are informed that Mr. G. Braulik has opened a branch at 115, Bath-street, Glasgow, for electrical supplies and accessories.

Dumfries.—The Town Council have appointed Prof. Capper, of King's College, to prepare a report on the proposed installation of electric lighting.

Willesden.—The polytechnic institute is to be lighted electrically. Mr. Frederic H. Taylor, consulting engineer, A.M.I.E.E., is dealing with the matter.

Scarborough.—The Telephone Sub-Committee have decided to apply to the Postmaster-General for a license to establish municipal telephones in the district.

Blaydon.—The Council are considering the lighting of Blackhall Mill by electricity. Mr. Berkley, manager of Hamsterley Colliery, is being consulted in the matter.

Sudbury.—An enquiry will be held on the 15th inst. into the Town Council's application to borrow £12,000 for electric lighting. The tenders received total £11,000.

Battersea.—The Borough Council have suggested to the London School Board that all its schools in the district should be lighted with electricity supplied by the Council.

Cheshunt.—Mr. H. Wall Wilkinson, M.I.E.E., A.M.I.C.E., Westminster, has been instructed to prepare a report on electric lighting for the Urban District Council.

Kettering.—Mr. H. P. Boulnois has held an enquiry into the application of the Urban District Council for sanction to borrow £43,275 for purposes of electric lighting.

Worcester.—The Council propose to apply for sanction to a loan of £1,000, repayable in 25 years, for defraying the cost of electricity meters and maximum demand indicators.

Derby.—The Parliamentary Committee have invited the Derby Chamber of Trade to send a deputation to the Parliamentary Committee to discuss the question of municipal telephones.

Dewsbury.—The electrical engineer has been instructed to lay down 90 yards of electric mains from the Market-place to the Masonic Hall in Longcauseway at an estimated cost of £40.

Ramsgate.—Application is to be made to the Board of Trade to extend the time for carrying out certain works under the Ramsgate Electric Lighting Order, 1900, for a period of two years.

Edinburgh.—An extension of the electric lighting of Causewayside is proposed. Eight lamps will be required, which, at £13 per lamp, represents an additional expenditure of £104 a year.

Market Drayton.—The Parish Council have decided to support the application of the Market Drayton Electric Light and Power Company's application for a license to supply electricity in the district.

Newark.—The Electric Lighting Committee of the Urban District Council are reported to have come to a final arrangement with an electric lighting company, which will be brought before the Council shortly.

Wolverhampton Exhibition.—We are informed that the Brockie-Pell Company have some 300 to 350 lamps now lighting the exhibition buildings and grounds of the Wolverhampton Exhibition opened on May 1.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board have elected a Liverpool architect to design and superintend the erection of buildings for the generating station and transformer stations.

London Gazette.—A first and final dividend of 2s. 3d. per pound has been declared in the estate of T. Morley, electrical engineer, 16, Whalley-road, Accrington. Payable from May 8 at official receiver's offices, 14, Chapel-street, Preston.

Runcorn.—A syndicate proposes to apply for parliamentary powers to erect electric generating stations and lay mains for the supplying of electricity throughout a district comprising the county of Chester and the northern portion of the county of Stafford.

Deptford.—Messrs. Handcock and Dykes, electrical engineers, of Victoria-street, have been engaged by the Borough Council to prepare an estimate and specification for wiring and providing the necessary fittings for lighting the town hall with electric light.

Hackney.—At the meeting of the Borough Council last night the following extensions of mains were recommended: to Filey-avenue, Clapton Common, amounting to £395; also to Station-buildings, Haggerston, amounting to £105—making a total of £500.

Amalgamation.—It is reported that the Helsby Company and the British Insulated Wire Company have amalgamated. The combination is expected to have an important effect upon the ever-growing foreign competition in the great industry of cable wire making.

Brighton.—Mr. Christie, the resident electrical engineer at Brighton, brought the Nernst lamp to the notice of the Electric Lighting Committee, who have authorised him to fit up 10 street lamps in the Montpelier district with it. The result appears to be very satisfactory so far.

Covent Garden.—The huge glass chandelier, the largest of its kind ever brought into a theatre, has been removed from Covent Garden Opera House. Weighing many tons, it has been supported by massive chains for more than 40 years. Light from the roof will in future be supplied by two circles of incandescent lamps.

Chelmsford.—The Town Council have agreed to pay the Chelmsford Electric Lighting Company's account of £335. 10s. 6d. for the quarter's lighting, less £2. 0s. 3d. deducted for lamps not kept alight, and to place three lamps in Manor-road, two in Marlborough-road, and one each in Redcliffe and Upper Roman roads.

Presentation.—Last Friday Mr. J. Gray Scott, the Leith Corporation's electrical engineer, was presented by the staff at the electric lighting station with a smoker's cabinet, on the occasion of his leaving to take up a similar position at Croydon, as a mark of their appreciation of the unfailing courtesy Mr. Scott had always shown them.

Hull.—The electrical engineer has been authorised to lend lamps and fittings for illuminating the town hall in connection with the Coronation celebrations free of charge. The resumed conference between a deputation of the Telephone Committee of the Corporation and the directors of the National Telephone Company has been adjourned.

Frome.—The scheme of electric lighting for the town is to be proceeded with, and at the July meeting of the Council a resolution will be submitted providing for application for sanction to the loan, and for arrangements to obtain tenders either for carrying out the work in the usual manner, or for carrying it out and insuring the Council against loss.

Barnstaple.—The Electric Lighting Committee have appointed Mr. T. B. Johns, of Bristol, as clerk of works to superintend the erection of the electric light station. Steps are to be taken to obtain a loan of £21,600 for the purpose of electric lighting in the borough. The front elevation of the lighting station against Castle-street will be of white Marland brick.

Londonderry.—Mr. Macrory, the electrical engineer, in his last report states that the first section of the cable conduit system has been completed, and several conduits saved, owing to several diversions and alterations from the original scheme. It is anticipated that there will be sufficient electrical power at the station to light the city gates on the occasion of the Coronation festivities.

Stock Exchange.—The Stock Exchange Committee has been asked to allow the following securities to be quoted in the official list: British Westinghouse Electric and Manufacturing Company's further issue of 50,000 6 per cent. preference shares of £5 each, fully paid; Edmundson's Electricity Corporation's further issue of 10,000 6 per cent. cumulative preference shares of £5 each, fully paid.

Eccles.—At the last meeting of the Public Lighting and Electrical Supply Committee, the question of the transformer required in respect of the electric lighting of St. Andrew's Church was referred to the Works Sub-Committee. An application was submitted for the lighting of Lewis-street, Patricroft, and it was resolved that, subject to the street being kerbed and channelled, the necessary number of lamps be erected.

Grimsby.—Particulars of tenders accepted by the Corporation for plant required to meet the load next winter will be found in another column. On April 8 the town clerk received the sanction of the Local Government Board to borrow an additional £17,000, £4,000 being for accounts overspent and £12,900 for extensions of plant and mains. This makes the total capital expenditures sanctioned by the Local Government Board £72,000.

Blackburn.—The president of the Institute of Civil Engineers having nominated Prof. Kennedy as referee in the dispute about the engines and dynamos for the electricity works, some 213 sets of tenders for engines, of types varying from 90 to between 300 and 400 revolutions a minute, were submitted to him, and he has selected three of moderate speed—180 revolutions per minute—from which the committee will make the final selection.

Electric Lighting Orders.—Bills to confirm electrical lighting provisional orders which have been granted to the Blaydon Urban Council and the County of Durham Electric Power Distribution Company in respect of Chester-le-Street, the Newcastle and District Electric Lighting Company (for Newburn), and the Northern Counties Electric Supply Company (for Earsdon and Tynemouth rural), have been reported to the House of Commons.

Bath.—Mr. Bicknell has held an enquiry into an application by the Corporation for a loan of £25,000 on account of the electric lighting. The sum is made up of two amounts, £11,195 being excess of expenditure over loans previously sanctioned, and £13,000 for new plant and alterations in the system of working immediately required to be expended to enable the works to be carried on during the next winter if the breakdowns of last winter are not to recur.

Electric Furnaces.—Three electric furnaces of 500 h.p. are said to have been erected in the valley of Camonica, Northern Italy, for the manufacture of pig iron under the Stassans patent. The furnaces in general outlines resemble cupola furnaces using coke, their special feature being apparent in the provision made for supplying electric current and in the electrodes placed at the bottom of the boshes. To obtain a metric ton of metal 3,000 horse-power hours are required.

Digitized by Google

Mansfield.—On Tuesday the Mayor (Councillor T. Taylor) and Councillor W. J. Chadburn laid the foundation stones of the electricity works and refuse destructor, which the Corporation are constructing at an approximate cost of £60,000. The engineer is Mr. Robert Hammond, Westminster; the builder Mr. Robert Greenwood, Mansfield; and the architects Messrs. Vallance and Westwick, also of Mansfield. The Corporation anticipate to be able to supply power by November.

Hoole.—At the last meeting of the Urban District Council a letter was read from Messrs. Rowcliffe and Co., solicitors, Manchester, notifying the Council of their intention to apply on behalf of a syndicate for parliamentary powers to carry out the electric power scheme for Cheshire and North Staffordshire. The scheme would be on the lines of the Lancashire Electric Power Act. The chief object was to supply electricity for power purposes. The letter was allowed to lie on the table.

Blackpool.—The borough engineer and tramway engineer is to report on the best means of laying electric cables in the widened promenade for lighting and traction purposes. Applicants for extensions are in future to be asked to pay 6 per cent. towards interest and sinking fund of cost of the same until that sum has been assured by additional consumers. From March 31 the practice of charging by the maximum demand indicator for public street-lighting is to be discontinued, and a uniform charge of 3½d. per unit will be made.

Personal.—Mr. A. Venning, who has been chief engineer of the steam engineering and central-station department of the British Thomson-Houston Company, Limited, during the past five years, has now resigned his position with that company. He has had charge of the design of several of the largest and most important generating stations erected in this country by the above company, his latest work being in connection with the plants of the Great Northern and City Railway and Chatham tramways, both of which stations are almost ready for opening.

Fire.—We are informed that Mr. A. H. Hunt, whose premises at Gresham-street were recently destroyed by fire, has now started again at his new and more commodious address, 115-117, Cannon-street. Mr. Hunt is supplying the trade only, and among some of his specialities may be mentioned automatic distance switches, circuit breakers, iron case fuses, fuseboards, switchboards, fancy and cut glass shades and globes of English manufacture, etc. He is also representing the Walsall Electrical Company for the sale of their switchboard specialities and other apparatus, and Messrs. Geoffroy and Delore's for wires and cables.

Malton.—At the last meeting of the Urban District Council Mr. Fairweather and Mr. Brown, the engineer of the Northern Counties Electricity Supply Association, stated that they had been inspecting certain parts of Malton with the view of securing a site for their working plant, etc. They had already obtained an order from the Board of Trade enabling them to generate and supply electricity for the town, and they had contracted to instal electric light for public lighting purposes by July next. The consideration of a letter from the Postmaster-General with reference to the establishment of the telephone in Malton was postponed.

Manchester Telegraph Messengers' Institute.—The library which has been established in connection with the Manchester Postal Telegraph Messengers' Institute was opened this week by the Postmaster of Manchester (Mr. Phillips), who gave a short address to the boys. About a thousand volumes of books suitable for boys have been collected, and Mr. Phillips expressed the gratitude felt by himself and the committee of the institute to the donors. He also announced that the cricket, tennis, and cycle clubs, which form part of the institute, will begin their season next week. The swimming club is already a great success.—*Manchester Guardian.*

Colchester.—The Electric Lighting Committee have passed through a most difficult year. The pressure of supplies has been doubled through the entire system, and it was thought well at the same time to reduce the price of current to consumers. It was estimated that the utmost they could expect was to sell 180,000 units at a net profit of £110, but the result of the year's working shows a sale of 180,166 units at a net profit of £153. 4s. 10d. The income from private consumers has considerably exceeded the estimate, and the total net profit is £473. 18s. 4d. for the year, and would have been more had not much of the barrack occupation remained unoccupied during this period.

Worthing.—The Electric Lighting Committee have been authorised to construct the new buildings in connection with the contemplated extensions of that undertaking under the personal supervision of the borough surveyor, and the latter's salary will on the completion of the work be increased by 70 guineas. The estimated cost of the particular work is £3,500. The Council have decided to sanction the employment of the arc lamp columns in any scheme of decoration at the Coronation subject to the approval of the resident engineer. There are now applications equivalent to 8,600 8-c.p. lamps at hand; 6,700 of these are connected, and, as far as can be foreseen, by the end of July the whole of these applications will be connected up, which will test the existing machinery and plant to its utmost capacity.

Electric Barges.—The scheme for widening and deepening the Severn and the Birmingham and Worcester Canal, so as to form a continuous water route for vessels of 300 tons burden from the Midland metropolis to the sea, says the *Western Mercury*, has been hanging fire since the refusal of the Birmingham Corporation to join the Corporations of Worcester and Gloucester in guaranteeing the preliminary expenses connected with the obtaining of parliamentary powers. The committee (of which Sir Alfred Hickman, M.P., Sir John Gunn, of Cardiff, and the Hon. G. Allsopp, of Worcester, are prominent members) have, however, not abandoned their object, and hope to secure the co-operation of capitalists and the leading manufacturers of the Midlands in raising the necessary funds to place the scheme on a practical working basis. An important feature of the scheme is the proposed introduction of steel barges worked by electricity.

Epsom.—The Lighting Committee have re-elected Mr. Ledger as chairman. The resident electrical engineer in his last report states that the supply of current is continuous, and the machinery at the electric lighting works work satisfactorily. He also reported that a great many glasses appeared to be wilfully broken by stones, and the Council were recommended to bring the matter to the notice of the police and to issue a reward. The engineer is to be granted permission to take a student. With reference to the new £10,900 loan, the Council will instruct Mr. Hawtayne to take the necessary steps to get tenders for the increase of the generating plant, boilers, dynamos, etc.

York.—The Electric Lighting Committee propose to extend the main in Monkgate for the lighting of additional street arc lamps as required by the Streets and Buildings Committee and for private consumers, also to extend the main from Driffield-terrace to the city boundary on the Tadcaster-road at the estimated cost of about £1,000 altogether, to supply private consumers. In giving evidence on behalf of the Corporation's Bill before a Select Committee on Monday, the Town Clerk said they were increasing the generating station and extending their system. They had borrowed £40,000, and had applied for a new loan of £60,000. The revenue of the undertaking had largely increased, and they were putting up additional buildings and plant. The clauses were passed, as were those giving the Council power to supply energy outside and to companies and tramways, and the power to give 10 per cent. discount for prompt payment of electric accounts.

Coronation Illuminations.—The City will devote a sum of £500 to the decoration and illumination of the Royal Exchange, the pediment of which will be outlined in ruby lights, and it is also probable that the general scheme which was so successful at the Mansion House at the Diamond Jubilee will be, to a large extent, followed in the Coronation festivities. All the great banking and mercantile houses in the vicinity of the Lord Mayor's official residence are pushing forward their preparations for illumination. The Paddington Borough Council have voted £500 towards the decoration and illumination of the local public buildings and main thoroughfares. The Kensington Borough Council have voted £500; Hammersmith Borough Council, £1,350; and it is proposed that the London County Council should vote £3,500. The Lewes Electric Supply Company have decided to suspend the operation of the "maximum demand" system during the month of June, so that consumers may let themselves go without fear of more than trifling expense.

West Hartlepool.—About 9 p.m. on Thursday a considerable proportion of the electric lighting service temporarily failed. At the Grand and Gaiety Theatres there was a short delay before the gas supply replaced it, but no panic occurred It was reported at Tuesday's Town Council meeting that the amended draft licence had been received from the Postmaster-General for the establishment of a municipal telephone exchange for the Hartlepools, and that it had been decided to take out specifications, etc., for the work. It was pointed out the Corporations were not by this finally committed to go on with the scheme. Upon Coronation Day current will be supplied free to consumers for the illumination of their premises, subject to the fittings, etc., being to the satisfaction of the electrical engineer. The electrical engineer, Mr. Friederichs, has been instructed to report on the request by the Hartlepool Corporation for terms for the supply of electrical energy in bulk at the boundary of the borough, and the terms for distributing the same within the borough.

Birmingham.—An enquiry has been held into the Council's application for consent to borrow £251,974 for electric supply by Mr. E. A. Sandford Fawcett. Mr. E. O. Smith, town clerk, and Mr. Vaudrey, the city electrical engineer, gave evidence in respect of the scheme, from which we note that the sum sanctioned was considerably more than was actually asked for. This was due to the circumstance that certain work which was in contemplation at the time was not now proposed to be carried out. The cost of the site in Summer-lane was £23,174. The opportunity of the city authorities acquiring such a desirable site did not often occur. The amount proposed to be expended upon machinery, new buildings, and additions to existing power stations in Water-street and Park-street was £41,909. 3s. 2d., and the erection of the new generating station in Summer-lane was set down at £128,890. The estimated cost of laying new mains, in erecting and equipping a subsidiary station, providing meters, etc., was £58,000. With regard to the present generating stations in Water-street, Dale-end, and Parker-street, it was anticipated that they would be working at their full capacity in 1903. There was not sufficient land at those stations for the extension of the works.

Dudley.—At the Town Council meeting on Wednesday it was stated that the estimated revenue for the 12 months ended March 31 had been £6,117. 13s. 3d. The sum of £636. 7s. 4d. was put down in respect of the loss sustained with the meters. In addition to this, there was the interest on the money lying in the bank, amounting to £80, and the value of the stores, representing a sum of £62, making the estimated total on the credit side of the accounts £6,816. 6s. 7d. The expenditure had been £6,648. Deducting the expenditure from the gross estimated receipts there was a net profit, after paying interest on sinking fund, of £168. 7s. The number of units generated during the year had been as follows: 688,678 for traction purposes, 238,292 for private lighting, 37,335 for street-lighting, 10,148 for lighting the station, and 3,126 for testing purposes. The selling price of the electricity had only averaged 1½d. per Board of Trade unit. He was quite convinced that the town would ultimately derive a tremendous benefit from the electrical undertaking. The Town Clerk (Mr. Brettell) said that £41,500 of the capital in connection with the electrical undertaking had been expended, and sanction had been given for the borrowing of further loans amounting to £23,000, making a total of £64,500.

Digitized by Google

Cheltenham.—The Corporation have replied to the Gloucestershire County Council that they are willing to supply electric power to work a light railway between the Cross Hands Inn at Brockworth and the city boundary of Gloucester, in the event of the County Council making and constructing such a line and desiring to take such power from the Cheltenham Corporation. The electrical engineer in his last report states that the equivalent of more than 36,000 8-c.p. lamps are now connected to the private supply mains. The Council have decided to increase the electrical engineer's salary to £450 per annum from Dec. 31 last and to £500 per annum from June 30 next.

Ipswich.—The Town Council have arranged with the Great Eastern Railway Company for the construction of so much of the siding as is upon the company's premises upon the following terms: the siding, points, and other works will be constructed by and at the expense of the company, and kept in repair by them, the Corporation paying to the company the sum of £50 a year for the accommodation, but against this annual sum the company will credit the Corporation with a rebate of 5 per cent. on the amount received by the company for the carriage of traffic over their system on to the said siding. The committee would also arrange with the company that they should forthwith construct at the expense of the Corporation so much of the siding as is on the Corporation's property. The estimated cost of this portion is £750.

Dartmouth.—We quote from the circular issued to Dartmouth householders by the Urban Electric Supply Company, Limited the following terms: "Free wiring—The company is prepared to fit up premises free of all initial cost to the occupier, charging in all ordinary cases a rental of 4½d. per lamp per quarter, and giving the consumer the opportunity of buying it outright at any time. Price of current—For any quantity up to the amount which would have been used if the 'maximum demand' had continued for 91 hours during the quarter (one hour per day), lighting 7d. per unit, power for motor 4d., for any further quantity 4d. and 1½d., for heating 2½d. per unit for any quantity; rent of meter, main cut-out, and maximum demand indicator, up to 50 8-c.p. lamps, 2s. per quarter; ditto over 50, 4s. per quarter. Prepayment meter—Lights will be supplied for small premises through prepayment meter (1s. or penny-in-the-slot meters) at 6d. per unit, which covers the rent for the wires and rent of meter."

Hastings.—The report of Prof. Kennedy upon the electric light undertaking, submitted to the meeting of the Council last Friday, has been circulated amongst the members. The *Hastings and St. Leonards Observer* understands that it is of a very satisfactory character, and says it seems a pity that it should not have been made public by being supplied to the Press. The professor enters into a lengthy review of the whole of the machinery, etc., and is most complimentary about the whole concern. Amongst other things, he points out that the plant is capable of doing quite 50 per cent. more business than is done at the present time, refers to the up-to-date character of the machinery, and speaks in high terms of Mr. Leonard Andrews, the electrical engineer. Mention is made of the failures experienced formerly in the light, but he points out that certain matters have been perfected, and there is less chance of such failures happening in the future, and he does not think there should be much cause for complaint as time goes on. The whole report is very complimentary and satisfactory. Allusion is also made to the economical way in which the works are managed.

Stockton.—On Tuesday a report was presented to the Town Council by Mr. J. J. Smith, the electrical engineer, on the question of the extensions to the electric light works, the expenditure for which has been sanctioned by the Local Government Board. The sum of £21,000 has been granted for new machinery and electrical equipment only, and does not include any expenditure that might be required on alterations to buildings. The expenditure on some of the items, he says, would certainly be exceeded; it was hoped that there would be a saving on others, but still he did not expect that there would be any margin as a surplus. The Electric Light Committee resolved that the engineer be instructed to prepare the necessary plans and specifications and to invite tenders for the machinery and works mentioned in his report. The gas manager reported that despite the introduction of electric light in the town, and its increase of popularity amongst the ratepayers, there was an increase of 157,000 cubic feet in the make of gas at the Corporation works during the past month, compared with the corresponding period of last year, when the total make was 33,889,000 cubic feet.

Darlington.—Mr. J. R. P. Lunn, in his last report, stated that four consumers were connected during the month, making a total of 148. Two hundred and seventy-three 8-c.p. lamps were connected, making a total of 11,058. He had applications from 33 intending consumers who would require 2,390 8-c.p. lamps; 14,416 units were generated, the revenue from which would be about £220; 518 yards of pilot and feeder cable and 1,190 yards of distributing cable were laid in the following roads: Carmel-road, Woodlands-road, Blackwell-lane, Coniscliffe-road, and High-row. During the year ending March 21 82 consumers and 5,925 8-c.p. lamps were connected. The engineer recommends that in future consumers of electrical energy be informed that all wall plugs connected to circuits which are supplied through the lighting meter must be of the two-prong type, and all wall plugs connected to circuits which are supplied through a power or heating meter must be of the concentric type. The annual statement of revenue and estimate of expenditure for the year ending March 31 shows a profit of £90. 1s. 11d. Messrs. Kennedy and Jenkin will be asked to advise as to what extension of the electric lighting generating station will be necessary in order to supply the electrical energy required for the Darlington light railways.

Institution "Journal."—The *Journal* of the Institution of Electrical Engineers, edited by Mr. W. G. McMillan, secretary, Part No. 156, (E. and F. N. Spon, Limited, 125, Strand, W.C.; 6s.), contains the following papers with the discussions thereon: "Researches on the Electrical Conductivity and Magnetic Properties of upwards of 100 Different Alloys of Iron," by Prof. W. F. Barrett, F.R.S., member; "Electric Shock and Legislation thereon," by Major-General Webber, C.B.; "Electric Shocks," by Mr. F. B. Aspinall, member; "Electric Shocks at 500 Volts," by Mr. A. P. Trotter, member; "Surface-Contact Systems of Electric Traction" (in abstract, Birmingham Local Section), by Mr. W. Kingsland, member; "Some Notes on Electrical Engineering Practice in Europe and America" (Cape Town Local Section), by Mr. John Denham, member; "Practical Notes on Continuous-Current Distributing Mains" (Glasgow Local Section), by Mr. J. C. A. Ward, associate; "The Supply of Electricity in Bulk" (Manchester Local Section), by Mr. H. A. Earle, member; together with the inaugural address of the chairman of the Dublin Local Section, Prof. W. F. Barrett, F.R.S., and two original communications from Mr. David Robertson, B.Sc., entitled "A General Formula for Regular Armature Windings" and "A Method of Studying Armature Windings by Means of Winding Diagrams."

New Issue.—The Bournemouth and Poole Electricity Supply Company, Limited, are issuing preference shares carrying £6 per cent. cumulative dividend. The rate of interest paid on the ordinary shares of the company was 4 per cent. for 1898, 5 per cent. for 1899, 6 per cent. for 1900, and 7 per cent. for last year, and the prospectus contains the following statement: "The directors anticipate that at Dec. 31 next the balance of profits remaining after paying all interest charges, and the dividend on the existing preference shares, and after providing for depreciation, will suffice to pay the dividend on the present issue of preference shares, and at least a dividend of 7 per cent. on the ordinary shares for the current year." The company is entitled to parliamentary powers in Bournemouth, Boscombe, Winton, Southbourne, Christchurch, Parkstone, and Poole, and the Board of Trade have within the last few days decided to grant a provisional order to the company for the area of Pokesdown. At the present time the number of lamps connected to the company's mains are equivalent to 69,795 of 8 c.p., over 12,000 of which were added during the past year. The supply mains have been recently extended to Parkstone and Poole, the company is supplying the motive power for the tramways from County Gates to Poole, and are making arrangements to supply the projected line from the borough boundary to Christchurch on the east side.

South Africa.—We glean from the *British and South African Export Gazette* as follows: The Bloemfontein Town Council have obtained authority to raise a loan of £25,000 for the extension of the electric lighting system. If the powers being sought by the Paarl Electric Power Syndicate, Limited, Cape Colony, are granted, valuable orders for electric lighting, traction, and telegraph and telephone material will be given out at an early date. The syndicate's aims comprise all the necessary works for the furnishing of an electric lighting and power supply installation, a tramway service, and a telephone and telegraph service, and include the building of reservoirs, aqueducts, the construction of a power station, etc. Electric lighting and tramway installations are mooted for Walmer, a Port Elizabeth suburb. The construction and equipment of a central power station for lighting and tramway purposes will shortly be undertaken by the Pretoria Town Council. The Borough Council of Kimberley have obtained the necessary sanction to borrow £10,000 for the extension of the electric lighting system, on the condition that it is first ascertained, by consultation with the directors of the De Beers Company, that the latter cannot deliver current to the Council at a lower rate than they themselves can produce it. Should the company be able to supply current on advantageous terms, the above loan will be diverted to cable extension and other works.

Bankfoot.—From the *Auckland Chronicle* we gain particulars of the laying down of a large electric plant at Bankfoot. Messrs. Pease have an electrical lighting installation at Peases West on the parallel system, which has been in vogue some two years or thereabouts. However, the firm are now introducing coal-cutting machines for long wall work, 110 yards back and forward to work in a clay seam or seams. An electric ram is being fitted by a German firm at the ovens, which will load, press coal in, and push coke out. The weight of the ram is 70 tons. It will have two motors in it, and its strength is 30 h.p. The Bankfoot works will be lighted up by the new plant on the series system, the French ovens having five arc lamps of 1,000 c.p. each. The engine to drive the whole of the electric plant is one of Robey's, of Lincoln. It is 320 i.h.p., and horizontal. Instead of a belt it will have 13 ropes, the fly and driving wheels having grooves. The dynamo, which is not as yet put down, will have a capacity of 500 volts and 400 amperes. This will drive four coal-cutters, the machines in the fitting shops, and the Bankfoot electric lighting installation. The station at Bankfoot, which is almost complete, has accommodation for another similar set if required. The Crook Urban Council are anxious for the electric light, and may, perhaps, here see their opportunity. Messrs. Reid and Ferens and Messrs. Scott and Mountain, of Newcastle, have the bulk of the electrical work in hand. Mr. S. Wraith, Messrs. Pease's electrician, is held responsible for this department, whilst Pease's general engineer is Mr. Wm. Oughton, of Stanley, and their chief agent is, of course, Mr. T. Y. Greener.

Southampton.—Colonel W. R. Slacke has held an enquiry into the application of the Corporation for sanction to borrow £30,000 for purposes of electric lighting. Alderman Bone, chairman of the Electricity Committee, said the proposed extension was due to increased demand for lighting, and also to the increase in the town itself. The area of the lighting was the same as the borough boundaries. They had also to provide for the extension of lighting and for the electric trams. At the present time they were charging 5½d. for light and 3d. for power, except in regard to the trams, which were their own undertaking. The electric light was commenced by a company, who got their license in 1890, and a further order in 1895. They commenced lighting about 1892, and the undertaking, which was a small one, was purchased by the Corporation in 1896. As far as the

Digitized by Google

Corporation were concerned it had not been a remunerative undertaking. There was a small deficit up to last year, when there was a profit. Mr. Street, electrical engineer, gave evidence as to the capacity of the plant at the works, and said the extension of the existing works was not considered desirable, as they would have to pay a very high price for the land, and it would involve the removal of buildings. It was also unsuitable, because there was not available depth between the streets. They had estimated to provide on the site for two 500-kw. machines and the necessary buildings. All the plant at the present station was worked by one 500-kw. dynamo, and they had no reserve whatever. Extra provision for the trams would have to be made in the near future. It was also stated that at their last meeting the Council had decided to apply for power to borrow a further £2,500 to provide for distributing mains and services, so that they might connect customers when necessary. The inspector said that would have to form the subject of a further enquiry.

Cardiff.—Mr. Arthur Ellis has prepared a statement showing approximately the revenue, expenditure, and rentals of the electric lighting department for the year ending March, 1902. The gross expenditure has been £9,594, and £5,676 has been spent in loan charges, interest, and sinking fund—a total of £15,270. This shows an approximate profit of £1,023, as against a profit of about £9 for the previous year. The engineer adds that the gross profit works out to about 6½ per cent. on the capital. The statement is regarded as highly satisfactory. At the suggestion of the engineer it has been decided to extend the electric lighting mains at an estimated cost of £708. The Western Mail Limited have now added to their establishment a powerful electric light signal, which is described in a recent issue. The flat roofing of the higher turret of the journal's premises at the head office in St. Mary-street, Cardiff, has been regarded as the highest accessible altitude in the town, standing, as it does, 116ft. from the ground. Upon this an iron staging has been erected, about 30ft. high, and this is fitted with an electric lamp of 6,000 c.p. The staging is made in the form of an outer cage, within which the lamp may be moved up and down by the use of hand winches, and the lamp itself is hung in a movable inner cage, designed so that it may be adapted for signalling purposes. The signal throws a strong light over a wide area, and, by reason of its strength and the elevation that it occupies, may be seen practically all over the town, and even from some parts of Penarth and Rumney. It will be used for notifying to people of the town and neighbourhood when any remarkable events occur, of such events as the Anglo-American boat race and of the polings during elections in a manner that will be sufficient indication to the people of a wider area. Messrs. Clay Bros. and Co., Cardiff, have supplied the electrical fittings, and the current will be derived from the *Western Mail* generating plant.

Kingston.—The arc lamp question was discussed at the last meeting of the Council, and finally the following minutes were adopted: "At a meeting held on April 18 the action of the public meeting appears to have been discussed for the first time, the following reference appearing in the minutes of the committee: 'The committee had before them the following resolutions adopted at a public meeting held on the 13th ult., and referred by the Council to this committee—viz.: (1) That this meeting of burgesses emphatically condemns the extension of the arc lighting system in the main roads of the borough, and calls upon the Corporation to forthwith withdraw the order for 35 additional arc lamps passed by the Town Council at its meeting on Feb. 18; (2) that in the opinion of this meeting the present financial position of the borough electric lighting undertaking demands searching investigation, and the Town Council are hereby requested to take into their earnest consideration (1) the advisability of discontinuing the whole system of arc lighting in the streets, and (2) the means to be taken to make the private lighting into a commercial success.' Resolved that in regard to such resolutions this committee would remind the Council that the proposal to extend the arc lighting was approved so far back as 1900, that by the authority of the Council application was made to the Local Government Board for borrowing powers for the purpose, that the Local Government Board held a public enquiry on the subject on Jan. 8, 1901, and sanctioned the loan on March 13, 1901, and that orders for which the Corporation are now liable were authorised and given for a portion of the necessary plant in June, 1901, and subsequently for other portions of the plant. Therefore, having regard to all the circumstances, the committee cannot recommend the Council to attempt to withdraw their orders for carrying out the work which was decided upon after the most careful consideration. The further suggestion contained in such resolutions, that the whole system of street-lighting should be discontinued, the committee consider to be impracticable as involving unjustifiable financial sacrifice and a serious diminution of efficient lighting." During the discussion the Electrical Engineer (Mr. J. E. Edgcome) said it was only fair to Mr. A. H. Preece, under whom the present system was installed, to say that at the time it was laid down it was impossible under the regulations of the Board of Trade to put in any other system. Two years afterwards there was a radical change in the regulations, so that those municipalities which had laid down systems since 1895 had an advantage which was not open to Kingston in 1893. When statements were made that the original scheme was a wrong one, it was right to say that it was the only scheme that could be proposed at that time.

Colne.—Mr. A. G. Cooper, borough electrical engineer, has submitted the following report on the past year in his department: "Since my last report the plant mentioned therein as having been ordered has been set to work, and has run continuously up to the present. The steam-turbine was erected, together with the switchboard and balancers, in some five or six weeks from being delivered, and the current was first switched on to the mains for public use on Sept. 23 last. The conditions of supply were somewhat onerous, as the switchboard and balancers had to be housed in a temporary lean-to roof in the engine-room of the new works, but the committee had promised that the current should be available for use at the technical schools on the date mentioned above. As the building of the generating station in Phillips-lane progressed (which has been, unfortunately, slow owing to the failure of the contractors) further plant was ordered, consisting of a 30ft. by 8ft. Lancashire boiler, superheater, economiser, feed pump, etc., from Messrs. Yates and Thom, Blackburn, and a 160-kw. Belliss-Greenwood steam dynamo. The pipework incidental to this plant is being erected by Messrs. James Carter and Sons, Stalybridge. The engine-room is spanned by an overhead travelling crane made by Messrs. Rushworth Bros., Colne. The storage battery was set to work during the latter end of the year, and this enables a supply to be given continuously throughout the 24 hours, the same coming into operation when the engines have been shut down. The original generating plant at the refuse destructor will work in conjunction with the machinery in the main station across the river, steam being raised to drive the engine from the heat derived from burning refuse, which previously escaped up the smoke stack. The efficiency of the destructor as a destroyer of waste products is not affected thereby. Further generating machinery will be installed immediately on the construction of the Colne and Trawden light railway, the Corporation being bound to supply current for this purpose. A word as to the distributing system. The current is conveyed on paper-insulated lead-covered feeders in earthenware conduits to three feeding points situated at the technical schools, Dockray-street and Keighley-road. At these points the feeders are coupled to switchboards located in large chambers underground. From here the distributing or branch mains radiate in all directions. The financial result of the first three months' working—from Sept. 23, 1901, to Dec. 31—was as follows: Some 23 consumers have been permanently coupled to the mains, representing an equivalent of 1,578 8-c.p. lamps and one 6-h.p. motor. The revenue for the three months amounted to £86. 12s. 2d., exclusive of meter rents, etc., the average price for current working out from all consumers at the very satisfactory price of 4d. per Board of Trade unit."

London County Council.—The Council's Electric Supply Bill has failed to pass the Select Committee of the House of Commons. Practically the whole of the electric supply companies of London petitioned against the Bill, as well as the City Council of Westminster. The opponents contended that the proposals of the Bill would effect a breach of a parliamentary bargain, both as to the period within which local authorities might purchase electric undertakings, and in the respect that it would give the County Council power, not possessed by them at present, to purchase these concerns. On Tuesday last the Council granted an application of the Poplar and Stepney Sick Asylum District Managers for a loan of £2,200 for the installation of electric light in their asylum. The following notices under Electric Lighting Acts and Orders were agreed to: From the Brompton and Kensington Electricity Supply Company, under the House-to-House Order, 1899, of intention to lay low-tension mains along a portion of Cromwell-road; the Charing Cross and Strand Electricity Supply Corporation, under the St. Martin's District Order, 1899, and the company's Further Powers Act, 1900, to lay extra high-tension mains along portions of St. Martin's-lane, Garrick-street, Hart-street, Wellington-street, Bow-street, Long-acre, Endell-street, and Milford-lane; the Kensington and Knightsbridge Electric Lighting Company, under the company's order and the Kensington and Knightsbridge Electric Lighting Act, 1893, to lay mains along Burden-mews, King-street, Ball-street, and Young-street; the St. Pancras Borough Council, under the St. Pancras (Middlesex) Order, 1883, of intention to lay mains along Osnaburgh-terrace. A notice was received from the Bermondsey Borough Council, under the Bermondsey Order, 1899, of intention to lay mains, for the purpose of public arc lighting, along a portion of the Council's subway in Tower Bridge-road. The Borough Council is the undertaker under the order, and the Council have no power of approval or disapproval of works. The order contains, however, the usual clauses relative to the Council's subways. Another similar notice, from the Hammersmith Borough Council, under the Hammersmith Order, 1893, referred to intention to lay mains along portions of King-street and Standish-road. The supply of electric current to the Horniman Museum occasionally fails, placing the whole building in darkness. When this happens it is difficult for visitors to find their way out, as in both galleries the floor is covered with show-cases, and persons are liable to fall against the cases and injure themselves with the glass. Moreover, the confusion caused by the sudden darkness affords any evil-disposed person an opportunity of abstracting valuable articles from the collection. It is, therefore, proposed that when carrying out the alterations in the electric installation, already approved by the Council, the engineer should arrange for some of the lamps to be fixed on a special circuit, and for a small battery of accumulators to be provided, so that in case of emergency these lamps could be lighted for so long as it might be necessary to enable the building to be cleared. The cost of carrying out the arrangement is estimated at £260.

PROVISIONAL PATENTS, 1902.

APRIL 28.

9780. An improved fitting for electric incandescent lamps. Johann Kremenezky, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

9800. Improvements in switch or ringing keys for telephone switchboards. Lars Magnus Ericsson, 4, South-street, Finsbury, London. (Complete specification.)

9801. Improvements in telephone jack-strips. Lars Magnus Ericsson, 4, South-street, Finsbury, London. (Complete specification.)

Digitized by Google

9788. Improvements in electric switches and in the application of the same to electrically-propelled vehicles. William Milton Brown, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

9789. Improvements relating to electric railway systems, and more particularly to crossings and switches for the same. Herbert Elijah Keeler, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

9803. Improvements in and relating to the electrolytic decomposition of alkaline salts. Meyer Wildermann, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

APRIL 29.

9815. Improvements in and connected with the provention of sparking on the interruption of ethereal telegraphic and other electric circuits. William Lloyd Wise, 46, Lincoln's-inn-fields, London. (Kristian Birkeland, Norway.)

9819. Improvements in insulators for supporting overhead electrical conductors for electric tramways and the like. John Berry Smith, 5, Blakiston-street East, Fleetwood, Lancs.

9825. Improvements in or relating to electric fuse boxes for street mains and analogous uses. Robert Frederick Hall, 24, Temple-row, Birmingham.

9836. Improvements in apparatus for working trolleys used in connection with overhead wires in electric traction. Walter B. Smith and G. Napier and Sons, Limited, Grant and Maddison's Bank-buildings, Canute-road, Southampton.

9849. Improved means or method of connecting incandescent electric lamps in festoons, and for other like temporary uses. William Barker, 254, Colne-road, Burnley. (Complete specification.)

9865. Improvements in electrical ignition devices for internal-combustion engines. Robert Samuel Lovelace, 70, Chancery-lane, London.

9873. Improvements in and relating to the connections or joints of cables for conveying electrical energy. Alfred George Brookes, 55, Chancery-lane, London. (Harry Grant Thompson, United States.)

9885. Improvements in electrical rock drills or rock-drilling machines. Arthur Henry Gibson, 40, Chancery-lane, London.

9895. Improvements in automatic signals for electric railways. Herbert John Haddan, 18, Buckingham-street, Strand, London. (The Storm Railway Signal Company, United States.) (Complete specification.)

9899. Improvements in apparatus for making aerated beverages and automatically and electrically controlling the gas pressure therein. Peter Engelbrecht Malmstrom, 19, Holborn-viaduct, London. (Complete specification.)

APRIL 30.

9947. Improvements in an electric low-water alarm. Charles Arthur Allison, 52, Chancery-lane, London. (Alfred Graham, United States.) (Complete specification.)

9949. Improved means and apparatus for effecting telephonic intercommunication. John Young, 21, Finsbury-pavement, London.

9956. Improvements relating to telephone receivers, audiphones, and the like. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Akouphone Manufacturing Company, United States.) (Complete specification.)

9977. Improvements in pole-pieces for dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Alexander Churchward, United States.) (Complete specification.)

9978. Improvements in pole-shoes for dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Alexander Churchward, United States.) (Complete specification.)

9982. Improvements relating to current-collecting devices for electric traction systems. Emilé Bede and Achille Auguste Condamin, 18, Buckingham-street, Strand, London.

MAY 1.

10000. Improvements in electrical resistances. Alfred Herbert Mayes, 40, Walsingham-road, Hove, Sussex.

10008. Improvements in intercommunication telephones. George Edmund Beckett, 73, Ogden-street, Ardwick, Manchester.

10022. Improvements in shuttles employed in connection with electric stop motions or automatic shuttle changing motions of looms for weaving. Robert Slack, 17, St. Ann's-square, Manchester.

10083. A new or improved method for producing electric insulating bodies. Herbert John Haddan, 18, Buckingham-street, Strand, London. (The "Pyrisolith" Isolating Material Manufacturing Company, Limited, Hungary.) (Complete specification.)

10091. An electric appliance for stopping clocks and giving an alarm. John Shirton and Herbert Yeates, 20, Lower Chestnut-street, Worcester.

MAY 2.

10097. Improvements in conduits for electric mains and in the jointing of same. Leonard Barlow and James Young, 8, London-street, London. (Complete specification.)

10098. Improvements in starting switches for electric motors. Thomas Edgar Weaver, 35, King Edward's-road, Moseley, Birmingham.

10137. A shade or reflector for electric lighting. James Bates Goodwin, 103, Uxbridge-road, London.

10141. Improvements in or relating to electrically-operated switch locking and operating devices, particularly applicable for railway and like purposes. Friedrich Prochaska, 111, Hatton-garden, London. (Complete specification.)

10144. Improved fuseholder for electric current. John Joseph Rawlings, William Robert Rawlings, and Rawlings Bros., Limited, 61, Carey-street, Lincoln's-inn, London.

10181. Improvements in syntonic space telegraphy. Oliver Joseph Lodge and Alexander Muirhead, 323, High Holborn, London.

10185. Means for removing moisture from electric conductor conduits. Isaac Shone and Edwin Ault, 77, Chancery-lane, London.

10189. Improvements in and relating to electric incandescent lamps and to means for connecting the same in the electric circuit. Arthur Llewelyn Lean, 5, Woodsley-terrace, Clarendon-road, Leeds.

MAY 3.

10193. Improvements in collectors for use in connection with overhead electric traction systems. Henry Peace, 24, Temple-row, Birmingham.

10204. Improvements in electrodes. James Hargreaves, John William Stubbs, and John Kearsley, May Villa, Farnworth-within-Widnes.

10206. Improvements relating to electrical fire-alarms and other electrical signalling systems, telegraphy, telephony, wireless telegraphy, and the like. Egerton Goulden Pulford, 10, St. George's-crescent, Liverpool.

10231. Improvements in and relating to high-speed electrical generators and motors. Sebastian Ziani de Ferranti, 18, Southampton-buildings, Chancery-lane, London.

10245. Improvements in receivers suitable for wireless telegraphy. Guglielmo Marconi and Marconi's Wireless Telegraph Company, Limited, 24, Southampton-buildings, Chancery-lane, London.

10246. Improvements in receivers suitable for wireless telegraphy. Guglielmo Marconi and Marconi's Wireless Telegraph Company, Limited, 24, Southampton-buildings, Chancery-lane, London.

10262. Improvements in and relating to arrangements for controlling automatic electric regulators, cell switches, and the like. William Edward Evans, 27, Chancery-lane, London. (Allgemeine Elektricitäts-Gesellschaft, Germany.) (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published May 22.

1901.

6615. Arc lamps. Bremer.

9284. Electrical instruments for signalling on railways. Tyer, Hollins, and Leake.

10188. Electric indicators for use in sectional telephone circuits. Jacobs.

10655. Electrolytic cells or apparatus. Bell and Bell.

10793. Electric indicators. Polyblank.

11242. Electrical primers. Sir W. G. Armstrong, Whitworth, and Co., Limited, and Stuart.

12134. Electric arc lamps and electrodes therefor. Lee.

12342. Electromagnetic winding mechanism for clocks. Schäffer.

13159. Resistance switches and automatic cut-outs for starting, protecting, and regulating electric motors and their circuits. Edmondson.

14751. Process of electrometallurgic treatment of ores of copper and other metals with depolarised insoluble anodes. Tossizza.

15242. Automatic self-righting motion for swivelling trolley wheels on electric tramcars. Birkby and Birkby.

17039. Rifle range telephones. Crosse.

1902.

2820. Apparatus for the electrolysis of water. Garuti and Pompili.

4522. Electric ignition apparatus for internal-combustion engines. Apple.

4906. Controllers for electric vehicles. Simpson.

5851. Prepayment gas or other fluid or electricity supply controlling apparatus. Cooney.

6060. Apparatus for producing high electrical potentials and means for utilising the same for the ignition of explosive mixtures or compounds in explosion motors. Eisemann.

Digitized by Google

6209. Electric arc lamps. Johnson.

6310. Electrolytic separation of metals. Thompson. (Ulke.)

7169. Electric battery. Allison. (Banks.)

Supplement to "The Electrical Engineer,"

MAY 9, 1902.

LONG-DISTANCE TELEGRAPHY AND MARCONI'S LATEST EXPERIMENTS.

BY LIEUTENANT FERNAND PONCELET.

(*Concluded from page 588.*)

M. Guarini has experimented with another kind of antennæ. After his experiments described in the

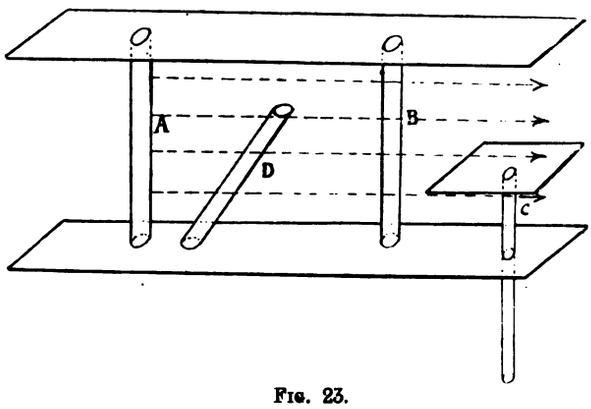

FIG. 23.

Electrical Engineer of July 12 and 19, 1901, he has arrived at this conclusion (British patent, No. 1,555, of

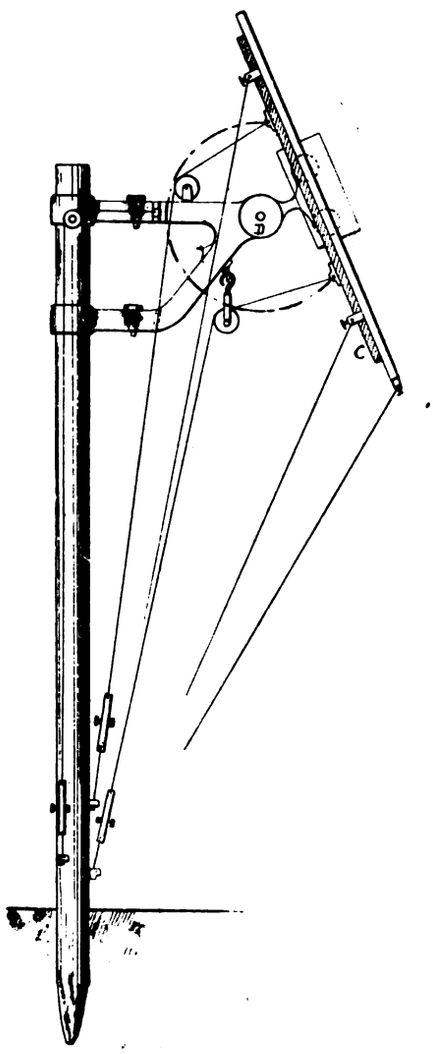

FIG. 24.

Jan. 24, 1900): The best effect is obtained by the use of two equal and cylindrical antennæ placed parallel and at the same height. Such is the case of the two antennæ, A and B, of Fig. 23. An inspection of this figure suffices to show why the antennæ C and D, equal in length to antennæ B, but placed at a different height or not parallel, receive less effect from the radiating antennæ A. A practical way to realise this conclusion can be seen in Figs. 24, 25, 26, 27, and 28 (Belgian patent No. 152,072, of Sept. 14, 1900, entered at the same time in the United

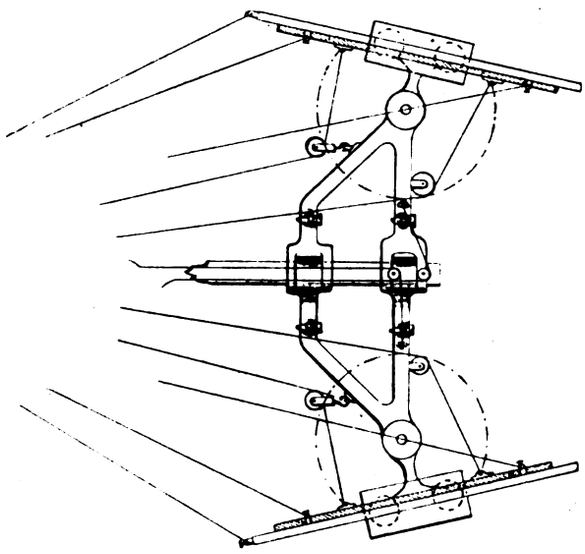

FIG. 25.

States, in Austria, Germany, etc.). Considering Fig. 24, we observe a post supporting at a convenient height two ends of radiating antennæ, A, and collecting antennæ, B, (Fig. 27) parallel to each other, and carried by an isolating plate, C. The oscillator, O, itself is placed on this plate. The antennæ are surrounded by a covering stuck to the insulating material (see the cut in Fig. 26), and in which a longitudinal slit has been made. The plate, C, carrying the two antennæ is susceptible of a rotation in two direc-

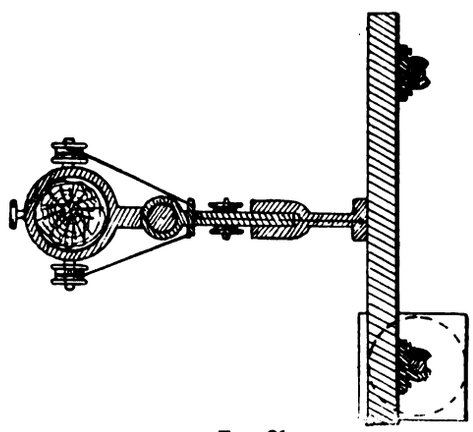

FIG. 26.

tions round the mast to allow a convenient orientation, and round the horizontal axis, D (Fig. 24) to give the required inclination on the vertical. The regulating of the distance between the balls and the oscillator (Fig. 28), and also of two rotations, is effected at the base itself of the mast; conductors join the antennæ to the generating or receiving apparatus placed in an adjoining shed. A transmission station, T, having to communicate with a receiving station, R, the plates, C (Fig. 27), are first placed so as they face each other from one station to the other; they are then inclined on the vertical by rotating them round the post D, so as to render their planes parallel; finally, they are lowered

Digitized by Google

or pulled up along the mast, so that they shall be at the same height. The antennæ A (Fig. 27) of post T will influence the antennæ B of post R, and, to reply to the message, the antennæ A of this latter post will influence the antennæ B of post T. Fig. 25 relates to an intermediary post; the independence of the two plates will be

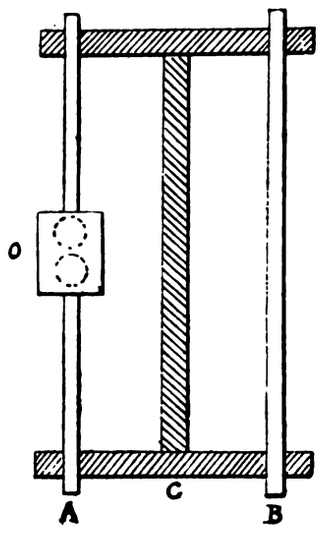

Fig. 27.

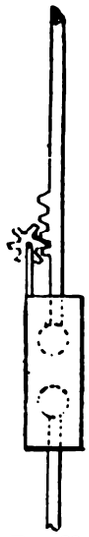

Fig. 28.

noticed. This is necessary to obtain a parallelism of the confronting antennæ all along the line. This arrangement might also be applied advantageously under water in the case of two submarine stations (Fig. 22).

Another way exists to save expense in the energy employed; therefore, to increase the carrying power of the transmission—that is, to seek the aid of flat surfaces

Fig. 29.

for the antennæ (M. Guarini's British patent No. 1,555, 1900). It is based on the following remark (M. Guarini's Belgian patent of June 24, 1899): the electromagnetic waves propagate in space in straight lines normal to the surface of the radiating wire; it is evident that the propagating rays will be parallel if this surface is flat. Fig. 29 shows a few sections of antennæ to meet this condition. In considering, for example, the case of antennæ of square

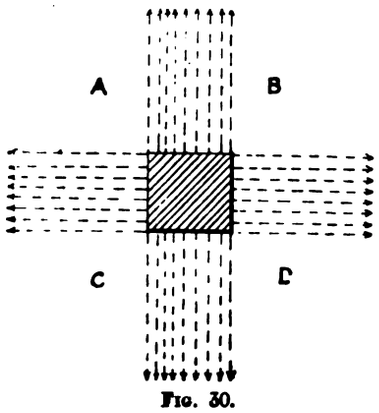

Fig. 30.

section (Figs. 30 and 31), we see that the energy only distributed in the guise of four series of radiations, when the antennæ is provided with the Guarini sheath (see the theory in *Electrical Engineer* of July 12, 1901). In Figs. 34 and 35 the insulating material is taken off so as to show better what happens respectively in the case of the Hertzian current or of high frequency (open-circuit antennæ), and in the case of alternating current or of low frequency (closed-circuit antennæ). It is evident that the radiating and collecting antennæ must then be correctly oriented, so that their uncovered face be well opposite to one another (Fig. 36). One can see on Fig. 7 how M. Guarini applies his system in the case of wireless trans-

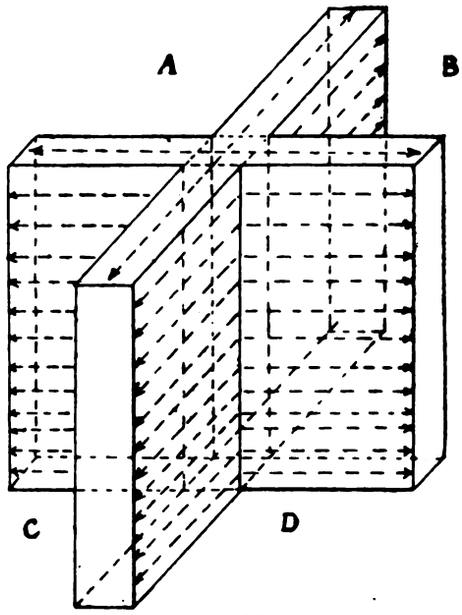

Fig. 31.

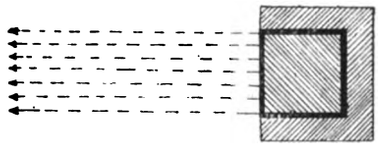

Fig. 32.

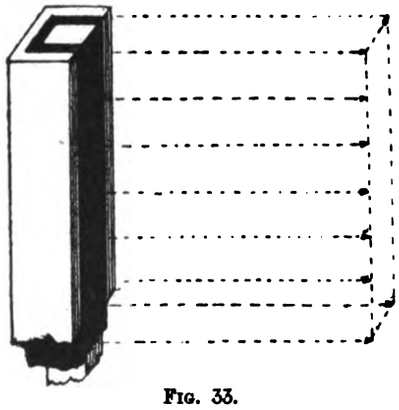

Fig. 33.

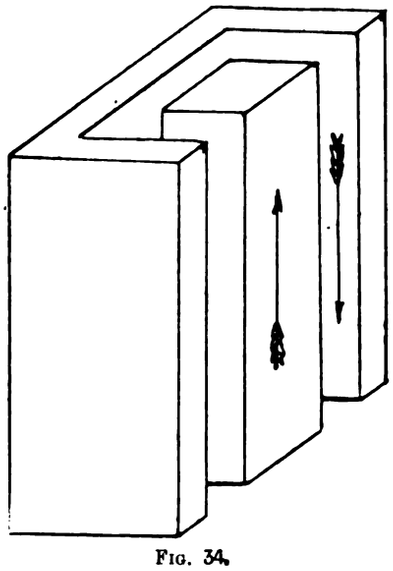

Fig. 34.

mission by alternating currents. This figure relates to the antennæ of circular section, and the insulating material is taken off so as to better show the connections.

Digitized by Google

It is superfluous to add that the above-described Guarini apparatus are practically only applicable to fixed stations, as they require most minute regulating.

V.

Other systems still exist allowing to increase the importance of the transmission. We refer to the syntonisation systems of Messrs. Lodge and Muirhead, Blondel, Marconi, and Slaby. We know that the object of syntonisation is to obtain an electric signal in a predetermined receiving circuit for a given vibrating frequency and not for others. Messrs. Lodge and Muirhead are trying to

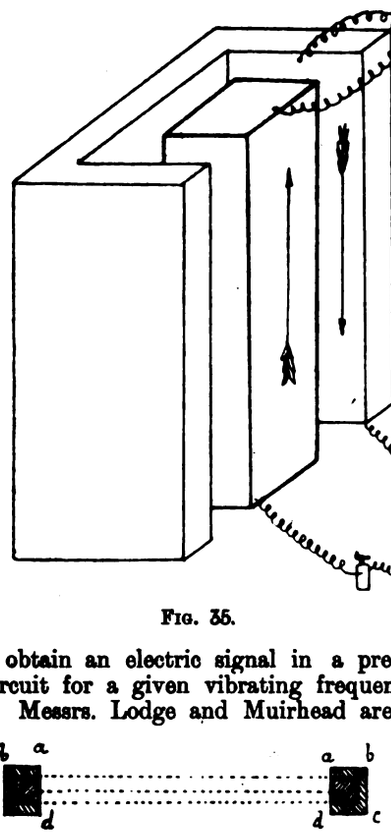

FIG. 35.

FIG. 36.

attain this by working on the self-inductance, L', and the capacity, C', of the receiving circuit so as to obtain the following equality in the oscillating periods:

$$T' = 2\pi\sqrt{L'C'} = T = 2\pi\sqrt{LC},$$

in which L and C belong to the transmitting circuit.

coherence of a coherer, as being "the electromotive power which continually applied prevent the tube from decohering sharply when agitated." They have found that, to be sensitive, a coherer must have a lower critical tension to the electromotive power generated by the waves. This is how M. Slaby utilises this property. At the spot, b (Fig. 38), where the collecting antennæ, $a\,b$, is put to earth, it unites two "extension wires," $b\,c = a\,b$ and $b\,d = \frac{a\,b}{2}$. If we produce two waves at the transmitter, the wave length of one of which equals $4\,a\,b = 4\,b\,c = 8^{bd}$, and the other is equal to $2\,a\,b = 2\,b\,c = 4\,b\,d$, we obtain respectively

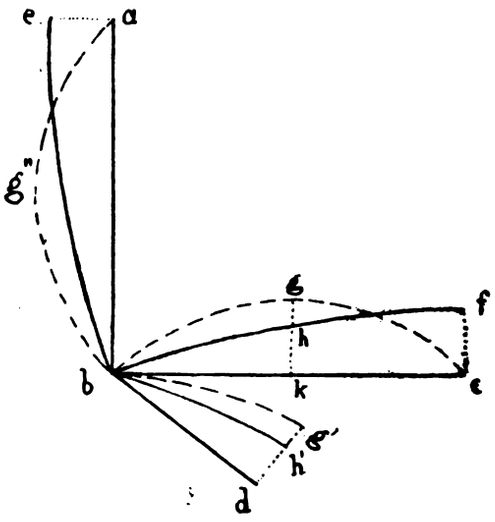

FIG. 38.

the tension curves, $e\,b$, $b\,f$, $b\,h'$, and $a\,g\,b$, $b\,g\,c$, $b\,h$. At the points c and d are placed two coherers, the critical tension of which, t, satisfies the relation: $g\,k\ (= d\,g') > t > h\,k\ (= h'\,d)$. We see that the coherer c will only be influenced by the wave the length of which equals $4\,a\,b$, and the coherer d by the wave the length of which equals $2\,a\,b$. The Slaby receiver, therefore, allows the receiving simultaneously two waves of different lengths—that is to say, two different messages ("Théorie Guarini," Paris *Electricien*, Jan. 18, 1902).

Marconi connects the antennæ to the earth through a transformer primary, of which the secondary meets a condenser and a coherer (Fig. 39). This condenser is for diminishing the tension at the pole of the secondary to which it is attached; the larger the condenser sooner will

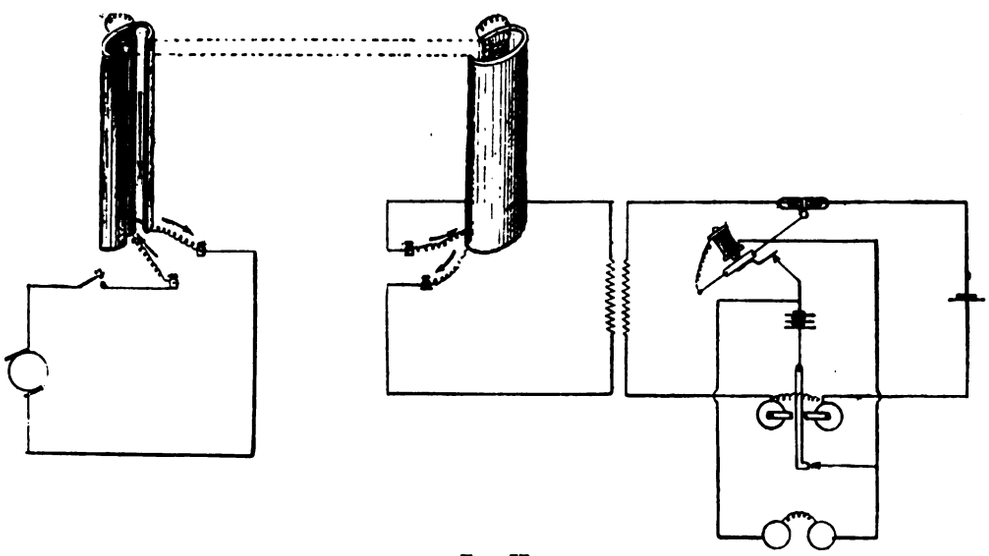

FIG. 37.

M. Blondel adjusts the frequency of the antennæ and that of a special selected receiver. We will here only mention the Marconi and Slaby systems, which result from the Lodge-Muirhead system, and they only have been subjected to numerous experiments. In a note presented to the Paris Academy of Sciences on April 23, 1900, MM. Blondel and Dollkeirtch have defined the critical tension of the tension be annulled, and at the limit—that is to say, when the condenser has the capacity of the earth—we obtain at this pole a node in the wave. The condenser, therefore, here plays the part of the earth connection, b (Fig. 38), of Slaby's system. According to M. Guarini (see the *Electricien*, Jan. 18, 1902), we also know that Marconi takes the length of his transformer secondary equal to the

Digitized by Google

length of the antennæ. Therefore, we find ourselves in the conditions of Slaby's system, and the curves of tension of Fig. 38 can be applied to Fig. 39. The explanation to its working is the same. Fig. 40 represents a second coherer, which plays the part of coherer *d* of Fig. 38. M. Guarini replaces Marconi's condenser of Figs. 39 and 40 by the earth itself (Fig. 41). He is, therefore, in better conditions than Marconi, as the capacity of the earth is infinite compared to that of the condenser. In the Brussels-Malines-Antwerp experiments this system has been tried, and has given good results.

As to the secrecy of the messages that the syntonisation systems would afford, we do not believe in them. Referring to Fig. 38, we see that it is only required to sufficiently

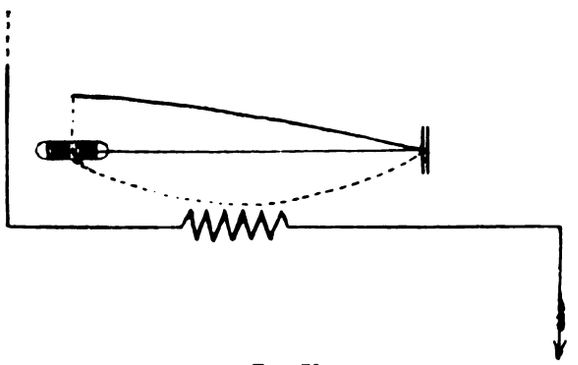

Fig. 39.

lengthen the extension wire, *b c* (the secondary in the transformers of the Marconi and Guarini systems), and to bring from *b* to *c* a coherer of low critical tension to obtain a receiver capable of receiving all the lengths of waves, therefore, to intercept all the messages. On the other hand, the Hertzian refractors are impracticable; similarly the reflectors. The lengths of waves actually in use would much exaggerate the dimension—in fact, we know that one must not place the reflectors at a distance to the antennæ equal to an uneven number a quarter of the wave-length. We only know of one solution of the secrecy to the messages problem—that is, the application of sheaths and flat surfaces advocated by M. Guarini, and which we mentioned in last chapter. We will, however, choose amongst the sections of antennæ, and will reject the circular section antennæ on account of its inconvenience. Fig. 42 shows that if the sheath, *b*, of the antennæ, *a*, subtracts the antennæ A B from all the wave power directed against the antennæ C; on the other hand, the antennæ, D, placed in the series of radiations are influenced. This defect is reduced to the point of being quite negligible if the faces, instead of widening as on Fig. 42, keep a constant size—

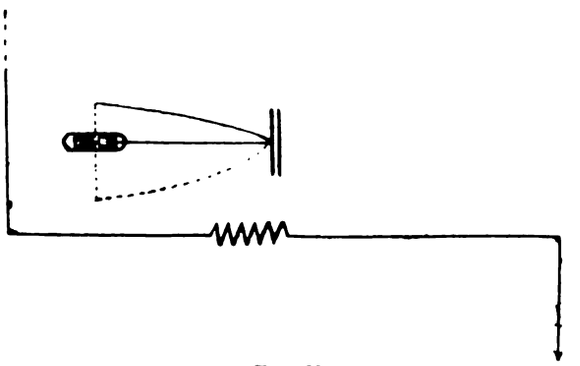

Fig. 40.

that is to say, if the antennæ *a* had a polygonal section. One may say that secrecy is absolute with the antennæ provided with sheaths of polygonal section, as not only the message cannot be intercepted, but it is impossible to blurr the communication, the faces, *a b*, *b c*, *c d*, of the sheaths (Fig. 36) allowing all the radiations which reach it to run to earth. Secrecy of messages can only therefore be obtained by the Guarini antennæ, and syntonisation cannot give it; at the utmost, it can be used for communication between shifting stations in view of increasing the length of transmission.

VI.

For the future of long-distance wireless telegraphy there is another important item to be considered. It is the speed of communication, which greatly influences the cost of messages. We have just seen that syntonisation allows multiplex transmission one way only; it is possible to receive simultaneously as many messages in one receiver than it comprises coherers joined to extension wires (Slaby system) or at secondary transformers (Marconi and Guarini systems) of different lengths. We will not

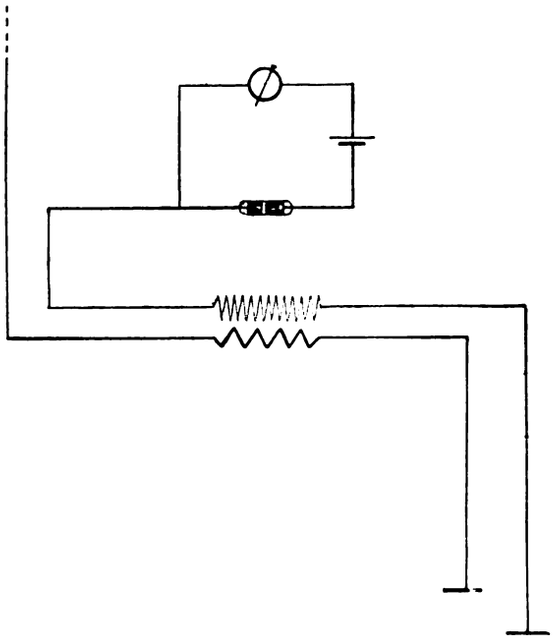

Fig. 41

enter into the details of improvements that one can bring to these systems in view of rendering multi-communication more complete, and we will only remark that the antennæ with polygonal section sheaths permit a multiplex communication both ways. To ascertain this, it is sufficient for one to refer to Figs. 24 and 27, and to imagine that the antennæ of these apparatus are of polygonal sheath and section.

Conclusions.

As the effects of atmospheric electricity can be annihilated to a great extent, chiefly by earthing direct the receiving

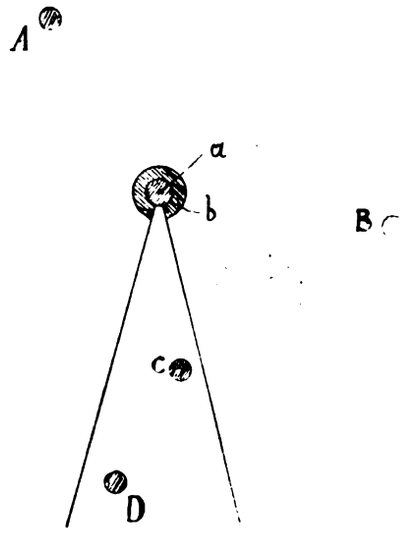

Fig. 42.

antennæ; that the apparatus now in use can be greatly simplified; the power necessary diminished, thanks to Guarini's automatic repeater, to his sheath antennæ, to syntonisation; that multiplex communication is possible one way with syntonised apparatus, and both ways with the Guarini antennæ, it is permissible to think of the future of wireless telegraphy over the ocean. When the improvements which we have mentioned will be facts, the

Digitized by Google

new telegraphy will happily supplement submarine cables. Then it will take its place, as it is by far more economical, and we shall see the cable companies transform themselves into wireless transoceanic telegraph companies, and pay larger dividends to their shareholders. The wireless telegraphy operators will then recall and repeat with more conviction the victorious roar of Marconi: "That day (Dec. 12, 1901) I received from England the message which marks the death warrant of the submarine cables."

THE DISTRIBUTION OF MAGNETIC FLUX IN LARGE ELECTROMAGNETS.*

BY W. M. THORNTON, M.SC. (MEMBER).

(Concluded from page 592.)

§ 6. Permeability of Iron in Bulk.

Attempts have been made from time to time to measure the permeability of iron when in bulk. Even when the highest skill has been given to design, there are often unexplained discrepancies between calculation and performance in large machines. These are attributed when every other explanation fails, to the iron not being to sample. The method of manufacture of the frames must affect the magnetic properties, as, for example, the cooling of large castings too quickly, and the consequent hardening of the metal, reducing the permeability. The following method, which follows from the former part of the paper, may be used on any large magnetic circuit, whether that of a generator or motor, and with faster recording apparatus for transformers. Any large masses of metal of convenient shape on which coils may be placed can be so tested. In the case of machines, it is only necessary to know the exact dimensions of the various parts, though when in course of construction the influence of the air-gap may be avoided by using an armature of soft iron of known permeability fitted across the flat ends of the magnet cores, clamped to the yoke, and with a current passed round experimental coils in the ordinary way. The exploring coil may be placed round the yoke or core, and induced voltage curves taken as described. In practice it is possible to take a complete cycle of a large machine, including the development of the photographs, in less than an hour.

Plate IX.

Plate IX. gives the first set of curves with varied current taken with the Holmes machine, and from these the following values of B are found and of μ for the whole machine.

Table VIX.

Amperes.	Amp.-turns per cm.	Amp.-turns per inch.	H., C.G.S.	Area of diagram, sq. cm.	Flux.	B per sq. cm.	B per sq. inch.	μ per sq. cm.	μ per sq. inch.
·6	5·15	12·95	6·42	2·58	$8·96 \times 10^5$	692·5	4,460	107·8	272
3·35	28·79	70	35·95	22·12	$7·68 \times 10^6$	5,925	38,250	165	418
5·83	50·1	126·3	62·75	35·93	12·47 ,,	9,615	62,100	153·3	389
8·3	71·25	179·8	89·25	50·4	17·5 ,,	13,500	87,100	151·3	384
10·8	92·75	233·7	116·2	56·3	19·6 ,,	15,100	96,800	84	214·5

The total reluctance, R, is the sum of the terms $\frac{l}{A\mu}$ for each part where there is a variation of material or dimensions.

$$R = \frac{l_g}{A_g} + \frac{l_a}{\mu_a A_a} + \frac{l_y}{A_y \mu_y} + \frac{l_c}{A_c \mu_c} + \frac{l_p}{A_p \mu_p},$$

g, a, y, c, p referring to gap, armature, yoke, cores, and poles respectively. For any part of the circuit the flux is the ratio of the magnetomotive force required for that part of its reluctance. Thus the ampere-turns for the gap $= ·8\ N_g \frac{l_g}{A_g}$, and there are similar terms for the other parts.

The total ampere-hours $I T = ·8 \Sigma \left(\frac{N_g l_g}{A \mu}\right)$ or $= ·8\ \Sigma\ (N R)$.

The reluctance of the gap is known from its dimensions. The permeability of the armature for soft iron is given by the makers, and since the yokes, poles, and core are generally of the same material,

$$I T = ·8\left(N_g \frac{l_g}{A_g} + N_a \frac{l_a}{A_a \mu_a}\right) = \frac{·8}{\mu_c}\left(N_y \frac{l_y}{A_y} + N_p \frac{l_p}{A_p} + N_c \frac{l_c}{A_c}\right).$$

Let the ratio $l/A = k$, a constant for each part, then

$$I T = ·8\left(N_g k_g + \frac{N_a k_a}{\mu_a}\right) = \frac{·8}{\mu_c}\left(N_y k_y + N_p k_p + N_c k_c\right).$$

The left-hand side of the equation is known for any value of the magnetising current, and by means of a set of curves, as, for example, Plate IX., the fluxes, N, for all the parts are known. Thus

$$\mu_c = \frac{·8\,(N_y k_y + N_p k_p + N_c k_c)}{I T - ·8\left(N_g k_g + \frac{N_a k_a}{\mu_a}\right)}.$$

For different saturations the proportions between the various N's are not constant, and although one set of curves is sufficient to give the required value of μ under ordinary working conditions, yet the whole range of μ may be found by taking several sets of curves, one for each change in the magnetising current. Having determined the absolute flux through the armature, which may be done either by standardising the galvanometer or running the machine at a given speed on open circuit, and measuring the voltage, the value of μ can be expressed in terms of the relative areas of the curves—*e.g.*, in Plate III.

Write λ the ratio of the area of any curve to that of the armature curve. Then

$$\mu_c = \frac{·8\ N_a\,(k_y \lambda_g + k_p \lambda_p + k_c \lambda_c)}{I T - ·8\ N_a\left(k_g \lambda_g + \frac{k_a}{\mu_a}\right)}.$$

The second term in the lower bracket may generally be neglected by reason of the high value of μ_a.

For the Castle dynamo I = 10·75, T = 2,393, and from the dimensions

$k_g = ·069$; also $\lambda_y = 1·15$.
$k_p = ·06$ $\lambda_p = 1·2$.
$k_c = ·058$ $\lambda_c = 1·4$.
$k_g = ·00177$ $\lambda_g = ·91$.
$k_a = ·025$.

$$\text{Hence } \mu_c = \frac{·8 \times 14 \times 10^6\ (·069 \times 1·15 + ·06 \times 1·2 + ·058 \times 1·4)}{25{,}700 - ·8 \times 14 \times 10^6\left(·00177 \times ·91 + \frac{·025}{500}\right)}.$$

That is, $\mu_c = 371$.

The flux density is 15,100, and the above value may be compared with 219 (Witten), 423 (Fisher, Schaffhausen), and 580 (Plichon, Paris), found by Fisher-Hinnen for cast steel at the same flux density. The above is for Armstrong-Whitworth steel.

In the case of the Parker machine of § 5, the total ampere-turns were 53,500 distributed equally between the two bobbins, and there were no compounding turns. Also

$k_y = ·0812$; and $\lambda_y = 1·255$.
$k_c = ·1034$ $\lambda_c = 1·32$.
$k_p = ·1430$ $\lambda_p = 1·2$.
$k_g = ·00271$ $\lambda_g = ·915$.
$k_a = ·025$

The armature flux is $30·7 \times 10^6$ lines ; thu

$$\mu_c = \frac{·8 \times 30·7 \times 10^6\ (·081 \times 1·255 + ·1034 \times 1·32 + ·143 \times 1·2)}{53{,}500 - ·8 \times 30·7 \times 10^6\ (·00271 \times ·915 + ·025/500)}.$$

Hence $\mu_c = 358$.

Wiener's value for annealed wrought iron at the same flux density is 333.

The Silvertown machine has 49,500 ampere-turns, and

$k_y = ·1255$; also $\lambda_y = 1·145$.
$k_c = ·1125$ $\lambda_c = 1·29$.
$k_p = ·108$ $\lambda_p = 1·15$.
$k_g = ·00187$ $\lambda_y = ·84$.
$k_a = ·06$

The armature flux is $32·1 \times 10^6$ lines, corresponding to a flux density in the gap of 6,200 per square centimetre. Thus

$$\mu_c = \frac{·8 \times 32·1 \times 10^6\ (·1255 \times 1·145 + ·1125 \times 1·29 + ·108 \times 1·15)}{49{,}500 - ·8 \times 32·1 \times 10^6\ (·00062 + ·0001)}$$

That is, $\mu_c = 347$. With B = 15,100.

Wiener's corresponding value is 343.

The same formula applies to multipolar circuits. Measurements of the Brown-Boveri generator give the following data :

$N_y = 7·5 \times 10^6$; and $k_y = ·525$.
$N_p = 14·4$,, $k_p = ·0044$.
$N_c = 17·1$,, $k_c = ·074$.
$N_g = 14·4$,, $k_g = ·0035$, with $l_g = 1''$.
$N_a = 7·2$,, $k_a = ·37$.

The value of k_g was obtained on the assumption that the effective air-gap was 1", taking into account the reluctance of the teeth, which were not included in k_a. The ampere-turns per pole were found from the winding space to be 20,800, and in the absence of the maker's figures this is only an approximation. With these values :

$$\mu_c = \frac{·313\ (7·5 \times ·525 + 14·4 \times ·0044 + 17·1 \times ·074)\ 10^6}{20{,}800 - ·8 \times 10^6\ (·0198 + ·00228)}.$$

Thus $\mu_c = 670$, the average for core, yoke, and pole ; the flux density in the cores being 13,000 and in the yoke 11,000 lines per square centimetre. Wiener's value for cast steel at 12,400 is 740 ; Fisher-Hinnen for Fisher of Schaffhausen steel gives 750.

* Abstract of paper read before the Newcastle Local Section of the Institution of Electrical Engineers, March 24.

§ 7. Application of Heaviside's Theory of the Decay of Induction in Cores.

Lamb and Heaviside have discussed the changes which take place in a solid conducting core when the coil circuit is interrupted or short-circuited. Using Heaviside's notation (Heaviside's "Electrical Papers," vol. i.), let H be the intensity of magnetising force at any instant at a distance r from the axis of the circular core.

Then
$$H = \frac{2 H_0 J_0 (n r) e^{D t}}{n c J_1 (n c) (1 + S^2 n^2)} \quad . \quad . \quad . \quad . \quad . \quad . \quad (i.)$$

where H_0 is the constant magnetising force due to the steady current in the coil when normally excited, c the radius of the core, and $S = \frac{L \rho}{2 \pi \mu c R}$, in which L is the inductance and R the resistance of the coil, ρ the specific resistance, and μ the average permeability of the core. Also $D = -\frac{n^2 \rho}{4 \pi \mu}$, n being the first root of the equation $J_0 (n c) = S n J_1 (n c)$, where J is a Bessel function of the order indicated.

Heaviside has given the roots when S and $c = 1$—that is, for a very small core. For one 20·32cm. radius, the results are best obtained by taking $c = 2{\cdot}032$ decimetres, changing the corresponding values of H_0, S, and μ, and solving by trial. Written fully, the equation is

$$1 - \frac{c n^2}{2}\left(\frac{c}{2} + S\right) + \frac{c^3 n^4}{16}\left(\frac{c}{4} + S\right) - \frac{c^5 n^6}{384}\left(\frac{c}{6} + S\right) \quad . \quad . \quad . \quad = 0.$$

The form of solution by successive equations does not lead to any definite result, but by trial and error, using the values of $J (n c)$ and $J_1 (n c)$, in Gray and Matthews's "Bessel Functions," it is found that with $(n c) = {\cdot}4$ the right-hand side is ·99, while $J_0 ({\cdot}4) = {\cdot}9603$, and with $(n c) = {\cdot}39$ the respective values are ·94 and ·9623. By interpolation, $(n c)$ corresponding to a root is ·3942.

Thus
$$n = \frac{{\cdot}3942}{2{\cdot}03} = {\cdot}1958.$$

Hence
$$D = -\frac{{\cdot}0384 \times 10^4}{12{\cdot}56 \times 158{\cdot}5} = {\cdot}1928.$$

Since $\bar{\mu}$ was found to be 158·5. This may be compared with the value actually found from the make curves—*i.e.*, ·185. The calculated value of D is on the assumption that the magnetic circuit is a closed ring of iron of circular cross-section, uniform along its length. The actual machine has sections of different shapes, circular in the windings' core, which is the most important part, rectangular in the poles and armature, and D-shaped in the yoke. Under these conditions the agreement may be considered close.

The whole flux N can be found from (i) thus. At any point

$$B = \mu H,$$
$$= \frac{2 \mu H_0 J_0 (n r) e^{D t}}{n c J_1 (n c) (1 + S^2 n^2)},$$

and
$$N = A B \bar{H},$$

where $\bar{H}$ is the average value of H over the core at time t. Then

$$N = \frac{2 A \mu H_0 e^{D t}}{n c^2 (1 + S^2 n^2)} \frac{1}{J_1} (n a) \int_0^c J_0 (n r)\, dr.$$

and
$$\int_0^c J_0 (n r) = c\left(1 - \frac{n^2 c^2}{2^2 3} + \frac{n^4 c^4}{2^2 4^2 5} - \frac{n^6 c^6}{2^2 4^2 6^2 7} + \quad . \quad . \quad .\right)$$

Thus
$$\int_0^{2 \cdot 032} J_0 (n r) = 2{\cdot}005 \text{ to five terms.}$$

And
$$N = \frac{2 \pi}{{\cdot}1958} \cdot \frac{1{,}585 \,.\, 4 \pi i t \times 2{\cdot}005}{[1 + \,.\, (25{\cdot}8 \times {\cdot}1958)^2] \cdot 1915 \times 28{\cdot}4} \cdot e^{-{\cdot}1928 t}$$

For in decimetre units
$$\mu = 1{,}585$$
$$l = 28{\cdot}4 \text{ decimetres.}$$
$$S = 25{\cdot}8.$$

Thus
$$N = 22{\cdot}9 \times 10^6 e^{-{\cdot}1928 t}.$$

The maximum value for the machine as found by test is

$$N = 20{\cdot}25 \times 10^6 e^{-{\cdot}185 t}.$$

It would be difficult to obtain an experimental verification of the theory except by tests on a massive non-magnetic anchor ring of high conductivity. The above value shows that even under very unfavourable conditions a fair agreement is found.

In making tests on machines with elliptical or rectangular cores, the eddy currents at make or short-circuit must follow the shape of the periphery as a limit. The distribution of magnetisation with space and time in such cases will no doubt be complex, for, especially in rectangular cores, the current density for the same current element changes in the inverse ratio of the radius vector of the circumference at any particular cross-section. The only guide to the distribution is the continuity which there mus be between the various parts of lines of flow in the core. The best conception of the true state is obtained by Prof. Hele Shaw's method of liquid stream lines, and even then these are in the true core distorted by the local variations of permeability with the strength of the magnetic waves. (Prof. Hele Shaw has kindly applied his method to the examination of the eddy-current paths in rectangular cores, the effect of variable permeability being imitated by spacing the entering holes of the flow first equally, then in proportion to the spacing observed at leaving the plate, this being repeated several times, until the change produced by successive alternation is too small to affect the position of the lines of flow. A change in thickness is, in general, the analogue to a change in permeability. The variation of permeability here with time renders some further approximation to the disturbed state necessary, such as the unequal spacing.) An elliptical core will, during the persistence of the eddy currents, have less permeability along the minor axis than the major. The average value might be the arithmetical mean of the two if the waves remained parallel to the boundary. With an alternating impressed force the reflections of the waves from the centre will set up a very intricate distribution in the core, but in the single wave at make or short-circuit the type will be simple until the disturbance is close to the centre.

The average radius vector for an ellipse may be proved to be

$$\bar{r} = \frac{b}{2} + \frac{a}{2e} \sin^{-1} e,$$

where a and b are the semi-axes and e the eccentricity. Thus for a core 80cm. by 50cm. the average is

$$= 12{\cdot}5 + \frac{20}{{\cdot}737} \sin^{-1} {\cdot}737,$$
$$\therefore \bar{r} = 34{\cdot}9\text{cm.}$$

The circle of equal area has a radius of 31·6cm., and whether the rate of decay will follow from this or the mean radius, or some intermediate value, can only be decided by experiment. The circle of equal area will have a greater apparent time-constant than an ellipse, and in the limit when the ellipse is extremely long and narrow the waves from the side will meet in a very short period, and the motion decay according to a logarithmic law. In a rectangular core the same effect takes place, the circle of equal area having the greatest possible time constant that the magnetism could possess, and a long flat rectangle—*i.e.*, a transformer plate, having no eddy-current circulation which can be directly observed. The equivalent circle has a radius $= 1{\cdot}128 \sqrt{ab}$. Lamb's and Heaviside's theory might be extended to these cases by considering the motion as one of flow of a viscous fluid in a prism round the axis, the viscosity varying with time according to some approximation to the curve of permeability.

From the tests on the Silvertown and Parker machines the time-constant may be approximately found and the equivalent circular core calculated.

Since $\frac{1}{D} = \frac{4 \pi \mu}{\rho n^2}$, and $n^2 = \frac{5{\cdot}783}{a^2}$ for the first root, then

$$a^2 = \frac{\rho \times 5{\cdot}783}{4 \pi \mu D};$$

$$a^2 = {\cdot}46 \frac{\rho}{\mu D} \text{ square centimetres.}$$

An assumption has to be made for ρ; μ can be found from the values of the time constant obtained from Plates XIV. and XV.

The average permeability was found by calculating the reluctance from the flux and ampere-turns for $R = \frac{\text{M.M.F.}}{N}$, and taking the average of the constants $k = \frac{l}{A}$. Then $\frac{\bar{k}}{R} = \bar{\mu}$.

Taking an average of 58, and $\rho = 10^4$, with D = 192 as found from the curve of make, $a^2 = 412$. Therefore $a = 21{\cdot}5$cm., or = 8·47in.

The core is 26½in. × 16in. = 424 square inches area, and the radius of the circle of equivalent area is 11·62in. Thus, according to the above figures, based on the assumption that there is a harmonic distribution of magnetism on the core, of which only the first root is important, the circle of equivalent decay is less than the smallest side of the rectangle.

In the case of the Parker machine with the same value of ρ, reluctance ·00132, $\bar{k} = {\cdot}08$. $\bar{\mu} = 60{\cdot}5$.

$$a^2 = \frac{10^4 \times 5{\cdot}783 \times 7{\cdot}3}{12{\cdot}56 \times 60{\cdot}5} = 555.$$

Hence $a = 23{\cdot}28$cm. = 9·29in. radius of equivalent circle.

The least radius of the rectangle is 7½in., the greatest 14in., and the circle of equal area is 11·4in. radius.

§ 8. Further Study of Leakage.

From Plates I. and II. it is seen that the leakage from the lower half of the left-hand bobbin, the surface of the pole not including the gap, and the bottom of the left-hand pole are respectively ·14, ·126, and ·101 of the armature flux. That is a total of 1·367 accounted for, as against 1·4 observed directly. A portion of the leakage was, however, inadvertently omitted, from the edges of the poles above and below the armature, and though some of this passes into the armature, yet the remaining ·033 might well be accounted for at these points.

Table X.	Reluctances.
Magnet core	·000156
Yoke	·00015
Poles	·00015
Air-gaps	·00177
Armature	·000059
Total in series	·002285

The closeness of the above agreement suggested that the reluctance of the leakage paths might be directly observed, and, if desired, the formulæ in text-books of design checked. The distribution is, however, so complex on account of the current surfaces of the Castle dynamo that it does not permit of exact comparisons. The Parker and Silvertown machines would be more suitable, having large rectangular surfaces. Between the middle and bottom of the left-hand bobbin of the Holmes machine $1{\cdot}96 \times 10^6$ lines are lost, representing an average surface density of leakage of 4,384 lines per square inch, or nearly one-tenth of that in

Digitized by Google

the gap. The reluctance of the whole circuit, as given by the relation $R = M.M.F./N\phi$, includes all the leakage paths. Since the M.M.F. is 32,350 and the maximum flux 19×10^6, this reluctance is ·0017. That for 14×10^6 lines alone is ·0023, and for the leakage alone ·00578. Taking 370 for the permeability of the core and 500 for the armature at the working flux density we obtain Table X.

The reluctances of the various leakage paths would be known if the magnetomotive forces for each could be determined, the flux being already measured. The total magnetic potential on the circuit is 32,350 C.G.S. units, and the leakage between any two surfaces is proportional to the potential difference between them. The diagram (Fig. 15) shows the general analogy between the leakage distribution and a similar current network. From the reluctances the slope of potential throughout the circuit can be found when the flux for the various sections is known.

Thus, in the left-hand bobbin the M.M.F. = 22,150
in the right-hand it is ..... = 10,200

The total being 32,350

This is distributed as in Table XI.

TABLE XI.

	R × N.		M.M.F.
Left-hand bobbin core	·000078 × 18·5 × 10^6	.....	1,440
,, pole	·000075 × 16·5 ,,	.....	2,350
,, gap	·000885 × 12·7 ,,	.....	11,300
,, armature	·000059 × 14 ,,	.....	826
Right-hand gap	·0000885 × 12·7 ,,	.....	11,300
,, pole	·000075 × 16 ,,	.....	1,200
,, bobbin core ...	·000078 × 18 ,,	.....	1,405
,, yoke	·00015 × 17 ,,	.....	2,540
Total			32,356

These values have been drawn in Plate XXIV., the abscissæ being the respective lengths along the centre line of the machine. Thus the

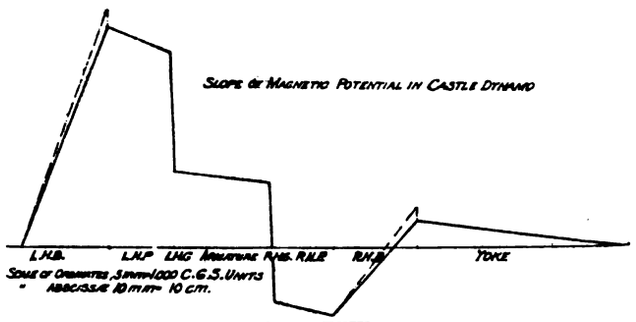

PLATE XXIV.

potential difference between the yoke and the left-hand pole surface is found by, in this case, subtracting the mean height of the yoke line of slope from that of the pole. Its value is thus found to be 17,000 units. The flux from the half yoke upper surface is 435,000 lines. The reluctance of this path is then $\frac{17,000}{435,000} = ·039$. Table XII. gives the values found in this way for the paths measured.

TABLE XII.

Path from	Flux.	M.M.F.	Reluctance.
Yoke to left-hand pole and lower half of bobbins	435,000	17,000	·039
Lower half of left-hand bobbins to yoke and right-hand bobbins	1,960,000	18,800	·0096
Outer surface of left-hand pole to yoke, bed-plate, and opposite pole	1,540,000	26,000	·01685
Bottom of left-hand pole to bed-plate, etc.	1,330,000	25,000	·0188
Bottom of right-hand pole to bed-plate, etc.	1,170,000	25,000	·0214

The same flux is here included in several of the paths, and it is horizontal a little above the centre line of the armature, all above going to yoke and bobbins, below to the bed-plate and opposite pole.

The relative leakage was determined by observing the current required in a coil of 500 turns and mean radius 85cm. to reverse the flux. The action of the coil in the strong leakage field causes a considerable disturbance of the lines, and the results could not be relied on as absolute measurements. For comparative work, however, it appears more reliable than the attracted soft-iron sphere method of exploring the leakage at the surface, and it can be used to find the intensity at any point of the field some distance from the machine. Using Fisher-Hinnen's and Wiener's formulæ for the permeance of simple leakage paths, the values in Table XIII. have been calculated.

TABLE XIII.

Leakage path.	Reluctance.
1. Upper to lower half of bobbins	·0146
2. Between circular cores	·0093
3. From yoke to left-hand pole surface	·12
4. Bottom of poles to bed-plate	·0114
5. Side of poles to bed-plate	·0125
6. Yoke to lower half of left-hand bobbin	·08

From these it is seen by comparison with Table XII. that there is considerable difference between calculated and observed values. All these are for no load, and that the distribution is materially modified by the action of the compounding coils was proved in Section 2. Several of the paths in Table XIII. are taken together in Table XII. Combining them, Table XIV. is obtained.

TABLE XIV.

Table XI.	Calculated.	Observed.
Paths 3 and 6	·048	·039
,, 1 and 2	·0057	·0096
,, 3 and 5	·0113	·0168
4	·0114	L.H. ·0188
—	—	R.H. ·0214

It is desirable that further measurements should be made on machines of simpler contour.

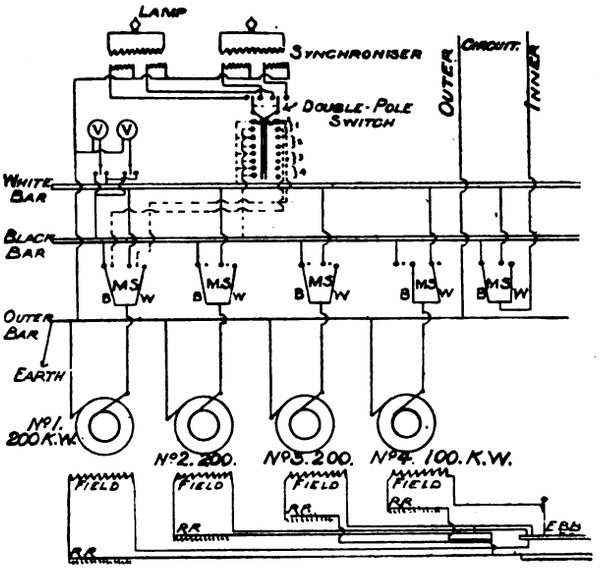
By means of the two methods—using coils surrounding the cores or placed about an area on the surface, and comparing one result with the other—a very complete knowledge of the true distribution of magnetism in and about large electromagnets can be obtained. To carry them out in practice it is only necessary to have a recording ammeter of sufficient dead-beatness and power, or freedom from friction and inertia.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Question No. 472.—Three 200-kw. Siemens alternators, each coupled direct to Willans engines, are running in parallel. Nos. 1 and 2 are fully loaded. A No. 4 set, of 100 kw. capacity, is the only spare machine. The exciters are running in parallel, and supply current to the field windings of alternator from 'bus bars. Please give a practical description of what to do should one of the armature coils start to burn out—say No. 1 alternator. A Ferranti switchboard is used.

Best Answer to No. 472 (*awarded* 10*s.*).—The accompanying sketch is a diagram of connections of a Ferranti switchboard and one form of synchroniser. It will be seen that the outer of each alternator is connected to a common "outer bar," which is "earthed," while the inner of each alternator is connected to a main switch, M S, which being double, enables each machine to be put on either the



"white" or "black" bars. The fields of the machines are connected in parallel through regulating resistances, R R, to the exciter 'bus bars, E B B. The circuits, as shown, can also be put on either the "white" or "black" bars with a common outer. Referring to the question given, Nos. 1, 2, and 3 are supposed to be running fully loaded on the "black" bar with their "black" main switches, B, closed, as shown. The circuit "black" switches are also closed. As soon as it is known that an armature coil of No. 1 is burning out, the first thing to do is to get the spare set, No. 4, started, and run up as fast as possible to the working voltage, say 2,000 volts, on the "white" bar, as shown in sketch. Next, get on to the circuits, pulling off the "black" circuit switches, B, and immediately putting on the "white" switches, W, until No. 4 gets pretty well loaded up to its capacity. This changing of part of the circuits from one bar to another only produces a momentary flicker in the lights, and there is not the chance of a "bad phase," as no synchronising is required so far. No. 1 must be got off as soon as possible, the other machines being overloaded for

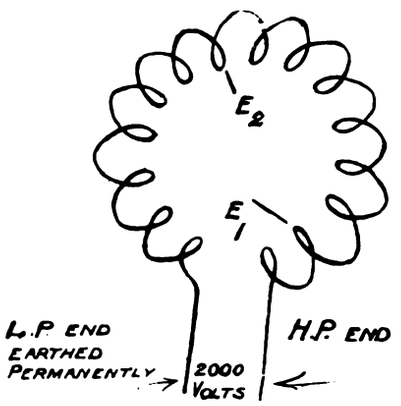
Digitized by Google

the time being. Suppose we have now got No. 1 off and Nos. 2 and 3 overloaded on "black" bar, and No. 4 in the same condition on the "white" bar, it only remains to synchronise the "white" bar with the "black," and when this is successfully accomplished by closing B switch of No. 4 at the right moment, then the B circuit switches may be closed and the W ones pulled off; and we now have Nos. 2, 3, 4 all running overloaded on the "black" bar, while the "white" bar is spare until required again. If this order of events is carried out there is no use of anyone getting excited, as the synchronising can be done at leisure. I have only shown No. 1 machine connected to the synchroniser, but the other machines are connected in precisely the same way. No instruments are shown except synchronising voltmeters, V.—R. S

Answer to No. 472 (*awarded* 5*s.*).—If when running three alternators in parallel the armature of one set starts burning up, the following procedure would have to be gone through: (1) Switch out faulty alternator by pulling out main alternator switch (if there is sufficient time full steam would be put on other sets, and load reduced on faulty set before switching out). (2) Switch out field switch of faulty machine, which cuts off exciting current and prevents unnecessary damage to armature. (3) If exciter of faulty set is paralleled on 'bus bars with other exciters, load will have to be got off this exciter by putting resistance in exciter field and exciter main switch pulled out, and then the faulty set can be shut down. (4) Switching out a fully-loaded set wire naturally causes volts and speed of remaining sets to fall. Full steam (by means of governor wheel and cut-off) will be put on remaining sets, and resistance taken out of field circuits in order to raise the pressure. The excitation must not be increased too much, or it will pull down speed of engines instead of raising pressure. (5) Meanwhile spare set will be run up to speed, and steam pressure on boilers got as high as possible. The spare set running at lowest speed on governor will most probably be running too fast for paralleling with other sets; by nearly closing stop valve, and regulating speed by means of stop valve, it can be got right for paralleling without much difficulty. (6) Machine is then switched in and stop valve opened gradually, and resistance taken out of field circuit, in order to make the set take up its share of the load.

In most cases the above can be successfully done, but if the load on the remaining sets is so great that there is not sufficient pressure to parallel by, one or more feeders will have to be switched over on to the spare set, and machine paralleled with others afterwards. Siemens's alternators will stand shorts and overloads without much risk to the machines, but if the machine fuses are too light they will be liable to go.—H. B. D.

Answer to No. 472 (*awarded* 5*s.*).—(1) We will commence by considering what happens if a coil burns out.



It will not burn long before it puts the machine to earth, and if this coil happens to be at or near the high-pressure end of the armature a dead short occurs around that machine, and it also short-circuits the others. If the machines are fused reasonably 400 kw. should blow a 200-kw. fuse, and thus cut the machine off the 'bus bar. But there is still a short-circuit around that particular machine, which if left long enough will burn the armature out. Therefore, as the governing of a Willans engine is very good, switch off the field and shut the engine down as soon as you can. (2) But if the machine went to earth at, say, E_2 in the figure, the fuse would not blow, but the section of the armature between the earthed end and E_2 would soon burn up. Therefore, dispatch is very essential in order to avoid these things.

"R. H." does not state if his engines are condensing or non-condensing. Let us consider the two cases: (1) *condensing*—the engine will do 25 per cent. overload with 26in. vacuum; (2) *non-condensing*—the engine will do 10 per cent. overload.

The above points should always be tested on the spot. If you are within these limits, let them have it, and put in your spare machine as soon as you can. But if you are not, parallel your spare machine if you can.

The Worst Conditions.—We will now suppose the three 200-kw. machines are fully loaded, and that when trying to parallel your fuse goes: (1) take out your exciter switch and shut down; (2) pull out the machine switch. You are then in a very bad position, your volts are down considerably, and the synchroniser voltmeter will not read. If you have no other instruments—and I *must* take it you have not—a low-reading voltmeter would get you over this difficulty. (1) Ease the load off your engines by decreasing the excitation, getting your driver to cut an equal amount of steam off each. (2) Take out the feeder switches. (3) Parallel the 100-kw. machine on the empty 'bus bar with the two 200-kw. sets. Get the speed and volts high. (4) Put in the feeder switches as near as possible together, and bring up the engines to normal speed. As you are then running at an overload, this may not be possible, but it is the nearest thing possible.—P. A.

Answer to No. 472 (*awarded* 5*s.*).—In a case of this sort quickness on the part of the switchboard attendant is the most essential thing, and to keep a cool head, or else it is 10 to 1 he will shut the station down or do something equally as silly. As soon as he sees what is happening, let him get the machine off the load as quickly as possible and the exciting current broken. If the machine is motoring while the short is on, he should be careful to see that the needle of his ammeter is at zero, as otherwise he will get a destructive arc on breaking contact. If the needle is hard over, lower the exciting current to permit of switching safely. Now, as soon as the machine is out, he will find that the remaining ones are a trifle overloaded, so that if scares him, let him take off some of the circuits that he is feeding (and which can be done without for a short time) while the 100-kw. is being run up to synchronism, and then parallel it. Of course, he will continually have an overload if he puts his circuits on again; but still that shouldn't worry him or the station chief, as I daresay the machines will do it without hurting them so very much.—A. H. E.

Answer to No. 472 (*awarded* 5*s.*).—It is evident from the question that there will be more than a full load for the two big sets alone. However, as coils that burn up have a habit of giving no warning, it would be best to let the machine with the faulty coil rip until you had opened right out on the No. 3 set, then pull No. 1 set's main switch and exciter switch out as near simultaneously as possible, and let the two big sets take the whole of the load until you have paralleled the spare machine. Of course, there will be a certain amount of voltage drop, and most likely some motoring. The latter can soon be stopped, especially if the engines have variable cut-offs (as this size of Willans engine often has), by adjusting the same; or, on the other hand, by taking one of the sets off the governors on to the valve. No doubt No. 4 set would have to be put in on the valve, and as it is more difficult to phase machines on the valve than on the governors, I should advise a flying shot at the first phase up; then, when in, open her out, and if the machines are by this time running steadily, bring the engine which is on the valve on to the governors again, and resume the working conditions. This operation ought not to last more than three minutes.—R. N. T.

Printed and Published for the Proprietors by MESSRS. BIGGS AND CO., at the Offices of "THE ELECTRICAL ENGINEER," 139 and 140, Salisbury Court, Fleet Street, London, E.C.

Digitized by Google

NOTES.

"The Electricals."—A smoking concert arranged by "The Electricals" will be held at the Bedford Head Hotel, Tottenham Court-road, next Friday evening, commencing at 7.30 sharp. Sir David L. Salomons, Bart., will occupy the chair, supported by Mr. C F. Quicke, the vice-president of the club. An excellent programme is promised, and a large attendance of members and friends is looked for.

Royal Institution.—On Tuesday next (May 20), at three o'clock, Prof. Karl Pearson will deliver the first of three lectures at the Royal Institution on "The Laws of Heredity, with Special Reference to Man." On the following Thursday Mr. H. H. Spielman commences a course of three lectures on "Contemporary British Sculpture," with lantern slide illustrations; and on Saturday Prof. Brander Matthews gives the first of a course of three lectures on "The Development of the British Drama." The Friday evening discourse on May 23 will be given by Canon Ainger, his subject being "The Ethical Element of Shakspere;" the discourse on May 30 will be delivered by Mr. G. Marconi on "Electric Space Telegraphy," and that on June 6 by Sir Benjamin Baker on "The Nile Reservoirs and Dams."

Electrolytic Estimation of Iodine.—Mr. Erich Müller in a recent paper on the electrolytic estimation of iodine in the presence of bromine and chlorine, shows that when an alkaline or neutral solution containing various haloid salts is electrolysed, the iodide is quantitatively converted into iodate, which can be estimated by treatment with potassium iodide and titration with thiosulphate. To prevent the reconversion of iodate into iodide, the electrolysis is carried out in the presence of a little potassium chromate, which must be allowed for when titrating. The cathode used was a gauze of platinum wire 10cm. long and 0·5cm. thick, the anode a piece of platinum foil 14cm. square and platinised on each side; a current of 1 ampere for 1½ minutes is employed, and the E.M.F. must not exceed 1·7 volts or some bromide will be converted into hypobromite.

Formation of Ozone by the Electric Discharge. This subject was recently studied by Mr. A. de Hemptinne, who has now published his conclusions in the form of a paper. He finds, as a result of his research, that the amount of ozone produced by means of the electric discharge varies greatly with the distance of the tinfoil plates from one to another, and with their size. It is not proportional to the amount of air passed in a given time, and the pressure has apparently little influence. The intensity of the electrical current has also a very considerable influence on the amount of ozone formed, a current of low potential and high density being more advantageous than one of high potential. For a given value of electrical energy, there will be a given value of those different factors for which the formation of ozone is a maximum. The increase in the amount of ozone by employing oxygen instead of air is not sufficient to justify its use from an economic standpoint.

Glasgow Local Section.—Owing to the last report of the committee of the above section of the Institution of Electrical Engineers being delayed till the commencement of the present session, the second annual report, which was presented at the general meeting at Glasgow on Tuesday, only covers the work of the past six months. In that period seven meetings have been held, the attendance at which has been satisfactory, the average number present on each occasion being about 50. Although the papers submitted during the session have been few in number, they have all been of a very high standard. An increase of 31 in the membership of the section is shown for the past six months, bringing the total up to 189, which the committee regard as very satisfactory. With regard to the coming session the committee have already had some valuable papers offered, but they hope that members of all classes will support the section, not only by contributing papers, but by attendance at the meetings and by taking part in the discussions.

Institution of Junior Engineers.—At the meeting of this institution held on May 2 the paper read was on "Some Factors in Colonial Railway Construction," by Mr. Lewis H. Rugg. In the course of his remarks the author pointed out that from a financial point of view steep grades and high summit leads were desirable, it being quite a mistake to suppose and to agree with the popular idea that easy grades and curves resulted in a successful railway. Nothing less than 2ft. 6in. should be adopted per gauge; this was adequate for the sharpest curves. In dealing with surveys, the author pointed out that the tachometer was unfortunately still to a large extent ignored in this country. Its advantages were apparent, as it contained the theodolite, chain, and spirit-level in one. A vote of thanks was passed to the author, and the proceedings terminated with the announcement of the visit on May 10 to the Great Eastern Railway Works, and a special notice with reference to the summer excursion of the institution to Lancashire—Preston, Blackpool, etc.—Aug. 9 to 16.

New Literature.—We understand that a volume containing the physical papers of Prof. Henry A. Rowland, for 25 years professor of physics in the Johns Hopkins University, is now in preparation. The book will contain Prof. Rowland's articles and memoirs on physical subjects, together with his popular writings and addresses, numbering 60 in all. They have been collected from over 20 different magazines and journals. The subjects treated in these papers cover a wide range. In heat there is the great memoir on the mechanical equivalent of heat, with several shorter articles on thermometers. On the subject of electricity and magnetism there are the fundamental researches on magnetisation, on the magnetic effect of electrical convection, on the value of the ohm, on the theory and use of alternating currents, etc. In light the renowned discovery and theory of the concave grating and the long series of investigations made in the field of spectroscopy are described. The memorial address of Prof. Mendenhall and a portrait of Prof. Rowland will also be included. Orders for this volume at £1. 1s. per copy may be sent to Prof. Joseph S. Ames, Johns Hopkins University, Baltimore, Maryland.

Electricity Supply in St. Marylebone.—At the Surveyors' Institute, Westminster, there is at present in progress an arbitration enquiry, under the Lands Clauses Act, which is of great importance not only on account of the large sums involved, but because it is the first enquiry of the kind ever held. The proceedings are taken to decide the amount which is to be paid by the St. Marylebone Borough Council to the Metropolitan Electric Supply Company, Limited, for the acquisition by the Council of that portion of the company's electricity supply undertaking and business situate in the metropolitan borough of St. Marylebone. It will be remembered that last session the Council obtained parliamentary powers to purchase, and, negotiations as to terms of purchase having failed, the present arbitration has been resorted to. The result of the enquiry, which is likely to last for some days, will be watched with the keenest interest, as the question of elec-

Digitized by Google

tricity supply in St. Marylebone has long been the subject of conflict between the municipal authorities and the company. Mr. C. A. Russell, K.C., is the umpire, and assisting him in the capacity of arbitrators are Mr. Robert Vigers and Mr. W. C. Ryde.

Electromobile Trials.—We have received from the Automobile Club a preliminary notice with reference to the forthcoming trials of electric vehicles arranged by the club to take place from July 7 to 12 this year. Cars may be entered for either of the following classes: (1) town carriages; (2) country carriages weighing over 30cwt., including accumulators; (3) country carriages weighing under 30cwt., including accumulators. The following is the general arrangement of the routes chosen, but special optional routes will be selected for town carriages: (*a*) London to Brighton; (*b*) Brighton to London; (*c*) London to Sandown and back; (*d*) London to Windsor and back; (*e*) London to Ascot and back; (*f*) special route for observations. In order to enable the Trials Committee to make proper arrangements for the charging of cars, intending competitors are requested to inform the club secretary how many cars they propose to enter in the trials, and to state in respect to each car (*a*) the charging voltage at the beginning and end of charge, (*b*) the average current during charge, (*c*) the approximate time required for charging. Official entry forms, together with full programme of the trials, will be issued in due course.

Institution of Civil Engineers.—The students connected with the above institution held their annual dinner on Friday night at the Restaurant Frascati, Oxford-street, with Mr. C. Hawksley, the president, in the chair. In proposing the toast of "The Institution of Civil Engineers," Mr. H. E. Wimperis referred to the recent splendid endowments of the late Mr. Cecil Rhodes, and expressed the hope that some millionaire would similarly endow their institution. It was only after a training of some seven or eight years that the majority of young engineers was enabled to earn a living, and the supply of scholarships was an economic necessity. As showing the scarcity of scholarships there was in this country, he stated that there were not more than a dozen devoted to engineering which were of any value, and which were not tied to any particular locality In response, the chairman alluded to the fact that there were now five past-presidents of the institution who were over 80 years of age, which spoke much for the long life of engineers. Mr. W. H. Barlow, one of their past-presidents, had just attained the age of 90 years. Proposing "The Students," Sir A. Binnie remarked that scholarships might help to stimulate and assist them, but that would be a very false help if the students relied entirely upon them and neglected the study of nature.

A Cable Drill.—At a recent exhibition of agricultural machinery in Paris, there was on view a drill designed for quickly laying electric cables in a light soil or in sand. The machine was designed by Mr. Bajac, and it is proposed by him to use the apparatus to lay telegraph wires in the Sahara Desert. The cable is contained on a drum which is placed vertically over a hollow drill, which projects down into the ground the desired depth. According to the inventor, this depth may be as much as 3ft. This hollow drill has at the bottom a jockey pulley round which the cable passes, so that the drill has only to be drawn forward in order to uncoil the cables from the drum, which passes vertically down to this pulley, and is then laid in the ground at the depth mentioned. In the front of the hollow drill are two ordinary drill heads, which break up the ground in front of it, and in this way reduce the work which has to be done, and behind again is a small roller, which assists to press the earth down on to the cable after laying. There is no information in the description of the apparatus we have seen as to the power required to work this drill through various soils, and although it would do its work more quickly than with the ordinary digging, it seems to us there would be many cases in which its use would be debarred owing to obstructions in the ground.

Belated Transformer Patents.—In a recent issue we commented on the fact that the United States Patent Office had in March this year granted a patent to Messrs. Thomson and Houston relating to improvements in transformers the application for which was filed so long ago as Feb. 19, 1887. This record, however, has now been broken by another patent issued to Prof. Elihu Thomson last month on an application filed on Nov. 2, 1885. This latter patent claims a system of electrical distribution consisting of a number of transformers having secondary working circuits, and with the primaries in multiple on a single supply circuit. The claims of the previous patent were for transformers arranged in multiple, and for a system wherein the circuits supplied by the secondaries to the working circuits are of greater amperage and less potential than the current in the primary. Discussing the matter editorially, the *Electrical World* expresses the opinion that, in view of the fundamental claims of these belated transformer patents, they promise to provoke an interesting litigation in which, in all probability, the question would be taken up as to the validity of patents covering fundamental principles of an art which were not used until many years after the art which they would control had become perfected and of world-wide application. As we have before pointed out in these columns, the practice of granting patents years after the applications for the same have been filed is likely to be an injustice to the electrical industry. It is quite conceivable that the patents may be acquired by some large company and used for the purpose of hampering rival concerns.

Electrolysis of Brine.—An electrolyte cell recently patented by Mr. F. McDonald, and designed for the production of chlorine and caustic from brine, is described in the *Electrical World* as belonging to the type rendered familiar by the early constructions of Le Sueur and the later forms of Hargreaves and Moore, in which a perforated cathode is employed as a support for the diaphragms which enclose the anode compartment. The device now patented operates upon the Le Sueur principle, and is, therefore, to be considered as a modified form of this cell. The anode is formed of a number of platinum wires or ribbons fused into a glass tube, and contacting therein with mercury, through which the electrical connection is made. The details of construction are as follows: The iron tank is divided by perforated iron cathode plates, suitable flanged, into three compartments, of which the central contains anodes. The diaphragms, comprising layers of asbestos cloths, faced with asbestos paper, are supported by the cathode. The cover of the anode cell is sealed by cement into the upper flanged portion of the cathode plates, and the anodes are supported by this cover. A bed of cement covers the bottom and end walls of the anode compartments, and protects the iron from the action of the electrolyte. The lateral or cathode compartments are likewise tightly covered, and are provided with suitable induction pipes for water and with eduction pipes arranged to draw the caustic from the bottom of the cell. The anodes comprise a glass tube, into the lower end of which platinum wires are sealed. The anode conductor is in contact within the tube with mercury, as are the platinum wires. These wires constitute the working anodes, and hang freely in the vicinity of the diaphragms. The chief departure in

Digitized by Google

this cell from the Le Sueur type is the substitution of vertical perforated plate cathodes for the inclined bed of wire sponge originally used. The changes involve both the structure and position of the cathode, and both are said to be distinct advances on previous inventions in that they facilitate the free escape of the liberated hydrogen.

Municipal Telephones.—The connections to the Corporation telephone exchange at Glasgow are rapidly increasing, new orders coming in at the rate of about a dozen a day. According to a recent report by Mr. A. R. Bennett, the general manager of the municipal system, there are now 7,066 orders on hand, of which 5,055 have been executed, leaving 2,011 still to be connected. During the previous fortnight new orders were received at the rate of 13 per day, while subscribers were put on to the municipal lines at the rate of 23 per day. We understand that the system has been extended out to Clydebank, and many residents there are now connected with the Corporation exchange. With regard to the financial side of the undertaking, it is encouraging to find that it is quite satisfactory. After paying all working expenses, Post Office royalties, and interest of sinking fund on the whole of the capital expended to date, there remained a good balance for the month of April. Relief cables are now being laid in many parts of the city, notably for the Bridgeton and St. George's Cross districts. While on this subject, we regret to see that the same practice is being adopted at Eastbourne as was employed at Tunbridge Wells by opponents of municipal telephones, of writing anonymous letters to the Press. For the most part these "contributed articles," as they are called, are personal attacks upon Mr. Bennett, whose efforts in the direction of cheap telephony are naturally not welcomed by the telephone monopolists. The reasons for which these offensive anonymous letters are written and published in the local newspapers are so obvious that any comment on our part is unnecessary.

Steam v. Electricity on Railways.—In a recent discussion of this subject in the States, Mr. C. H. Davis expressed some interesting conclusions with regard to the economic electrical future of railways, which he has now embodied in a paper before the Canadian Society of Civil Engineers. To put it shortly, the author finds that steam railways will not in the near future handle their freight traffic (other than mail, express, and light local freight carried in suburban trains) and long-distance passenger traffic by any other motive power than steam locomotives, but there may occur infrequent cases in which electricity will be used under exceptional conditions of large volume and great density of passenger traffic. New railway lines connecting very large centres of population will, however, be operated by electric motors. Again, there are three conditions under which suburban and short-distance interurban traffic will be handled profitably by steam railways converted to electric traction—viz., where units can be light and frequent and operated over comparatively short distances, where gross receipts can be so increased by the change of system and mode of operation as to pay for the increased investment and possible increase in operating expenses, and where competition of parallel electric roads compels the change, to save what traffic there is, irrespective of how operating expenses are affected. Lastly, the author finds that in the future development of steam railway systems they will eventually be operated jointly with surface electric railways, either through mutual ownership or by traffic contracts, leases, etc. Dealing with the question of created or induced traffic, the author gives an outline of the general laws of passenger movement, although they are not as yet very clearly defined. Velocity of transportation, for instance, is not primarily effective in inducing travel, but together with other conditions it tends to increase traffic. These other conditions include proximity of departure and arrival points to possible passengers, frequency of service, and character of terminals. Also as the density of the districts served increase, it is probable that the riders *per capita* per annum also increase, while, again, the effect of various industries and the kind of population must have a decided effect on the passenger traffic. The author offers no detailed defence for these laws, but he thinks they will generally be found to be correct.

Molecular Surface Energy of Solutions.—The May number of the *Journal* of the Chemical Society contains a good abstract of a paper under the above title by Mr. D. Pekar, in which the method used for the determination of the surface tensions is first described. It consists essentially in the comparison of the curvature of the liquid contained in a narrow vessel with that of a liquid of known surface tension. The molecular surface energy was determined in the case of ethyl ether, carbon disulphide, and benzene. The values of the critical temperatures—that is, the temperatures at which $\gamma (M v)^{\frac{2}{3}} = 0$—for the compounds were found to be respectively, 187·7, 271, and 274 degrees, whilst the mean temperature coefficients are 0·230, 0·203, 0·233, indicating non-associated liquids (these numbers are not expressed in the same units, and are not directly comparable with those of Ramsay and Shields). In the case of mixtures of these compounds, although the molecular surface energy itself may not be the additive mean, yet the temperature coefficient is still normal, and hence, if the molecular weight of one component of a mixture is known, that of the other is calculable. This result is in accord with that of Ramsay and Aston, with which work, however, the author was not familiar until the end of his research. The molecular weight of sulphur was then ascertained by means of the determination of the molecular surface energy of its solution in carbon disulphide and in disulphur dichloride. In both solvents it was found that the dissolved sulphur has a molecular weight corresponding with S_6 or S_8, a result in accord with most determinations, but not with those of Orndorff and Terrasse, who, by the cryoscopic method, obtained the value 61·9 for the molecular weight of sulphur in disulphur dichloride solution.

Electrical Engineers Volunteers.—A Bohemian concert, given by the Electrical Engineers (R.E.) Volunteers' Cycling Club at the headquarters in Regency-street, Westminster, on Saturday evening, showed that the spirit of goodfellowship among the members of the corps has in no way died out since their return from South Africa, and a goodly number of young electrical engineers with their lady friends were present at this agreeable form of entertainment. The drill hall, in which the concert was held, was prettily decorated with flags and flowers, while on the platform itself a number of small electric incandescent lamps embedded among ferns and other greenery added to the brilliance of the gathering. Major R. S. Erskine occupied the chair, and was supported, among others, by Colonel Crompton, who is colonel of the regiment. The programme provided was of a well-varied description, and as the artistes warmed to their work, so the interest increased. To mention a few of those who kindly gave their services on this occasion, Miss Lilian Harvey, a delightful young contralto, was heard to great advantage in "Love the Pedlar," and later on in that favourite coon song which never fails to ensure an encore, "Ma Curly-headed Babby." Some excellent musical sketches by Mr. Griffith

Digitized by Google

Humphries deservedly found great favour with the audience, who warmly applauded his clever witticisms. Mr. Dennis Drew, a baritone, also gained a sympathetic hearing in "The Mermaid" and "The Border Ballad"; and among others who contributed to the evening's entertainment may be mentioned Sergeant G. D. Leys, Sapper S. S. Webb-Bowen, C.S.M. E. G Sheppard and C.S.M. G. A. Poynton. The concert throughout must be voted a great success, and it is to be hoped that the Volunteers' Cycling Club will give us many another like entertainment in the near future, as they will do much to popularise the club with the profession in this way. It may be mentioned here that one of the objects of the club is to promote social intercourse among members of the corps, and it seems to us a pity that although the club has now been in existence for over three years, it should not be more largely patronised by the younger members of the profession than it at present is. Compared with the long roll list of the regiment itself, the membership of the club is rather insignificant, but now that the summer is fast approaching, and the delights of long bicycle runs in the country may well be anticipated, it is hoped that the numbers will considerably swell. In our opinion the club is deserving of the most unselfish support.

Electrical Equipment of the Boston Elevated Railway.—A well-illustrated description of part of the electrical equipment of the Boston Elevated Railway appears in the current number of the *Wisconsin Engineer* from the pen of Mr. C. H. Hill. The article is practically devoted to a treatise of the method employed on this railway for the transmission of power, which is furnished from three of the company's power stations—all in the vicinity of the structure. In calculating the copper required for transmitting the power to the motors, a 2,000,000 circular mil. wire was determined upon as a unit in the feeder system. At the switchboard each feeder panel carries one carbon break circuit breaker, having a capacity for carrying 3,000 amperes continuously without heating, one ammeter measuring up to 6,000 amperes, and one quick-break switch having a capacity of 3,000 amperes continuously. The electrical current is carried from the station to the elevated structure, using 2,000,000 circular mil. lead-covered, rubber insulated cables, which are drawn in conduits built of vitrified clay pipe. The conductor in each cable is insulated with five-thirty-secs. of an inch of rubber compound, covered with a tape and protected with a lead covering $\frac{1}{8}$in. in thickness. At each end of the cables it was deemed desirable to discontinue the lead covering, and splice on from 40ft. to 60ft. of rubber-insulated triple-braided wire. Describing the third-rail system which is used in transmitting the power from the feeder system to the cars, the writer says that each car carries four contact shoes, carried outside the forward and rear trucks and hanging at such a distance as to come in contact with the third rail, which is so placed outside the running rails that its contact surface is 19$\frac{1}{2}$in. from the gauge of the running rail and approximately 6·2in. above. An ordinary "T" rail, 85lb. to the yard, is used for the third rail, the steel in the elevated structure throughout being employed as a part of the return system. In addition to this, one rail in each track constitutes part of the return circuit. The joints on the third rail are bonded nearly to the full capacity of the rail itself, and at 500ft. to 600ft. intervals the rail is bonded to the longitudinal girders of the structure. One rail of each track is used as a part of the signal circuit, and is, therefore, not available for the return system. As our readers may know, the Boston Elevated Railway Company own and operate surface lines in conjunction with the elevated system, and it has been found desirable to connect the elevated structure with the surface tracks and return wires at frequent intervals, thus giving a well-balanced return system.

The Institution Building Fund.—Mr. Langdon made a most encouraging statement at the meeting of the Institution last week with regard to the building fund, which we are sure will be read with the deepest interest by all members of the profession. It was to the effect that this fund has now reached the round sum of £10,000. In making the announcement, the President was anxious to congratulate the treasurer, Prof. Ayrton, on having accumulated that amount, and at the same time he wished to take advantage of this opportunity to ask members for their liberal support of this fund. After all, £10,000 was not a large sum towards the object they had in view, which was to obtain a representative building for the Institution of Electrical Engineers. The field before electrical engineers was undoubtedly a large one, and they might look forward to this Institution not only becoming a very popular but a very influential body in the future, and it was most desirable that they should one and all aim towards gathering together the means of providing a representative building for the profession at large. Such a building would not only be a great advantage to the Institution as a body, but it would also be a place of comfort and pleasure to individual members. Owing to the rapid growth in the membership and the consequent increase in the work of the executive, they were at the present time considerably hampered for want of accommodation. Of course, it was not to be expected that they would get a building entirely suitable to their wants for some time, but if they did not progress faster in the future than they had done in the past—having due regard to the fact that the Institution had been some 30 years in existence, and that during that time the amount accumulated was only £10,000—it would be many years before they got their building. He appealed to the members to put their shoulders to the wheel and help this fund all they could. The membership was now some 4,500 strong, and he pointed out that if every member made an annual donation of 10s., it would result in an addition to the fund of £2,000 or £3,000 a year. The advantage of having such a building as was proposed would be reaped by the whole Institution, and he earnestly appealed to every gentleman present that night and every member of the Institution, whether resident in London or in the provinces or in the Colonies, to lend their help towards the fulfilment of the object which they all had in view. In tendering these few remarks it must be understood that he did not forget in any way the great services that had been rendered them by the Institution of Civil Engineers. They had received at the hands of that institution the greatest courtesy and the greatest kindness, and he was sure they would always be prepared to recognise this. He trusted that all of them would do their utmost to contribute to this fund, so that it might be built up in the future much faster than it had been in the past.

Mr. Marconi on Wireless Telegraphy.—A large audience assembled in Kinnaird Hall, Dundee, one night last week to hear Mr. Marconi give an exposition of his system of wireless telegraphy, which has been long promised to the inhabitants of that city. At the outset the lecturer referred to the life and work of James Bowman Lindsay in connection with wireless telegraphy. Lindsay's system, however, was not at the time of practical utility, owing to the large amount of electrical energy required even for the most moderate distances, and also on account of the

Digitized by Google

considerable distance apart at which it was found necessary to place the two immersed plates connected to his circuit, but had he lived to the present time, when the developments of modern electrical engineering have placed such very powerful means in the hands of the electrician, Mr. Marconi predicted that Lindsay would have done as much as he himself was now able to do. In any case the name of James Bowman Lindsay must go down to posterity as that of the first man who thoroughly believed in the possibility and utility of long-distance wireless telegraphy. After describing the system elaborated in later years by Sir Wm. Preece and the discoveries of Clerk Maxwell and of Hertz—the direct precursors of his own system of æther-wave telegraphy—Mr. Marconi mentioned that in March, 1899, the first international communication by wireless telegraphy was established between the South Foreland and a village near Boulogne—a distance of 32 miles. At the present time his system was in use in no fewer than 40 coast stations (most of them controlled by Lloyd's) in Great Britain and in Europe; in 66 vessels of the British navy, and 12 vessels in the Italian navy. It has also been adopted by many of the Transatlantic lines of passenger and freight vessels, and by the Belgian mail steamers. As showing the commercial application of the system, he stated that lately the Cunard Company had received in receipts from the "Campania" for messages transmitted from passengers as much as £60 on one trip. Referring to the possibility of "tapping" the messages, Mr. Marconi said that the introduction of the tuning system obviated this difficulty. In his opinion the day was rapidly approaching when ships would be able to be in touch and in communication with the shore across all oceans, and then that isolation from the outside world still possible on board ships would be a thing of the post. The possibilities of the system on land, especially between this country and the Colonies, would be much more far-reaching. It should be mentioned, in conclusion, that Mr. Marconi hopes to have his Canadian station ready in about eight weeks, when, as he put it the practicability of a Transatlantic service will be determined.

The Proposed General Conditions.—The adjourned discussion of the proposed form of model general conditions for use in connection with contracts for electrical plant was taken up by Mr. G. H. Nisbett last week at an extraordinary meeting of the Institution, held in the rooms of the Society of Arts. Continuing his remarks from the previous meeting, Mr. Nisbett argued that the form had not been drawn up with due regard to the interests of the contractor. Looking through the conditions, he found that there were 57 clauses which safeguarded the interests of the purchaser, as against only 17 that gave any rights at all to the contractor. He complained, for instance, that no provision had been made for penalties in the event of non-fulfilment of the contract by the purchaser, and suggested several other additions and amendments with a view to putting the contractor on a more level footing with the purchaser. He pointed out, further, that whereas the purchaser had the power to reject any machinery which did not come up to the test, the contractor was quite unprotected in this respect, and he suggested that the contractor should be allowed a period of, say, one month in which to make good defects. Mr. Stuart Russell supplemented these remarks with a few other suggestions in favour of the contractor, and was followed by Mr. C. C Hawkins. It was most important, he said, that the contractor should maintain his free and undisputed right to appeal to arbitration on any matter whatever, and he asked that this might be made perfectly clear in the model conditions. Again, while the contractor was perfectly willing to admit his liability for damage to plant when in course of erection, the present clause relating to this subject was so loosely worded that it laid him open to any claim for damage whatsoever that the purchaser chose to prefer against him. Mr. J. E. Kingsbury, in looking through the form, was struck with the good work which the committee had carried out, and he was sorry to note that some captious criticisms had been indulged in concerning it. He heard it remarked, for example, that the conditions were in favour of the buyer, and he asked, what prospect was there of getting any form of general conditions used that was in favour of the seller? He was glad to see that the committee in drawing up these conditions had taken the advice and assistance of representative bodies of contractors and manufacturers, so that they really did have a hand in making the laws under which he hoped they were going to be ruled. Mr. J. Shoolbred having spoken in favour of the document, Mr. W. B. Esson took up the discussion with the remark that if these conditions were going to be made fair to both sides, they must yet have considerable modification, pointing out that what would apply to the building contractor was not fair for the contractor who supplied and installed machinery. Dealing with the clauses, he urged that the provision which made the contract subject to the sanction of the Local Government Board should be struck out altogether. Another suggestion which he made was, that it should be specifically stated in the form that the purchaser was liable for any damage to machinery in course of erection which was not directly attributable to the fault or neglect of the contractor. He also thought that the onus of applying for an extension of time for the completion of works should not be put upon the contractor, but that the consulting engineer should give it without any application being necessary. Mr. W. E. Gray expressed the view that nothing had been said during the discussion which would weigh materially against the adoption of these fairly generous model conditions. Mr. N. Gunz was glad to note that provision had been made for the payment of penalties on the part of the purchaser in the event of his not taking delivery according to contract. Mr. C. H. Yeaman suggested that, in order to avoid a misunderstanding between the purchaser and the contractor, the latter should send in drawings with his tender, and that in the period between the acceptance of the tender and the signing of the contract these drawings should be altered if necessary, and agreed upon finally. Mr. Robert Hammond, who is acting as reporter to the committee which framed the conditions, made a few remarks in reply to the discussion. He assured the contractors present that the committee was by no means an anti-contractors' committee. It would be his pleasure to lay the views of those members who had spoken before the committee, and endeavour to produce a set of conditions which would be acceptable, not only to the contractors of the country, but also to the town clerks and solicitors of the purchasers. He appealed particularly to the Institution, however, not to press the committee to lay it down that the contract must be delivered absolutely in its final form, with complete drawings, before the contract was signed. They must allow the contractor a little latitude with regard to his drawings. He maintained that the best thing for the industry was to encourage the engineer to state exactly what he wanted, so that the contractor should know perfectly what he was called upon to supply. On behalf of the committee, he thanked the Institution most heartily for giving a second evening to the discussion of these conditions, and he assured the meeting that every suggestion that had been made would be most carefully weighed by the committee in preparing the form for final adoption.

CARDIFF ELECTRICAL TRAMWAYS.

(Concluded from Supplement.)

There are seven main feeding points at Cardiff. To five of these points feeders having conductors of ·6 square inch sectional area are taken, the remaining points being fed by cables of ·5 and ·4 square inch sectional area respectively. Two negative feeding points are further provided. One of these is situated at the junction of Castle-road and Newport-road, and the other at the junction of Custom House-street and Bute-street. To the former are run two cables, each of ·6 square inch sectional area, and to the latter three cables, two of ·8in. and one of ·6in. sectional area. Special care has been taken to ensure good earthing, all the negative feeders being earthed at the negative feeding points. All the cables are of the lead-covered, paper-insulated type, and were supplied by the British Insulated Wire Company, Limited, Prescot. They are drawn into conduits supplied by Messrs. Doulton and Co., Limited, Lambeth, London, E.C. These conduits are of the three-way stoneware type, each way measuring 3in. by 3in., and were laid by the Corporation. They are jointed with cement, the method of building them up in concrete being clearly shown in Fig. 23. Starting from the generating station, no less than 10 conduits are built up as shown,

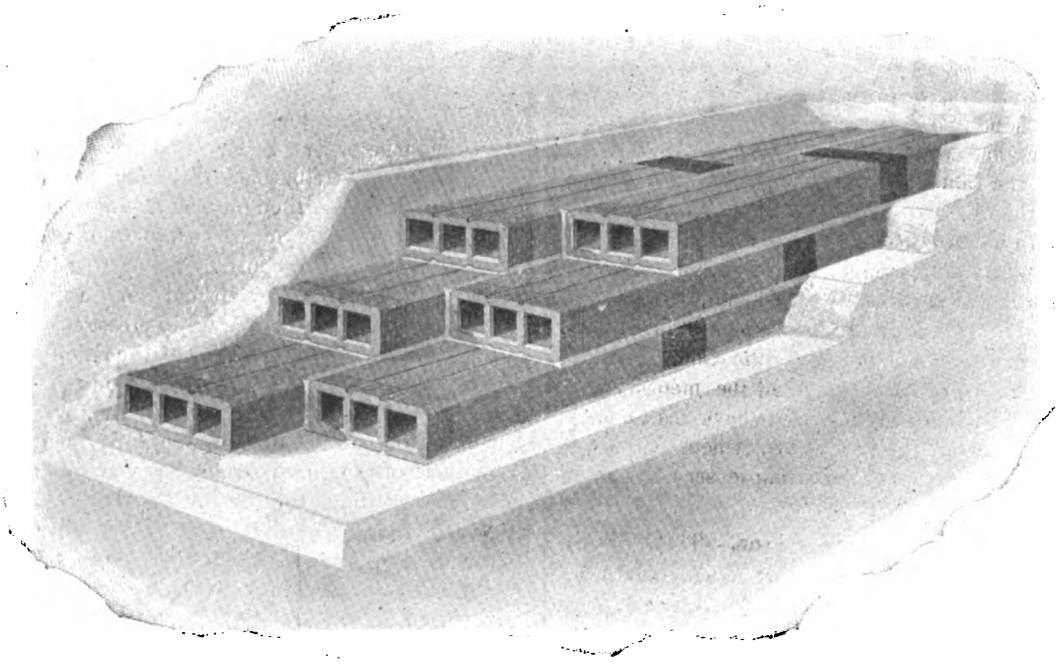

FIG. 23.—Method of Building Up Doulton Conduits in Concrete, Cardiff Electric Tramways.

thus providing 30 ways, which allows ample scope for future extensions of mains. Armoured cables are laid from the station to the first road box where the conduit commences. It should be mentioned that a three-core combined pilot and telephone cable is run to the end of each route, one core serving as a pilot and the other two as telephone wires. A pilot wire is also run to each of the negative feeding points. In all there are 12 pilot wires and 14 points to which they connect. Eventually there will be 10 separate routes, but at present there are only eight. The telephone pillars are of the British Insulated Wire Company's make, and each contains a telephone test box. It may be mentioned that the work of laying the cables has been superintended on behalf of the British Insulated Wire Company, Limited, by their engineer, Mr. F. Bradford, who is now engaged with the separate network destined to supply power to the docks and for general lighting purposes.

Section Boxes.—These are of the standard type supplied by Messrs. Bergtheil and Young, 12, Camomile-street, Bishopsgate-street Within, London, E.C., and are fitted with this firm's patent "L"-type switches. It will be seen from the illustration (Fig. 24) that the switch consists of two copper blades secured so that they move together, and separated by a distance-piece to allow the switch lever to lie between them in the closed position. This arrangement reduces the height from the base upon which the switch is mounted to a minimum, and enables the depth of the box to be kept correspondingly small. The arrangement of the switches on one of the section-box panels is shown in Fig. 25.

We understand that the connections are such that any section of the trolley wire can be fed from either end. The advantage of this is that in the event of the distributing cable between two section boxes breaking down, the faulty section can be bridged by means of the trolley wire until the fault in the cable has been removed. Presumably in regular working the double connection to each section of the trolley wire will not be used.

Overhead Equipment.—The chief feature with regard to the overhead work at Cardiff is its solid construction The work of erection has been carried out by the Corporation, the poles, bracket arms, and line material being supplied to them under separate contracts. Centre poles with double bracket arms predominate. These poles and arms have a light and elegant appearance despite their substantial design. Where span wires are employed, the supporting poles are provided with exceptionally heavy bases. All the line material was supplied by Messrs. Robert W. Blackwell and Co., Limited, of 59, City-road, London, E.C., and is of their Liverpool type with extra heavy ⅜in. Ætna insulating bolts. The single and double pull-offs are made of phosphor bronze in order to obtain greater tensile strength. It should also be mentioned that the ears used were designed by Mr. Ellis, and secure greater strength than is usual. The illustration (Fig. 26) is the only one we have of the line work. We are afraid it does not show much detail, but it will serve, at any rate, to illustrate the knowledge of the local Press on things electrical.

Rolling-Stock.

The rolling-stock comprises three types of cars—namely, double-deck bogie cars, mounted upon four-wheel maximum traction trucks: single-deck bogie cars, similarly mounted; and double-deck four-wheel cars, with fixed wheel bases.

Double-Deck Bogie Cars.—A full view of one of the first-mentioned type is shown in Fig. 27, while in Fig. 28 the arrangement of the reversed stairway with half-way platform is seen to greater advantage. These cars each provide seating accommodation for 68 passengers—30 inside and 38 outside. They are very similar in design to those supplied to the London United Tramways Company, Limited. The principal dimensions are as follows:

Length of car body outside	22ft. 3in.
Length of car body inside	21ft. 4in.
Length of each platform	5ft. 9in.
Length over platforms	33ft. 6in.

Digitized by Google

Width over roof	7ft. 0in.
Clear height inside at centre	6ft. 0in.

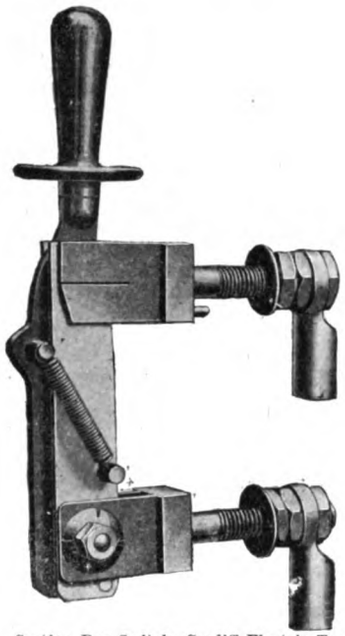

FIG. 24.—Section Box Switch, Cardiff Electric Tramways.

Distance between centres of driving axles	14ft. 6in.
Gauge	4ft. 8½in.
Height from level of rails to trolley plank	9ft. 0in.

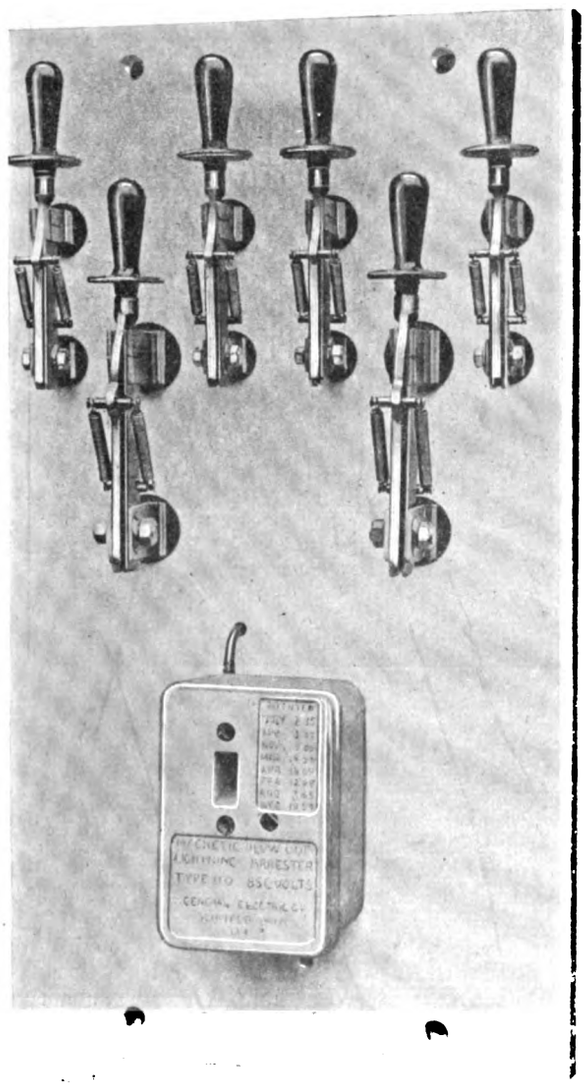

FIG. 25.—Arrangement of Switches on Section Box Panel, Cardiff Electric Tramways.

It will be gathered from the above dimensions that the platform at each end of the car projects 5ft. 9in. beyond the end of the car body. A collapsible gate is provided at each end of the car over the openings for the steps. The roof seats are of the reversible (garden) type. The lighting of the cars, both inside and outside, is very complete, as also the systems of bells and signals. A special circuit is

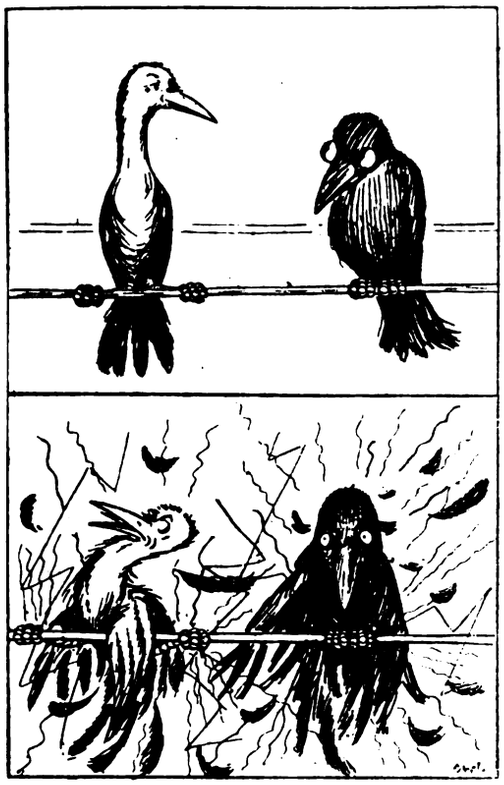

FIG. 26.—An Electric Shock.

First Cardiff Bird: Dear me. The Corporation are very considerate—providing such nice clothes-lines.

Second Cardiff Bird: The Cardiff Corporation are always in the van of Progress. Oh——O——O——D——.

(Just then the electric current was turned on at Roath Station.)

provided for illuminating the destination boxes, also for earthing the trolley standard through a ruby lamp fixed at each end of the car.

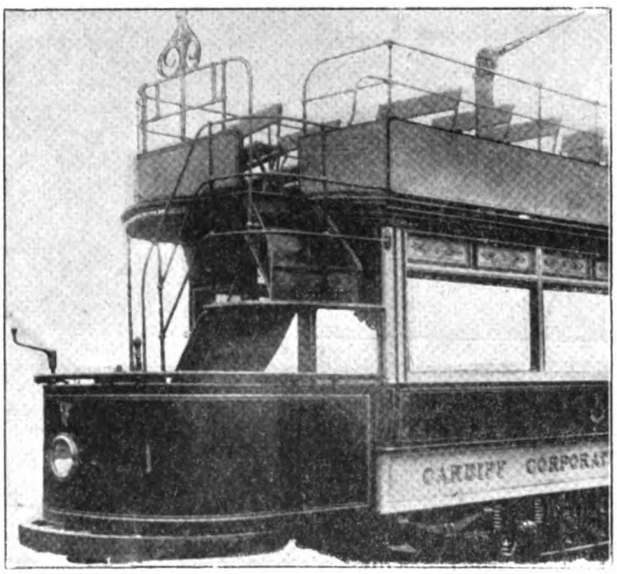

FIG. 28.—End View of Double-Deck Bogie Car, Cardiff Electric Tramways.

Single-Deck Cars.—These cars each provide seating accommodation for 34 passengers. The principal dimensions are as follows:

Length of car body outside	25ft. 0in.
Length of car body inside	24ft. 4in.
Length of each platform	3ft. 9in.
Length over platforms	32ft. 6in.
Width over roof	7ft. 0in.
Height inside at centre	7ft. 9in.
Distance between centres of driving axles	17ft. 6in.
Gauge	4ft. 8½in.
Height of end-door openings	6ft. 1in.

Digitized by Google

Double-Deck Four-Wheel Cars.—These cars each provide seating accommodation for 52 passengers—22 inside and 30 outside. The principal dimensions are approximately as follows:

Length of car body outside	16ft. 0in.
Length of car body inside	15ft. 4in.
Length of each platform	5ft. 9in.
Length over platforms	27ft. 6in.
Width of roof	7ft. 0in.
Clear height inside at centre	6ft. 0in.
Wheel base	6ft. 0in.
Gauge	4ft. 8½in.
Height from level of rails to trolley plank	9ft. 0in.

Details of Equipment.—Each of the cars, irrespective of type, is fitted with two controllers—one on either platform. Each of these controllers has 14 operating points—viz.: motors in series—three resistance points and one running point; motors in parallel—three resistance points and one running point; on braking side—six points. The electric braking is effected by the controller connecting the motors as series generators in parallel with one another, and in series with the same resistance as used for starting the car. The four-wheel cars are fitted with trucks of the Brill No. 21 type, while the bogie cars are mounted on Brill maximum traction trucks. Each of the latter has a wheel base of 4ft., the other dimensions being as follows:

Centres of side frames	5ft. 9½in.
Length of axle	6ft. 4⅞in.
Extreme width over all	6ft. 6¾in.
Centre of motor axle to bottom of car sill	11in.
Diameter of driving wheels	30in.
Diameter of small wheels	20in.
Diameter of driving axle	4in.
Diameter of small axle	3¾in.
Diameter of large journal	3⅞in.
Diameter of small journal	3in.

The compression device fitted to these trucks consists of a plunger supported by a large spiral spring held in position by a malleable iron casting, bolted to the cross-bar of truck, arranged with set nuts on the under side of the plunger head, so that the weight from the downward pressure of the compression device plate on the car body may be increased or decreased as required by the conditions under which the trucks are to be operated and the weight which may be required on the small wheels. Two series-wound motors are fitted to each car. Each motor is designed to give 1,400lb. draw-bar pull, with 30in. car wheels, and at this load, with a pressure of 500 volts at the motor terminals, is capable of operating the car at a speed of eight miles per hour. The motors, which are of the four-pole type, are capable of carrying the above load for one hour, and 100 per cent. overload for short periods, without undue heating or sparking. The armatures are geared to the car axles by means of a single-reduction spur gearing. The field magnets consist of four poles projecting radially inwards from a cast-iron frame, but the armature connections are arranged so that only two sets of brushes

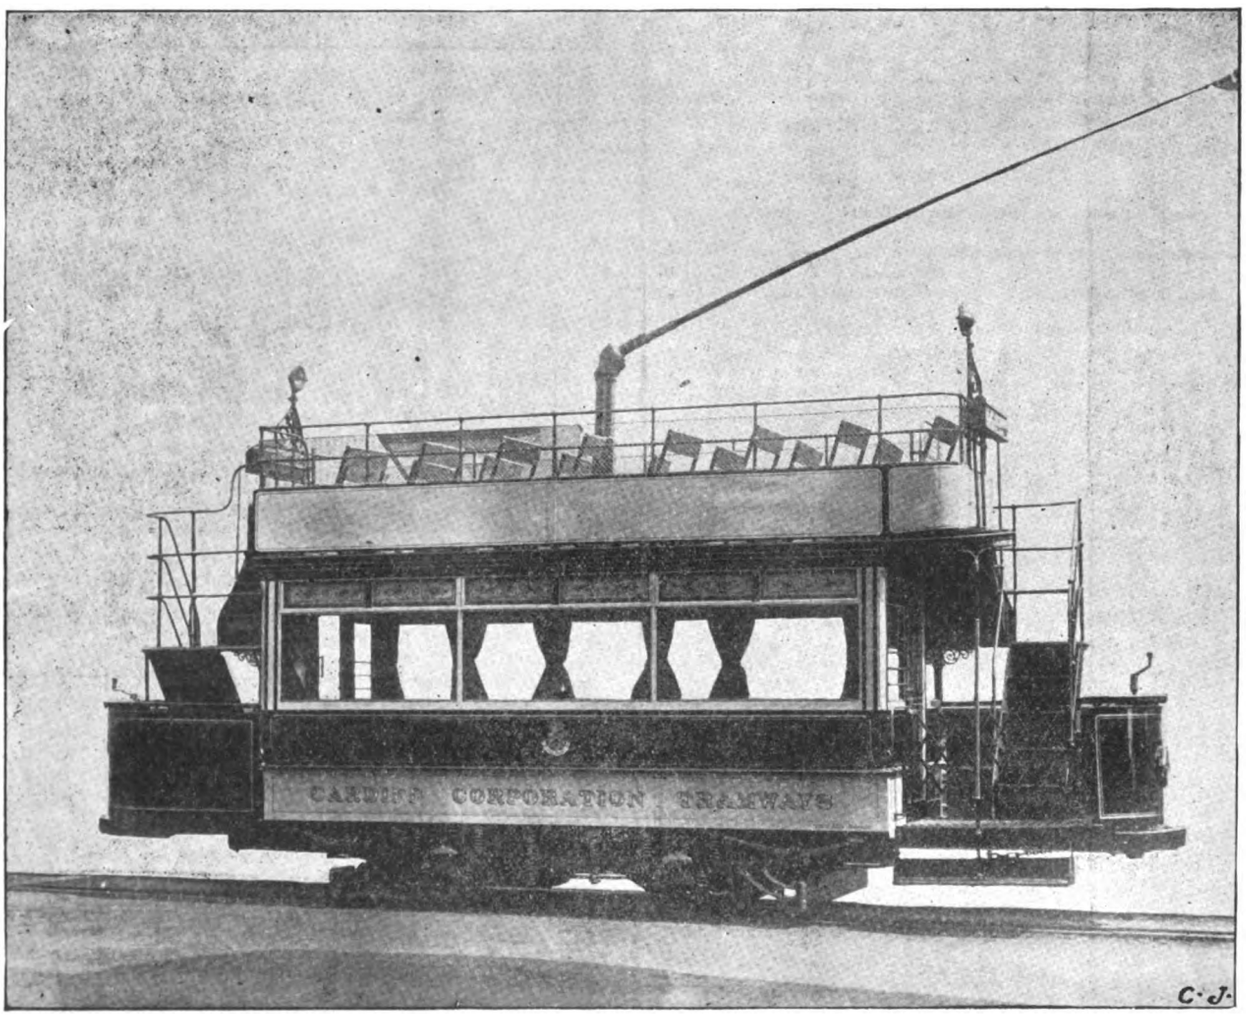

Fig. 27.—Double-Deck Bogie Car, Cardiff Electric Tramways.

are necessary. It may be mentioned that the insulation of the armatures and field coils from the frames was subjected to a pressure test of 3,000 volts alternating. Another point worthy of note is that all the wheels of the cars have been manufactured by Messrs. John Baker and Co. (Rotherham), Limited. The driving wheels are made in accordance with the firm's registered design (No. 356,095), while the pony wheels are of the disc type. In both cases the wheel centres are made of solid forged wrought iron, and are fitted with renewable steel tyres, which are weldless and are made from the very highest possible quality of Siemens-Martin open-hearth acid steel. During the execution of the order careful mechanical tests have been made from each batch of tyres, the lowest results being 52½ tons tensile strain, 14 per cent. elongation, on test pieces 2ft. long. In addition to this, the test tyres have been placed in a hydraulic press, and compressed cold to the extent of 4in., in no case showing the least sign of fracture or distress, the percentage of carbon

Digitized by Google

being 0·63. The wheel centres are, as already stated, of solid forged wrought iron, the driving wheels being somewhat similar in design to a locomotive wheel. It has been found that this type of wheel runs almost noiselessly; in fact, it is claimed to be the most silent wheel made, while as regards durability, the wheel is expected to run about four or five times as long as the old pattern wheel. Freedom from broken or snipped flanges, which play such havoc with the track, especially with the points and crossings and curves of short radii, is another advantage claimed for the wheel. When the tyres are worn out it is not necessary to scrap the wheels, as new tyres can be fitted at comparatively small cost, and the wheel becomes as good as new again, the wrought-iron centres being practically everlasting.

The cars themselves, it should be stated, together with their equipments, were supplied by Messrs. Dick, Kerr, and Co., Limited, 110, Cannon-street, London, E.C., the bodies being manufactured by the Electric Railway and Tramway Carriage Works, Preston, and the equipments by the English Electric Manufacturing Company, of the same town. There are in all about 120 cars on order.

We are indebted principally to Mr. Harpur and the various contractors concerned for the particulars and drawings which have enabled us to compile the above article.

ECONOMICAL INSTALLATIONS IN VILLAGES.

BY B. C. H. J.

It is likely that the end of the tether will shortly be reached as regards the profitable supply of electricity to towns and villages other than those which now have installations of their own or are within a power company's area of supply—that is, if the same conditions of plant and working are observed, and no sweeping invention occurs. Under the conditions prevalent in present practice, there is too little chance of paying interest even upon capital expended to make the enterprise worth the risk. But there are plenty of small towns, and even hamlets, where a revised arrangement of present-day practice would result in profit to all concerned; and the gist of the method proposed by the writer is electricity (1) generated as a joint product, and (2) distributed on simpler lines.

As regards the first clause, there are various methods open. In most small towns and villages there are factories of some description which have steam plant that is worked only during the day, and usually intermittently during that period. In some cases where the factory is lit and worked by electricity, there is practically nothing more to be done to start the concern than to set up a separate switchboard and to lay the mains. The building, boilers, engines, and dynamos are all there, and can be added to as results direct. This is an exceptional instance, of course, but take the more usual case of a factory run by shafting, and lit by gas. Here the building, boilers, and engines are provided, and a dynamo, switchboard, and perhaps cells, would have to be installed, the cost of these latter being but a small proportion of the former. The attendance bill also would also be reduced, as the engine-man at the mill would bear a hand, at an increased wage of course, and with the system of mains to be described, nothing could happen outside that could not be seen and rectified without using specially skilled labour. In the event of half a dozen or more of these joint installations being within reasonable distance of one another, a skilled man could be engaged to pay weekly visits of inspection, or to be called upon in case of accident.

Now as to the mains: time-honoured custom must be put upon one side for economical first cost. Whatever may be done with the feeders in the way of laying underground in conduits or troughs, or armoured direct, the writer recommends for the distributors bare hard-drawn copper wires slung to glass (as being stronger than porcelain) insulators upon wooden cross-arms supported by ordinary scaffold poles, about 18ft. long and fixed about 150ft. apart. This is an easily installed system, cheap in upkeep, and offering facilities for altering the sectional area of the conductors with a minimum of expense. Thus in putting up these mains there is no need to lock up more capital than will be earning money: a size of wire can be erected just suitable for current requirements. Should an unlooked-for increase in demand take place, then another wire could be slung up alongside the original one or the latter replaced by a thicker wire. The current in the distributors of such small towns as would perforce have to use this method would not require abnormally heavy wires, but if much current was required, then it would pay to put down proper underground mains. Services from the overhead wires would present no difficulty, and besides being cheap on account of the absence of excavating and joint-box, would be open to inspection, and likely to make the local professor of jointing more particular than where his joints were covered in and left, until the blown fuse should reveal the lack of filling compound or the fitting out of place. With this method the problem of cheaply lighting thoroughfares would be a simple one, by means of a bracket on each post, and a push-and-pull switch at the usual lamplighting height; watertight holders being, of course, a necessity.

The beauty of this arrangement, from the point of view of the cautious business man, largely consists in the diminution of risk. Should, by reason of any unthought-of contingency, the enterprise come to grief, there is little that need be wasted. Dynamos and switchboards are saleable second-hand commodities if properly advertised, and the overhead mains can be easily reeled up again on to drums and will fetch about 60 per cent. of their original value as scrap copper. The poles, too, are marketable wherever there is a house decorator's business.

Now, if a station is set up with underground mains throughout there is much larger amount of capital to pay interest upon, that must be absolutely unremunerative; for it is impossible to exactly calculate the demand of a district, or even a street, beforehand; and, if unsuccessful, the buried cables or conduits would cost as much as they were worth to exhume. The buildings would also be of little value if a separate station was built and came to grief.

To an ambitious promoter content to start in a small way, this beginning would probably pave the way to the establishment of other factories and of forcing houses for horticultural plants, light railways, and at the proper time, no doubt, a more orthodox central station could be erected to cope with the demand created.

It is likely that this class of work will be more prominent in the near future, if only promoters can avoid running up against consulting engineers of the class that thinks firstly of the 5 per cent. commission; secondly, of the advertisement to themselves of a gilt-edged central station with fancy machinery specially built to specification—and ninthly, of whether the concern will ever pay. There may then be better times coming for the fittings manufacturers and installation contractors of this country, and eventually more demand for generators and cables.

FORMERS AND FORMER-WINDING.

BY F. W. DAVIES.

(Continued from page 658.)

II. Formers for Field-Magnet Coils.

The formers for field-magnet coils not being used to any great extent, it is unnecessary to devote much time to a description and consideration of them. The expedient of winding the coils of a field magnet on a former is one that was thought of and put into practice at a comparatively early date. To devise a suitable former for field-magnet winding is a matter presenting but little difficulty. The principal point requiring attention is the method of removing the former from the coil when wound. The simplest former (which is also the most inefficient) consists of a plain block of hard wood of slightly larger section than the magnet core. It must be made larger in order to allow for the insulation. On this block, which is placed between centres for winding, the coils are wound. Owing to the difficulty of keeping the wire in its place at the end of the coil during the process of winding, and especially when removing the former from the coil, each layer has usually

Digitized by Google

two turns of wire less than the preceding layer, and sometimes four turns less. Such a method of winding is known as a "step" or coned winding, owing to the coned appearance presented at the ends of a coil wound on this method (Fig. 1). To avoid any possibility of the coil becoming disintegrated, four or more lengths of strong cotton tape are laid on the former before commencing to wind; and when the coil is wound these are brought over the ends and inserted under two or three turns of wire on the outer layer, as shown in the figure. One *supposed* advantage of the "step" winding is that coils wound in this fashion keep cooler, owing to the slightly greater cooling surface which this winding presents; but in practice this slight increase of cooling surface is quite negligible.

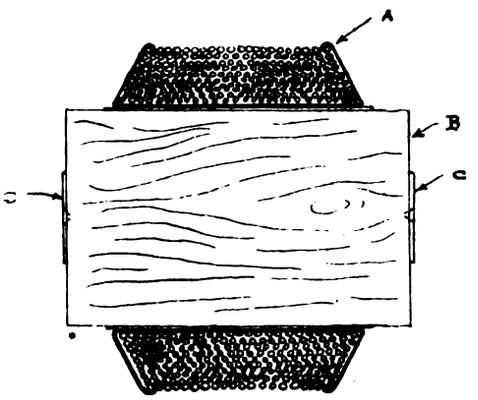

FIG. 1.—Section through Magnet Coil, wound on Simple Block Former. (A, coil; B, former; C, metal plates drilled in the middle for centres.)

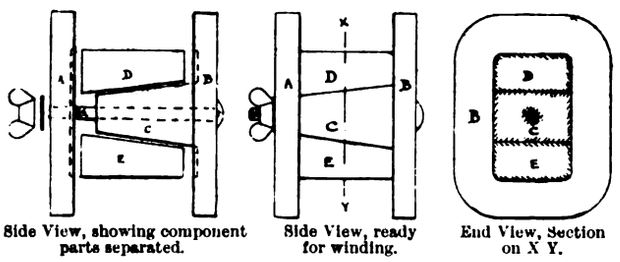
The simple block former just described is now practically obsolete, on account of the great difficulty there is in withdrawing it from a coil after winding. To facilitate its withdrawal from the coil, the former should be made of several wedge-shaped sections. There are various methods of constructing such a former, but it is not necessary to enumerate and describe them all, as the differences in them are very slight. A good former of simple construction is shown in Fig. 2. In one view it is shown with the component parts separated from one another, while the other two views represent the former built up ready for use. To remove the former from a coil, unscrew the wing-nut and remove the left-hand flange, A. Then withdraw the wedge, C (to which the right-hand flange, B, is permanently fastened). This done, the loose pieces, D and E, can easily be removed from the coil. A former of this description



Side View, showing component parts separated. Side View, ready for winding. End View, Section on X Y.

FIG. 2.—Divided Block Former (A and B, flanges; C, wedge fixed permanently to flange B; D and E, removable wedge-shaped blocks.)

can be removed from a tightly-wound coil with the greatest ease, and on this account it is immeasurably superior to the simple block former. In this case, also, it is well to bind the coil together with a few pieces of strong cotton tape in the same manner as for a "step"-wound coil. It would be quite possible to wind a coil on the divided block former shown in Fig. 2 with a "step" winding; but, as has already been pointed out, the advantage gained thereby would be extremely slight. Besides this, there are fewer turns of wire on a coil so wound than there are when the coil is butt-ended. It is usual to insulate the coils by binding them all over with cotton tape (Fig. 3), after which they are "served" with insulating varnish. By this means, the possibility of any of the turns of wire in the coil becoming loose is avoided, and it, moreover, gives the coil a neat and compact appearance. Before beginning to wind a coil a layer of stiff paper (preferably with a glazed surface) should be wrapped round the former in order to prevent the wire from making grooves in the wood; for the formation of such grooves makes its withdrawal a difficult operation. The finer the wire with which it is wound, the more paper should there be put on, as with fine wire the coils contract to quite an appreciable extent when taken off the former, especially at the corners.

For bipolar field magnets of the horseshoe type, the use of former-wound coils is not advisable, as they are very liable to damage on account of their exposed position. They are eminently suitable for the field magnets of motors of the protected and enclosed types. There is no reason why they should not be more extensively used for dynamo field magnets when these are of the "iron-clad"

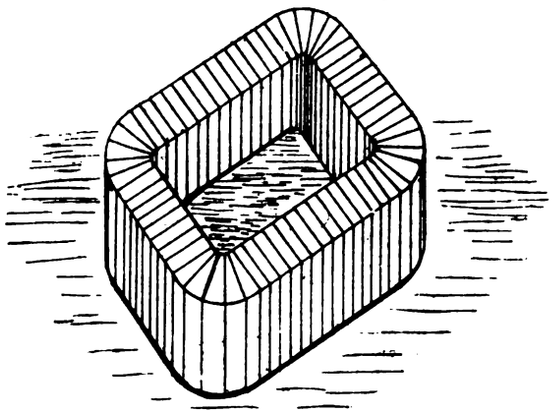


FIG. 3.—Perspective View of Field Magnet Coil. (Taped all over.)

type, as in this type of magnet the yoke usually overhangs the coils to some little distance, and thus forms an adequate protection for them.

When either a simple shunt or series winding is used for the magnet coils, no special difficulties present themselves; but when the coils are compound wound the case is not so simple. The problem which then presents itself is to find the most advantageous arrangement of series and shunt coils. If the series coils are wound on the top of the shunt coils, there will be a danger of the latter being damaged by the heavier wire or strip used for the series coils.

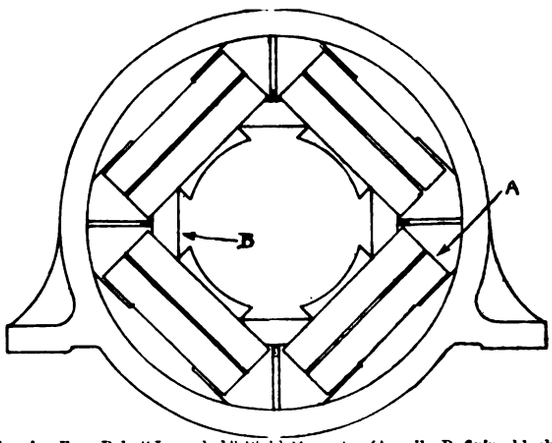

FIG. 4.—Four-Pole "Iron-clad" Field Magnet. (A, coil; B, fixing block.)

On the other hand, if the series coils are put on first, the arrangement is not a convenient one for bringing out the ends of the series winding. The best plan appears to be to place the series and shunt coils (which should be wound independently) alongside one another on the core. It is immaterial in what relative position they are placed—that is to say, it does not matter whether the series or shunt coils are placed the nearer to the pole-pieces.

That the field-magnet cores should be cast with the yoke is obviously desirable from the manufacturer's point of view. But it is not always possible to get the coils on when this is done, especially in four-pole machines, as the distance between the tips of adjacent pole-pieces is frequently very limited. In order to be able to get the coils on in the case of a four-pole machine, two of the cores, or more often all four of them, are by many makers cast separately from the yoke, and then bolted on to it after the coils have been placed in position. The expense

Digitized by Google

of doing this can be avoided by the simple expedient of winding each coil in sections—that is, by using, instead of one long coil, two short coils, each of one-half the length; or three short coils, each of one-third the length. It is then a simple matter to get them in place on the cores. In actual practice it will usually be found sufficient to wind each coil in *two* sections. A four-pole "iron-clad" magnet with the coils wound thus is shown in Fig. 4.

When the cores are cast with the yoke it is necessary to adopt some means of keeping the coils in position, as the pole-pieces are of necessity not enlarged like they are when the cores are cast separately. There are various methods of fixing the coils in position. Perhaps the best method—certainly the cheapest—is that shown in Fig. 4. A number of blocks of hard-wood or other suitable material (the number being, of course, the same as the number of poles) of a section similar to that shown, and about as long as the polar face (measured parallel to the shaft), effectually keep the coils in position. The blocks are fixed by means of small screws or bolts passing through the yoke of the magnet.

(To be continued.)

ELECTRIC TRACTION PROGRESS.*

BY PHILIP DAWSON.

The real advent of electric traction in England may be said to date back to the opening of the Bristol line in 1895. The Bristol electric tramways, although not by any means the first opened, was the first electric line which was commercially successful from the beginning. Since that date enormous progress has been made, so that at the present day there are 85 electric tramways and railways in actual operation, while there are over 100 tramways and light railways under construction or conversion, which are intended to be worked electrically. The following figures give a very good idea of the state of things at the present day:

ELECTRIC TRAMWAYS AND RAILWAYS IN THE UNITED KINGDOM.

	Route mileage.	Track mileage.	Number of cars.
Constructed (approximate)	800	1,300	4,000
Under construction	600	900	800
Authorised and about to be constructed	1,000	1,400	—
Total	2,400	3,600	4,800

I have compiled a series of tables which I thought would be of interest to you, and would give you an idea of the cost of installation and operation, as well as of the probable results which may be expected. There is no time to read through these figures to you, but from the printed copies which I have here you will be able to study them at your leisure. I have also compiled some figures showing the enormous increase of traffic which takes place when electric traction is introduced and the rapid growth of electric traction. This system is no longer in its infancy, and it has not only been applied with remarkable success in the United States and on the Continent of Europe, but it has within the last six years found great favour in our country, and the importance which it has attained may be gauged by the capital which has already been invested in it.

In 1896 the total capital invested in electric undertakings in this country was about £6,000,000. No corporation had at that time invested any money in that branch. At the end of last year the total capital invested by private companies exceeded £40,000,000, and municipalities had invested over £11,000,000, making a total investment of over £51,000,000. The schemes of power distribution may, for our purposes, be also counted in, as a large number of them will undoubtedly supply electric current for traction purposes. The capital which has already been raised for such undertakings amounts to nearly £20,000,000. If we take into consideration the new tube railways, and the conversion of the Metropolitan and District Railway to electric traction, which that successful American financier, Mr. Yerkes, has now in hand, we shall have to add another £20,000,000; it will thus be seen that, taking all the power distribution and traction schemes which are now either completed or under construction, the total amount of money invested reaches nearly £100,000,000. Taking the capital expended on electric light undertakings, we find that the municipalities have spent, in round figures, £16,000,000 and private companies £28,000,000. It will be seen from these figures that the subject which I am considering to-night is therefore a very important one. The enormous increase of electric traction in the United States is remarkable; thus, while in 1894, of the total tramway systems in America, amounting to nearly 13,000 miles, 9,000 miles were operated electrically. At the present moment over 20,000 miles are operated electrically, and approximately 60,000 cars are in circulation.

The total station capacity in kilowatts installed for lighting and traction purposes in the United Kingdom amounts to above 500,000 kw., and that at present being installed in the neighbourhood of 150,000 more. The total station capacity installed in London for all purposes is not much over 100,000 kw. This sounds a great deal, but if we compare these figures to those of New York City, we find that New York has nearly 250,000 kw. You may be interested to have some figures showing what surface lines or tramways have done in other towns. Taking New York City

* Paper read at Northampton before the Tramways Committee and others.

TABLE I.—New York City Surface Lines (from *Street Railway Journal*).—Population, 3,370,000.

—	1901.	1900.	1899.	1898.
Miles of track	963	952	930	914
Passengers carried	871,799,558	816,661,361	753,740,052	679,967,283

TABLE IV.—Approximate Cost of Various Parts of Electric Traction System.

Approximate Cost of Modern Power Plant per Kilowatt Installed.

Buildings	£4 0 0 to £16 0
Boilers	2 0 0 ,, 5 0
Steam and water piping and feed pumps	0 12 0 ,, 3 0
Steam-engines and condensers	3 0 0 ,, 11 0
Dynamos and switchboards	2 10 0 ,, 12 0 0

Total cost of power plant, not including buildings, £25 to £35.

Approximate Cost of Rolling-Stock.

Maximum traction trucks per set	£130
Ordinary bogie trucks per set	125
Standard four-wheel truck	70
Extra long truck	75
Double-deck car bodies	£220 to 300
Single-deck car bodies	210 ,, 265
Double-motor equipment, including resistances and controllers	260 ,, 320
Single-car motor, 15-50 h.p.	75 ,, 120

Cost of Track Laying.

Cost per mile of single track, 4ft. 8½in. gauge, 100lb. rails, wood or granite paving, including necessary electrical bonding	£5,500 to £6,500

Overhead Work.

Cost per mile, three-section tubular poles, standard brackets, 1/0 trolley wire.

Double trolley wire on side brackets	£1,100—1,400
,, ,, span wire	1,700—2,000
,, ,, centre brackets	1,300—1,500
Single trolley wire, side brackets	1,000—1,200
,, ,, span wire	1,600—1,800

with a population of 3,370,000, we find that the tramways carry the total population 260 times every year. For more details, and to show the rapid increase in traffic due to the electrification of the New York line, I would refer you to Tables I. and II., from which you will see that within the last five years the traffic has more than doubled. Taking into consideration the elevated roads and the various outlying districts which make up greater New York, we have a population of, in round figures, 3,500,000, and the tramway and elevated railway system carry 1,200 million passengers per annum, or, in other words, the total population of New York is carried once a day. Comparing these figures to what is obtained in London, we find that the tramway omnibuses and metropolitan lines only carry from 60 to 70 per cent. of the population of greater London every day, from which it is evident that the inhabitants of London do not move about as much as those of New York. This may possibly be attributed to the difference of temperament, and the different mode of conducting business. The total length of the London tramway system is in round figures 140 miles. A very important point, and one which has to be considered when comparing financial results obtained in England and America, is the average fare per passenger carried. From careful investigations which have been made, and from the figures given by Mr. James Dredge in an article of his which appeared in the March number of a journal called *Traction and Transmission*, it appears that the average amount paid per passenger on the different London transit systems is approximately 1½d., whereas in New York there is a uniform fare of 5 cents, or 2½d. It is evident from this that lines which would pay very well in America might not pay in England. Besides this fact, there is another one which has to be considered—viz., that the difference between the income and the actual expenses incurred by the working population of this country is a much smaller quantity than that which is at the disposal of the American workman, and that it is, therefore, probable that whilst the American will travel on an electric car for a very short distance, and whenever he gets a chance, the English workman will only travel when he is forced to do so.

It may be interesting to you to examine the probable costs of electric installation, and for this purpose I have prepared some tables, from which I will give some extracts. It will be evident, from a glance at Table III., that there is a very large variation of the capitalisation per mile of route. It is also evident that the smaller the system the less will be the cost per mile of route, provided the general conditions are favourable. It will be seen that the total expenditure varies from a minimum of £9,000 per mile of route in the case of Leeds and Halifax to respectively £56,000 and £84,000 in the case of Blackburn and Glasgow. As regards main lines, railways, such as the Liverpool Overhead and the London Tube, the capital expenditure must be very much heavier, and has reached, in the case of the Central London Railway, over half a million per mile of route. It may be stated that for estimating purposes the very best system, including power station, track, car, overhead work, feeders, etc., should be installed for from £15,000 to £20,000 per mile of route.

It may interest you to have an idea of how this total cost is made up, and for this purpose I have made out Table IV., from which you will see that the total cost of the power station can be safely taken at £30 per kilowatt installed, and that as regards the motorcars, a figure of £750 is a safe one to estimate on. For the permanent way with standard gauge and for heavy rails, such as are now nearly always adopted, £6,000 per mile of single track should be allowed. As regards the overhead construction, a figure of from £1,500 to £2,000 per mile of route is a safe one to estimate on. It must, however, be pointed out that all these figures can be used for roughly approximating costs and preliminary estimates only, as the conditions that obtain may considerably influence the total cost. It is only by a traction expert examining these conditions in the light of his experience that a real idea of the total capital which will eventually have to be expended can be obtained.

In investigating the question of how much money can be properly invested, it is necessary to ascertain the probable receipts and expenditure, and for this purpose I have prepared Table V. It will be seen that the population, in the cases given, is carried from 65 to 180 times a year. The receipts per head of population vary in the figures I give between 5s and 19s. per head. It will be seen that the receipts per mile of route vary between £2,200 and £7,300. The average fare per passenger varies from ·98d. to 1·62d., and the ratio of operating expenses to receipts from 49 per cent. to 85 per cent. I give, in Table VI., some figures for electric systems in the North of France, and it shows the rapid increase in traffic, and the decrease in ratio of expenses to receipts. Table VII. gives the increase of passengers carried in the case of some British electric tramways. It will be seen, for instance, that in the case of the Dover electric tramways, the passengers have more than trebled within the last three years. In this connection the figures as regards the city of Berlin, with a population of 1,810,000, may be of interest. The tramways, which have now been converted entirely to electric traction, carried 188,000,000 passengers in 1899, as against 306,000,000 in 1901.

Geneva Corporation, 1·0d.	Geneva Tramway Co.

TABLE XIV.—Leeds Corporation Electric Tramways. Year ended March 25.

	1900.	1901.
Total electric car receipts	£63,436 10 5	£133,449 11 5
Total car mileage	1,205,812	2,506,655
Receipts per car mile	12·62d.	12·77d.
Working expenses per car mile	5·97d.	6·49d.
Ratio of expenses to receipts	47·3 per cent.	50·8 per cent.
Cost of generation per B.T. unit	·82d.	·67d.
Total units generated	1,095,231	2,452,741
Supplied to arc lamps, shed lighting, etc.	59,682	190,251
	1,035,549	2,262,490

To give you an idea of the total amount of power which will have to installed, I have compiled Tables VIII., IX., and X. From Table VIII. the amount of power per car mile run can be ascertained. I may state here that, for rough estimating purposes, it is safe to take one Board of Trade unit per car mile for the conditions which generally obtain in this country. Tables IX. and X. show the amount of power installed in various German and British stations per motorcar operated, and per mile of route. For rough estimating purposes, it may fairly be said that approximately 10 kw. per car operated should, under normal conditions, prove sufficient.

The question of laying down a proper power station which will economically supply electricity for traction purposes is a very important one, and as the conditions that obtain in traction are entirely different from those which are met with in lighting work, a station eminently well designed for lighting purposes will generally be uneconomical for traction work. Electricity has been used commercially for lighting during the last 20 years, but the amount of power used for generating purposes would not be excessive, even if electric light were to supersede all other methods of illumination. The hours during which light is required every day are restricted, and the generating plant has to be idle the greater portion of the 24 hours, hence, even with the most careful study of the conditions that obtain, it is generally impossible to lay down a purely lighting plant which can produce electricity at all economically. The load on a station used only for lighting is very uneven, increasing from an insignificant amount most of the day to a very heavy demand for a few hours in the evening. Furthermore, the demand in winter and in summer is very different. and the maximum load in winter may attain proportions necessitating a plant which will lie idle most of the year. These conditions call for a large number of units of varying sizes, and it is often essential to have as small a first outlay as possible, as no economy in working can make up for the loss due to the capital which lies unproductive for relatively long periods, and for the waste due to maintaining steam and keeping the engines hot. This accounts for the heavy price which we have to pay for our electric lighting.

The extensions in the uses of electricity have naturally influenced the design of the power-house. Electric light was the first comer, and the plants laid down were as far as possible designed to fulfil the special conditions required in lighting. Thus, up till quite recently, with the exception of those who, like myself, have grown up with electric traction, practically all electrical engineers who were not telegraph men were lighting engineers. When electric traction began to come into use many stations were consequently designed as though intended for lighting. Indeed, it was not till electric tramways had been in operation some time that it was discovered by costly experience that what was right for electric lighting was out of place in traction work. A few moments' consideration will show that this result was inevitable by reason of the widely different demands. An electric lighting station, as we have seen, only works for a comparatively short time every day, and the load, though varying, is more or less steady. On the other hand, a traction plant works nearly continuously, and the load is scarcely ever steady for two consecutive minutes, due to cars starting and stopping. It is not an infrequent occurrence for a considerable number of cars to start simultaneously, thus putting a heavy overload on the generating units. The capital expenditure in the case of a traction installation is much greater than in the case of a lighting plant, and the long hours of working render the question of labour and fuel consumption of the very first importance. The practice is now coming in of designing stations to supply power for all purposes. When this is done at the commencement a very good station can be obtained, but where existing lighting stations are utilised the results are generally far from satisfactory. This appears to have been generally admitted, and except when a new station designed for traction and lighting work was being laid down, special plants have been put down. As examples I may give Glasgow, Leeds, Newport, etc. In the case where an old lighting station exists and power is required for traction work, in nine cases out of ten there is but one thing to do, and that is, to instal an entirely new plant, with the possible exception of boilers, for the traction work. This method may appear drastic, but it is the most economical in the end. The whole question of cheap power supply depends upon the station being properly laid out, so as to adequately fulfil the conditions required, and to secure as good a load factor as possible. It may be well to state here that by load factor is understood the ratio of the actual Board of Trade units measured at the switchboard in the power station to the amount which would be generated if the plant ran continuously at the maximum load which it is at any time called upon for. I have prepared Table XI. from an article which I have written for *Traction and Transmission* on the important question of the standardisation of power stations, and it will be seen from this table how much importance attaches to getting a high load factor.

It is evident that a lighting load by itself can under no conditions be favourable to a good load factor. It need hardly be pointed out that before proceeding to lay down the station the question of what load factor can be secured should be most thoroughly investigated.

It has been assumed by many that where free water power is available electrical energy can be generated very cheaply; this, however, is not always the case, as the capital required to harness the water power is often so great as to more than outweigh the saving in cost of production. Thus the electrical energy generated at Rheinfelden, at Zürich, and according to Mr. Kearshaw, even at Buffalo, costs more than it would if generated in the coalfields of England in large central stations by steam power. In the case of Zürich, the city engineer stated to me that notwithstanding the high cost of fuel (30fr. to 35fr. a ton), the only way to cheapen the cost of production was to increase the steam plant, which at the present moment generates electrical energy approximately at five-eighths what it costs to do it by water power. In this connection I have inserted a table of the price of selling electrical energy at Buffalo, as supplied from Niagara—it will be seen here that for amounts exceeding 80,000 units per annum the price charged is less than one-third; when we compare this to Table XIII., which gives some of the prices charged for electrical energy for traction purposes, it is remarkable that, under the high rates charged for electrical energy, electric tramways should be able to exist, except where they generate their own supply of power. Table XIV. gives some very interesting results of the Leeds tramways; it will be seen that the cost of power, which does not include sinking fund or interest, is very low, and that the results generally obtained are most satisfactory.

TRACTION SYSTEMS.

If we neglect the method of working tramcars by means of accumulators carried on the car itself, and which has been abandoned, there are three methods of operating an electric tramway all similar, in that current is generated at a central station and picked up by cars from a charged conductor. These systems of traction are known as: (*a*) the surface-contact system; (*b*) the underground conduit system; (*c*) the overhead trolley system.

Of the above, the last two are really the only practical methods in

Digitized by Google

existence: (*a*) In the surface-contact system a number of contact studs are laid in the track, each stud containing a switch by means of which it can be connected to the feeders leading from the generating station. The switches are designed to be only operated when the car is over them, this being done by an automatic device of which there are several varieties. Most of them are based upon the action of an electromagnet. When the stud is not covered by the car the connection between the stud and the feeder is broken, and the stud is dead and harmless. The car picks up the current from the stud by means of a slipper, which is made rather longer than the distance between the studs, so as to always make contact with one of them. This system, while perfectly correct theoretically, cannot be said to have been a success commercially. In Paris, a number of miles of track were equipped on this principle, but this system was found to be a complete failure. At present most of the lines in question are being converted to the overhead trolley system. There is only one example of the surface-contact system in England, and that is the experimental line which has just been put in by the Lorain Steel Company at Wolverhampton. The chief objections to the system are: (1) There is always a possibility that one of the automatic switches may fail to act, with the result that a stud will be left energised after the car has passed. (2) The studs must project to a certain distance above the level of the road, or else the collector on the car will not make contact without rubbing on the road; hence the studs must always offer some obstruction to ordinary traffic. (3) There is considerable loss through leakage from the studs. Practically the only thing that can be said in its favour is it obviates the necessity of overhead wires, with their possible dangers, without the terrible expense which is entailed by the construction of an underground conduit.

(*b*) In the underground conduit or slot system a conduit is constructed under the whole length of track, which conduit contains the charged conductors from which the car collects current. Communication between the car and the interior of the conduit is established through a narrow slot in the roof of the latter, which permits the collector carried by the car to move along the conduit, and thereby making rubbing contact with the conductors. The conduit can be constructed with a separate slot rail in the centre of the track, or under one of the track rails, which combines the offices of slot rails and track rail. The objection to this latter method is the difficulty experienced at points and crossings. This difficulty can, however, be overcome by deflecting the conduit to the centre of the track when points or crossings are encountered. The chief qualities required of a conduit are that it should have ample strength to resist any tendency of the slot to close, and that it should be easily cleaned out. The chief objection to the conduit system is its very heavy first cost, and the amount of disturbance caused to ordinary traffic by excavations which are necessary when building it. In the case of the conduit of the Metropolitan Street Railway of New York, the cost of construction came out at about £30,000 per mile of track. With conduits special work is very expensive, not only in first cost, but in repairs and maintenance owing to the additional number of slot points and crossings. The principal advantages of the system are: (1) an insulated return can be used, and the use of the track rails for this purpose dispensed with, thus avoiding bonding and any possibility of electrolysis; (2) it is not necessary to have overhead trolley wires, and thus any danger from their presence is done away with. The system is a thoroughly sound one, and has operated with perfect success commercially in several cities in the United States and Continent.

(*c*) The overhead trolley system is the one which is almost universally used for tramways and light railways, and it is very doubtful if engineers would ever instal any other system, except under special circumstances. Where such has been the case, however, it will usually be found that the reason why the overhead system was not employed was because the city authorities would not grant permission to erect overhead wires. There are very few real objections which can be urged against this system. Many people object to the trolley wire on the ground of its appearance, but this is a matter which is generally remedied by use and familiarity; after a short time it is scarcely noticed. It lacks one advantage of the conduit system—viz., the insulated return circuit—and special care in the bonding of the track is consequently necessary. Of course, it would be quite possible to have an insulated return circuit overhead, but the additional trouble and expense of stringing double trolley wires would completely swamp any slight advantage which might be gained therefrom. The real objection to the overhead wire is that there is always a possibility, however slight, of its breakage and fall. This, however, is a most infrequent event, and there are numerous safety devices to prevent the possibility of any serious accident should such a thing happen. On the other hand, the system has considerable advantages. It is much cheaper than conduit construction, and putting down the line does not cause nearly such disturbance in the streets. All the insulators, etc., are visible and accessible, thus facilitating and cheapening repairs and maintenance. Electric traction is having a considerable influence on the value of land, and considerable areas which before the advent of electric traction were a drug in the market are now being covered with houses. The reason of this is that the rapid transit facilities afforded by the use of electricity enables people to live at considerably greater distances from their work than formerly, and bring the outlying suburbs into much closer touch with the centre of business. It is in this expansion which is thus rendered possible that we may look for a solution to the ever-present "housing" problem.

Advantages of Electric Traction.—In the present state of affairs horse traction is quite inadequate to satisfactorily cope with the demands of a public who require to be carried quickly and cheaply from one place to another. Horses are slow and expensive and unsanitary, besides occupying a considerable amount of space, of which there is generally none too much. They can neither start nor stop quickly, but waste a considerable amount of time in doing either, especially the former. Thus, some form of mechanical traction is absolutely imperative, and of all forms of mechanical traction, electricity possesses the most advantages and desirable qualities. It is silent, clean, rapid, and economical, and when starting from a standstill full speed can be reached in very short time. It is this quality of rapid acceleration which rendered electric traction so specially suited for its work. It is only on comparatively rare occasions that a tramcar has a straight unimpeded run on which it can go at the maximum speed allowable—generally it is constantly being slowed up by the rest of the traffic. Thus on a crowded road a horse tramcar very rarely, if ever, runs at anywhere near its maximum speed, for by reason of the constant stops it never has time to get up speed before it has to slow down again. On the other hand, an electric tramcar being able to get up speed with extreme rapidity, can take advantage of every opening which presents itself, and maintain a very fair average speed under extremely difficult conditions. At one time cable traction was considered a serious rival to electricity, but practical experience has proved the superiority of the latter system, except under most exceptional circumstances. Where cable traction fails is in its rigidity—if by any cause traffic is stopped and the cars get "bunched" together, it is practically impossible to separate them again, as a cable car cannot make up time like an electric car. Another disadvantage is that it is quite possible for any gripman by making a mistake at points or crossings to practically wreck the whole system, or anyhow throw it into confusion for some considerable period.

Every part of an electric tramway has received the most careful study by those who are interested in the subject, and at the present day there is absolutely nothing experimental about the whole subject. A very large amount of experience has been gained, and everything has been standardised, so that there need be no hesitation as to the results which will be obtained through the installation of the ordinary direct-current system. It cannot be urged too strongly the importance of using the best material in every branch of the system, and equipping the line in a thoroughly sound and solid manner. The increased capital expenditure is more than counterbalanced by the smoothness of working of the whole system and the freedom from accidents, breakdowns, and such like. The power plant especially should be most carefully designed, so that, in the event of extensions being required in the future, these can be made in a proper manner, so that the enlarged station will work economically and conveniently as a whole, and not, as is sometimes the case, as two separate stations side by side.

In conclusion, I would like to say a word upon traction on main-line railways. Until it may be satisfactorily proved that electric traction will reduce the working expenses, it is certain that no railway company will adopt it unless it is forced to. I do not personally believe that any of the high-speed railways which are proposed to-day can be financially successful for long-distance travelling—it is expense rather than time which will be the determining factor. If railway companies can greatly increase their traffic by increased speed, they can do so at once without adopting electric traction. Thus at the present moment the Pennsylvania Railway Company are running trains at a schedule speed of from 70 to 80 miles an hour for long distances with heavy trains. We are by no means near the limit of speed of locomotives in this country. Thus at the present moment in France, the Northern Railway runs a distance of 184 miles in 3 hours and 10 minutes, as compared to a distance of 183½ miles between London and Manchester run in 4 hours 10 minutes. Capital is easily obtained when a profit is assured. Long-distance electric traction is no doubt a fascinating subject, but should not be at the present moment considered practical. I am convinced that we are entirely unprepared at the present moment to undertake the electrification of main lines, and it has not been shown that it would pay if it were done, and we really do not know how to do it. Given all the schemes which have been so far suggested, there are such serious objections that it is not probable that anyone will be found hardy enough to carry them out. On urban and suburban lines the case is entirely different, as I have so often said. There the traffic is ready-made, awaiting greater facilities which electricity alone can furnish. Here there is knowledge and experience to point the way in which the work should be carried out.

TUBE BILLS IN PARLIAMENT.

LORD WINDSOR'S COMMITTEE.

FRIDAY, MAY 9.

The Select Committee of the House of Lords of which Lord Windsor is chairman, sat specially to consider the competing Piccadilly schemes and the allied North-East London lines.

Colonel Yorke, chief inspector of railways under the Board of Trade, said it had been suggested that the companies should be compelled to deposit with the Board of Trade, or with some public authority, plans showing exactly the line along which the railway had been constructed, and that those plans should be open to inspection so that property owners and others interested might have an opportunity of ascertaining where the line was placed. There was no statutory obligation on railway companies to deposit plans with the Board of Trade, though certain plans were deposited under an arrangement between the engineers of the companies and the Department. The Department suggested, therefore, that some such clauses as that contained in the Waterworks Clauses Act and the Gas Clauses Act should be inserted in these Bills, providing that plans should be kept at the office of the undertakers and that they should be open to all persons interested at all times.

Mr. Pember, K.C., on behalf of the London County Council and other opponents, said he should certainly agree to that suggestion.

Digitized by Google

Continuing, **Colonel Yorke** said the attention of the Board of Trade had been drawn to the fact that on the Brompton and Piccadilly-circus line there was a curve of 3½ chains radius. Such a sharp curve would be regarded by him with considerable misgiving, and he should feel it his duty to take exception to it. Even if the radius were altered to 4½ chains, he should regard it as obligatory upon the Board of Trade to put a restriction on the speed of the train on passing over the curve. This would probably have an effect upon the train service run over the whole of the circuit. It seemed to him the tendency of the motorman would be to approach that curve at a higher rate of speed than was desirable. He thought a five-chain curve was the smallest curve that was advisable. If such a curve as 3½ chains were authorised he should consider it incumbent to advise the Board of Trade to limit the speed to 12 miles an hour, and to 13 or 14 miles an hour with a curve of 4½ chains. Then in the case of reverse curves there should be a length of straight line interposed between the two. As to the dimensions of the tube, the Board of Trade would insist on the larger tunnels only in those lines that were now taking parliamentary powers for the first time. He thought that a maximum size of tube might be fixed, up to which the companies might work, and beyond which they might not go. The shape of the tunnel might be left to the Board of Trade. It had been assumed hitherto that tubes must be invariably circular in section, but it had occurrred to him that there would be conveniences and advantages if they were constructed similarly to those of ordinary railway tunnels. There was nothing in the Bills before the committee to render it absolutely obligatory on the companies to make a circular tube.

Mr. Littler, K.C., on behalf of the Brompton and Piccadilly-circus Railway, said they were prepared to place themselves unreservedly in the hands of the Board of Trade as to construction and method of working.

The opposition to the proposed North-East London and City and North-East Suburban Railways was continued.

Mr. J. F. Gooday, general manager of the Great Eastern Railway, expressed the opinion that the proposals for these lines were quite impracticable financially. He estimated that the construction of the railways would take a net sum of £73,000 from the Great Eastern Company.

Mr. Grinling, traffic manager of the Great Northern Railway, said that the service of the Great Northern Railway, supplemented by the arrangements entered into with the Great Northern and Strand and the Great Northern and City underground railways, was sufficient for the needs of the districts to the north and north-east. The proposed railway would have to meet the competition of the North London, Great Eastern, and Great Northern Railways, and the tramways and light railways of the Middlesex County Council.

The committee adjourned.

MONDAY, MAY 12.

Further evidence was taken on the opposition to the North-East London and City and North-East Suburban Railways.

Mr. Dunn, general manager of the North London Railway, expressed the opinion that by the interchanges it was proposed to have between the North London Railway and the lines which had been authorised this session and in previous years, the traffic from the north to the west and east would be amply served. To pay 4 per cent. interest on its capital of £5,000,000, the proposed North-East London line would require to earn £432,713 per annum. This would necessitate the carrying of 151,334 passengers per day, which would involve the running of 631 trains with 240 passengers in each train. He believed it was absolutely impossible to obtain such an average.

Mr. Pember, K.C., then addressed the committee on behalf of the District Railway and the Great Eastern Railway Companies against the proposals of the combined companies for lines from Hammersmith on the west to Waltham Cross and Southgate on the east and of the Central London Railway. The problem was this: were the existing lines of the District Railway, plus their authorised deep-level line, the authorised Brompton and Piccadilly-circus line, and its proposed extensions to Charing Cross and Holborn with the lines of the Great Eastern and other existing line on the east and north-east of London, capable of doing all, or very nearly all, that the proposed rival lines would do? He suggested that the committee should sanction an additional expenditure of £2,404,000, which would be required to link up the authorised lines and complete the route he had sketched out, rather than the £7,000,000 which would be involved in the construction of a new railway from Hammersmith to the City.

Lord R. Cecil, K.C., next addressed the committee on behalf of Mr. Walker, of Southgate, in opposition to that portion of the proposed North-East London Railway which ran from Palmer's Green to Chase Side, Southgate.

The **Chairman** said the committee were agreed that they did not require to go further into the opposition to the bit of line between Palmer's Green and Chase Side, because, on the promoter's own case, they did not think the preamble of that portion of the Bill had been proved.

Sir A. Binnie, who was called by Mr. Frere, on behalf of the Tallow Chandlers' Hall, said he had been consulted upon this point, and he had come to the conclusion that, owing to the age of the Tallow Chandlers' Hall—it had been erected more than 150 years ago—and the nature of the foundations, there would be a considerable risk if the railway were constructed as proposed.

The committee here held a consultation, as a result of which

The **Chairman** said they were agreed that that part of the preamble of the City and North-East Suburban Railway Bill which related to the line running from Whitechapel to the Mansion House under the District Railway had not been proved. The committee wanted to know whether the northern portions of the proposed line would now be proceeded with.

Mr. Page, K.C., said the promoters would like to consider the matter, and he would inform their lordships of the decision arrived at next day.—The committee adjourned.

TUESDAY, MAY 13.

On the committee resuming their sittings, the **Chairman** announced that the committee did not consider it necessary to call for any opposition to the Bill of the Charing Cross, Hammersmith and District Electric Railway Company, as they did not consider the preamble proved.

Mr. Page, K.C., for the City and North-East Suburban Railway, said his clients had considered the declaration of the committee that the preamble of this Bill was not proved as far as it related to the construction of the line from Whitechapel to the Mansion House, and they had determined to proceed with the rest of their scheme to construct a line between Whitechapel and Waltham Cross. The promoters had every hope that next session powers would be given to them to construct some further railway bringing them to the heart of the City from Whitechapel.

Mr. Littler, K.C., hoped the committee would not listen to the suggestion that they should pass an imperfect scheme on the strength of something coming forward next session.

The **Chairman** said they would hear the opposition to the rest of the scheme.

Mr. Balfour Browne, K.C., for the Piccadilly and City combined companies, said the committee would remember that the relations between the Piccadilly and City Company and the City and North-East Suburban Company were so close that they had promised to find two-thirds of the capital for the line to Chingford. He desired to state that, truncated as it had become by their lordships' decision, they no longer regarded the line as part of their scheme.

Mr. Littler contended that this was now a scheme with no financial backing.

Viscount Knutsford remarked that the committee had not gone into the finance of the promoters except as part of a combined scheme.

Mr. Page said that, with regard to finance, it was obvious that their position had been changed very much by the committee's decision and Mr. Balfour Browne's statement. He would ask the committee to defer their decision on the question of finance, at any rate, until to-morrow.

The **Chairman** said the committee were agreed that, the promoters' case having been closed, they could not reopen it. They did not wish to call for further opposition to the northern portion of the North-East Suburban line, but they were ready to hear Mr. Page in reply to-morrow morning before they actually came to a decision. The committee would not call upon the opposition.

Mr. Littler then addressed the committee on behalf of the Metropolitan Railway Company in opposition to the North-East London line, which proposed to run under the existing joint railway of the Metropolitan and District from the Monument to Cannon-street for a distance of 25 chains.

Mr. Clode, for the South-Eastern and Chatham Railway Companies, stated their objections to the proposal of the North-East London Railway to come under the line at Ludgate-hill. The interchange station at Ludgate-hill offered by the Central London Railway, which did not propose to go under the South-Eastern and Chatham line, was infinitely superior to that offered by the North-East London Railway.

Mr. Balfour Browne said he would submit a clause to provide for giving compensation for damage if it was caused by the construction or the working of the railway during two years. They would provide no compensation to anybody whose property had been paid for or who had been paid for an easement. The clause would also suggest a special tribunal—not the ordinary court of arbitration under the Lands Clauses Act—to settle questions of damage.

The **Chairman:** If such a clause were provided it could form the basis of consultation with Lord Ribblesdale and the members of his committee.

The committee adjourned.

WEDNESDAY, MAY 14.

The committee further considered the competing Piccadilly schemes.

Mr. Balfour Browne, K.C., said the committee had been informed on Tuesday that the promoters of the City and North-East Suburban Railway had determined to proceed with their line from Whitechapel to the north notwithstanding that their lordships had rejected that portion of the scheme which ran from Whitechapel into the City. They did not feel, however, that they would be justified in going on with a truncated scheme, and he proposed to ask the leave of the committee to withdraw his Bill, which was granted.

Mr. Balfour Browne then addressed the committee on behalf of the North-East London Railway, which proposes to run from Ludgate-circus to Palmer's Green, the continuation from Palmer's Green to Chase Side, Southgate, having been disallowed. The line provided a through route from the crowded parts of the City to the country. The combination, of which the North-East London Railway formed a part, had been severely criticised; but it was a combination seeking to give the public something it had not got, and was opposed by a railway "ring," which gave its support to the Central London proposals because they wanted to fence themselves in from any competition with their suburban traffic.

The **Chairman** said the committee had given careful consideration to the present position, and they had finally decided to go on with the opposition to all the Bills. They would first of all take the opposition to what had been called the Morgan group, then to the Brompton and Piccadilly-circus Railway, and, finally, to the Central London Railway. When that opposition was finished, the committee would call for the advice of the London County Council and the Corporation of the city of London upon all the schemes before them. That would be followed by the speeches of counsel for the various promoting Bills. The committee had also come to the conclusion that they could not hear the opposition of landowners until they had decided what Bills should not proceed.

Lord R. Cecil, K.C., said he had been asked by Lord Ribblesdale

Digitized by Google

to mention that Mr. Moon, K.C., had submitted a general clause for the protection of landowners, and that Lord Ribblesdale had also suggested a clause which might form the basis of argument and consultation. It was understood, however, that no clause should be inserted in any of the Bills before Lord Ribblesdale's Committee until there had been an opportunity of discussion with their lordships' committee of the proposed general clause.

The **Chairman** said he would take an opportunity of consulting with Lord Ribblesdale with a view to the adoption of the same course in both committees.

Sir Douglas Fox, joint engineer to the combined undertaking of the Piccadilly and City and London United Electric Railways, recalled and examined with reference to the engineering features of the Brompton and Piccadilly-circus and the Central London Railways, said his strong objection to the former was to the connecting link with the deep level of the District Railway between Piccadilly-circus and Charing Cross. He should say that that piece would be an unworkable line. The effect of the proposed junction at Piccadilly-circus would be to put four tunnels one above the other. The junction at the Charing Cross end was about as bad as it could be. As to the Central London Railway proposals, he considered that a closed circuit, especially in the centre of London, was most objectionable from both an engineering and a public point of view. The traffic coming from outside the circle must change, and when the trains reached the interchange stations they were invariably crowded.

Mr. F. G. Thomas addressed the committee in the interests of the Metropolitan Railway Company against the proposals of the Central Railway and the combined Piccadilly and City scheme. Their main objection to the Central Railway extension was that it established a new east and west competition with their existing line between Hammersmith and the City. This was not an appropriate time to expose the Metropolitan to new competition, in view of the expense of the electrification of the Metropolitan and the District, which would be effected within the next 18 months.

The committee adjourned.

LORD RIBBLESDALE'S COMMITTEE.

FRIDAY, MAY 9.

The committee presided over by Lord Ribblesdale proceeded with their consideration of the City and Crystal Palace Railway Bill.

Mr. S. Sellon, engineer to the British Electric Traction Company, recalled, stated with the authority of the chairman of his company that they were prepared to give substantial assistance towards the carrying out of the undertaking.

Mr. F. Schenck, chairman of the Crystal Palace Company, said if the Bill passed he would be prepared to find £1,000,000.

After some further financial evidence had been given, the committee decided that they would not proceed further.

The Bill was therefore rejected.

The committee next considered the Great Northern and City Railway Bill.

Mr. Moon, K.C., described the proposal as a short extension of an authorised line rapidly approaching completion, which he hoped would be opened in the course of a year. It started under the Great Northern Station at Finsbury Park, where there would be an interchange station, and the present terminus was provided for at Finsbury-pavement. The Bill would empower the company to erect a generating station at Shoreditch, to construct a passenger station at Highbury, and enlarge the station at Finsbury-pavement, but the main object was to extend the line from Finsbury-pavement to near the Bank.

Sir C. Scotter, chairman of the company, and **Sir H. Oakley**, director of the Great Northern Railway Company, gave evidence in support of the proposals.

Sir Douglas Fox gave evidence from an engineering point of view.

Mr. G. C. T. Bartley, M.P., **Mr. C. Hay, M.P.**, and **Mr. J. Crump**, mayor of Islington, expressed opinions that the proposed extension would be of much public convenience.

The committee adjourned.

MONDAY, MAY 12.

The committee proceeded with consideration of the Great Northern and City Bill.

Sir Douglas Fox, recalled, said the line would not approach nearer to the Bank of England than the southern end of Moorgate-street. The nearest shaft would be 30ft. away. It was proposed to construct five shafts between the corner of the Bank and the end of Moorgate-street for the purpose of lifts.

The **Chairman** said the committee would consider the question of inserting the Bank of England clause in the Bill. In reference to the model clause that had been mentioned earlier, it was not his intention that the appeal to a special tribunal should extend to those who had their right under the Lands Clauses Act. The clause to be submitted by the promoters might prove a basis of agreement.

Mr. Moon, K.C., said the promoters were willing to give a two years' clause, but if, as the result of the consideration of Lord Windsor's Committee, a longer period than two years should be agreed upon, the promoters would amend the clause before the Bill reached the other House.

Mr. Littler, K.C., said the City Corporation viewed this project with disfavour, because the short distance of about 300 yards by which it was proposed to extend the line did not justify the enormous expenditure upon it.

Mr. Freeman, K.C., stated that arrangements were in progress that would render opposition to the preamble unnecessary on the part of the Metropolitan Railway Company.

The committee declared the preamble of the Bill proved, and that the promoters must understand that a clause must be inserted for the protection of property owners, and upon this and in reference to a Bank of England clause, the chairman would consult with Lord Windsor and the Chairman of Committees.

The committee then took up the North-West London Railway Bill, which **Mr. Baggallay, K.C.**, explained was for the purpose of granting an extension of time for three years for the construction of a tube line from the Marble Arch to Cricklewood under the Edgware-road, authorised in 1899. It also asked for sanction to an enlargement of the tubes from 12ft. 6in. to 13ft. diameter.

Mr. Scott Russell, a director of the company, gave formal evidence, and the preamble was declared proved.

Several points raised by the petition of the London County Council referring to the building line, workmen's trains, rehousing of the working classes, and ventilation, were left over to be dealt with on clauses.

The committee adjourned.

TUESDAY, MAY 13.

The committee proceeded with consideration of a number of clauses proposed by the London County Council for insertion in the North-West London Railway Bill. Counsel asked that a provision should be inserted for reducing workmen's fares to 1d. single and 2d. return, and for slightly extending the time within which workmen's tickets can be used.

The committee rejected the amendment.

The promoters agreed to a provision enabling employers to purchase batches of workmen's tickets for distribution.

The Great Northern and Strand Bill was next considered.

Mr. Balfour Browne, K.C., explained that the Bill was for the purpose of extending the time for authorised works. The Act authorised construction of a tube railway between Finsbury Park and the Strand.

The preamble was declared proved.

In discussion of the clauses in the Great Northern and City Bill,

The **Chairman** said the committee were of opinion that what was known as the Bank of England clause should be inserted, with a distinct understanding that it was for the protection of the Bank of England as a special building. The clause did not form a precedent for other buildings.

Mr. Moon, K.C., submitted the terms of a clause the promoters were willing to insert for the protection of persons whose property might be damaged by the working of a tube railway. The clause provided that if before the expiration of two years from the opening of the railway any damage should be caused to his property the owner would have the right of compensation, in addition to any remedy he would have under the existing law.

The **Chairman** read the heads of a clause such as he had in mind as a model clause for insertion in all these Tube Railway Bills. It would provide that if at any time within two years after the opening of the railway for traffic an owner or lessee of land or building complained of damage or annoyance from construction or working in respect to which he could not claim compensation under the Lands Clauses Act, such complaint should be referred to an arbitrator, not being an engineer, to be appointed by the Board of Trade. The arbitrator might be assisted by two engineers, if necessary, and have power to award compensation. He would like to see something drafted to carry out these heads as a model clause, subject to consultation with Lord Windsor and the Chairman of Committees.

The committee eventually decided that the insertion of a clause dealing with the question should be deferred until after Whitsuntide and after consultation with Lord Windsor's Committee.

The committee adjourned.

WEDNESDAY, MAY 14.

The committee practically concluded consideration of the group of Tube Bills allotted to them. The sitting was largely taken up with the settlement of the clauses of the Great Northern and Strand and Great Northern and City Bills, the only new measure being the Baker-street and Waterloo Bill.

Mr. Page, K.C., in opening the case for the Bill, said its principal object was to obtain an extension of time for the purchase of lands and construction of works. He believed that one tunnel from Waterloo to Oxford-street was absolutely finished, and the other was well up Regent-street. Up to December, 1901, practically £1,000,000 had been expended. In March of the present year the contracts of the London and Globe in regard to the line were transferred to the Metropolitan District Electric Traction Company, of which Mr. Yerkes was chairman, and they would be taken over by the Underground Electric Railways Company of London, which had a capital of £5,000,000. Counsel added that the work would be carried out as rapidly as possible, and would shortly be completed.

The preamble of the Bill having been approved,

Mr. Perks, M.P., stated that 60 per cent. of the tunnels had been completed, and all the stations were constructed or in course of construction. He asked the committee not to make any alterations in the fares already sanctioned, as the whole of the fares on the District and allied lines would have to be revised, and any decision by the committee might prejudice that question. He understood that the District Railway should come to Parliament next year for sanction for the new scheme of fares.

The committee accepted the assurance, and left the question of fares untouched. Clauses were then agreed to, and the committee rose.

PHYSICAL SOCIETY.

At the ordinary meeting of this society held on May 9, Prof. S. P. Thompson (president) in the chair,

Dr. P. E. Shaw exhibited a "**Simple Electric Micrometer.**" Two years ago Dr. Shaw described an instrument with which he measured

Digitized by Google

very small lengths by the application of electric contacts, and the micrometer shown was a simple form of the original apparatus. A screw, fitted with a milled head, turns in a fixed nut, and its lower end presses upon the extremity of the long arm of a lever. A metal point is attached to the short arm, and the distance through which it moves, on turning the milled head, can be deduced from a knowledge of the pitch of the screw and the ratio between the arms of the lever. In using the instrument, this point is always brought up to a metal surface, and the contact is accurately determined by the telephonic arrangement described in connection with the original micrometer. Dr. Shaw illustrated the use of the instrument for measuring small lengths by describing the following eight applications to ordinary laboratory measurements: (1) The measurement of the thickness of plates, films, or fibres. The object is placed between two metal plates. The point of the micrometer is adjusted to touch the top plate and the reading taken. The object is removed, the point is again brought into contact with the top plate, and the difference between the readings in the two cases gives the thickness of the film. (2) The determination of Young's modulus by the elongation of a wire. Dr. Shaw described experiments on two wires, each 2½m. long, hanging side by side, one of copper and the other of steel. The wires terminated in horizontal platforms, to which the stretching weights were attached. The base of the instrument rested on one platform, while depressions of the other due to loading were measured. In this way any error on account of the bending of the beam from which the wires were hung was eliminated. (3) The determination of Young's modulus by the bending of a beam. (4) The determination of simple rigidity by a static method. Observations were made upon a rod held horizontally by rigid wall brackets. One end of the rod was fixed, and the other held in position by a pin pressed into a hole in the end of the rod. From this end an arm projected outwards. Weights were applied to the extremity of this arm and the twist measured by observing with the micrometer the movement of the end of the arm. (5) Application to the extensometer. (6) Measurement of thermal expansion. (7) Microscopic measurements. In measuring the diameter of a capillary tube the cross wire of the microscope is made to touch one side of the tube, and the point of the micrometer is brought into contact with the metal stage. The stage is then moved by a screw until the cross wire comes to the other side of the tube. The micrometer point is moved into contact again, and the difference in the readings gives the diameter of the tube. In this measurement the full magnifying power of the microscope is utilised, and the work of moving the stage is performed by a rough screw. (8) The direct measurement of the wave-length of light. Newton's rings are formed by a convex lens and a piece of plate glass. The convex lens is fixed to the short arm of the lever, and the distance through which it must be moved to cause a certain number of bands to appear at the centre gives a means of calculating the wave-length of the light employed.

Prof. Everett said the apparatus combined fineness and accuracy of measurement, and expressed his interest in the determination of distances with the microscope.

Mr. R. J. Sowter asked if any special precautions had been taken to prevent deformation in the instrument. If not, then it was optimistic to assume that one or more multiplying levers could be used to measure lengths of the order of a millionth of a millimetre with any physical accuracy, assuming the multiplication of measurement to be according to the law of the lever, as Dr. Shaw apparently did.

Mr. W. Watson said that, in determining the wave-length of light by Newton's rings, it was necessary to measure from the knife-edge of the lever to the centre of the rings. The accuracy of the experiment was limited by the difficulty in judging the centre. The variation of the temperature of the air would distort the lever and produce errors. In reference to the experiments on Young's modulus using two wires of different material, he said that no precautions had been taken to procure a steady temperature, and pointed out that variations in temperature would affect the two wires unequally. In the experiment on the torsion of a rod the twisting had been produced by an unbalanced force. The other arm of the necessary couple must therefore have been unsatisfactorily supplied by the friction of the pin which held the rod in position. In measuring the diameter of a capillary tube with extreme accuracy, it was necessary to have a normal section, which was somewhat difficult to obtain. Dr. Shaw apparently considered the instrument as suitable for laboratory work. If it was for students, it was unnecessarily elaborate, and if for obtaining accurate measurements, there were objections and uncertainties which should be investigated. Mr. Watson said that a similar form of micrometer had been described by Mr. H. C. Russell and used in the observatory at Sydney.

Mr. J. M. Barr said that as errors would be introduced by variations in temperature, it might be advisable to make the instrument of a nickel-steel alloy with a small coefficient of expansion. He asked if the knife-edges and screws used were good enough to give the same reading twice, and said he thought the limit of physical accuracy could be obtained by using a single disc on a screw calibrated throughout its length. He considered $\frac{1}{10000}$in. to be about the limit attainable by such methods.

Dr. Shaw, in reply, said the main justification of the apparatus was in the consistency of the results given by it; these were excellent, as the tables given in the paper showed. The method had been shown to be much more accurate than those in general use. As to the contention that the apparatus, while too sensitive for laboratory practice, was not sufficiently so for research on length changes, he pointed out that the accuracy of all measuring instruments was always on the increase, so that laboratory methods which were considered good recently would not necessarily suffice in the immediate future. Why be content, even for teaching students, with measuring to $\frac{1}{10}$mm. by the microscope when with the simple electric micrometer we get, with little trouble, to $\frac{1}{1000}$mm.? Dr. Shaw knew nothing of the prior publication in Australia mentioned by Mr. Watson; if there were such a method introduced years ago, it was all the more astounding that Mr. Russell and his successors should have allowed such an excellent idea to lapse and remain immature and unknown. Some speakers had suggested that uncertain deformation of the levers might occur during an experiment and vitiate results; but a new strain implied a new stress, and, unless a definite change occurred in the forces of the system, we could not suppose a change in deformation. A like answer was given to the criticism that the levers might expand under heat during a measurement. Why, if sufficient time has elapsed to allow the system to attain temperature equilibrium, should anyone postulate expansions without indicating a new or irregular source of heat? Most of the above supposed evils, of course, existed, but they were of small account. As with every good apparatus ever produced, if ordinary and suitable precautions be taken these errors were reduced to a lower of importance, and could be neglected. In conclusion, the method had been firmly established in University College, Nottingham, and had superseded other apparatus. It would no doubt spread and become general.

Papers on "The Conservation of Entropy," by Mr. J. A. Erskine, and "Rational Units of Electromagnetism," by Signor G. Giorgi were postponed, and the society adjourned until May 23.

FORTHCOMING EVENTS.

FRIDAY, MAY 16.

Institution of Mechanical Engineers.—Annual conversazione.

Royal Institution.—At 9 p.m., Sir Robert Ball on "The Nebular Theory."

WEDNESDAY, MAY 21.

Institution of Electrical Engineers (Students' Section).—At 7.30 p.m., annual general meeting. Paper: "Some Notes on Recent Continuous-Current Dynamo Design," by Mr. F. J. Hiss, jun.

Royal Meteorological Society.—At 4.30 p.m., ordinary meeting. Papers: "Report on the Wind Force Experiments on H.M.S. 'Worcester' and at Stoneness Lighthouse," by Mr. W. H. Dines and Captain D. Wilson-Barker; "The Cornish Dust Fall of January, 1902," by Dr. Hugh Robert Mill.

THURSDAY, MAY 22.

Institution of Electrical Engineers.—At 8 p.m., at the Society of Arts, annual general meeting.

FRIDAY, MAY 23.

Physical Society. — At 5 p.m., ordinary meeting. Papers: "On the Ebullition of Rotating Water: a Lecture Experiment," by Mr. T. C. Porter; "The Conservation of Entropy," by Mr. J. A. Erskine; "Rational Units of Electromagnetism," by Mr. G. Giorgi.

APPOINTMENTS VACANT.

Resident Electrical Engineer, St. Annes-on-Sea Urban District Council, £175 per annum, May 20. Full particulars in our advertisement columns.

Assistant Distributing Engineer, London, £140 per annum, May 21. Full particulars in our advertisement columns.

Draughtsman, for electrical measuring instrument department, G Dept., Ferranti Limited, Hollinwood, Lancashire. Full particulars in our advertisement columns.

Switchboard Attendant, Eccles Corporation electricity works, £62 per annum, May 24. Full particulars in our advertisement columns.

Borough Electrical Engineer and Tramways Manager, Newport (Mon.) Corporation, May 31. Full particulars may be obtained from the town clerk.

First-class Assistant in drawing office (Manchester), switchboard work. Full particulars in our advertisment columns.

Draughtsman, Leicester Corporation borough engineer's office £135 per annum, May 27. Full particulars in our advertisement columns.

NEW COMPANIES REGISTERED.

New British Arc Lamp Company, Limited.—Capital, £10,000. Objects: to adopt an agreement with the Davy Electrical Construction Company, Limited, and generally to carry on the business of electricians, electrical engineers, mechanical engineers, producers and suppliers of electricity, etc.

Provincial Electric Construction Company, Limited. — Capital, £3,000. Objects: to acquire the business of a general electrician and contractor as carried on by G. F. Rimmer at 19, Minster-buildings, Church-street, Liverpool; to adopt an agreement with the said G. F. Rimmer; as manufacturers of and layers down of cables, wires, etc.

Haskew Walton Company, Limited. — Capital, £10,000. Objects: to adopt agreements with Haskew and Walton, A. J. Ash, F. J. T. Haskew, and A. R. Walton, to acquire and turn to account patents relating to the manufacture of welded tubes, and generally to carry on business as electrical and mechanical engineers, etc.

THE INCIDENCE OF THE FACTORY ACT.

Legislation is generally for the protection of the wicked and the damnification of the good. The Factory Acts are good examples of this state of things, and also of the grandmotherly legislation that assumes humanity unable to take care of itself. Almost every legislative act of interference with trade and manufactures means an increasing weight of millstone round the necks of business men in this country. The Factory Act of 1901 seems to lie heavily upon some of the electrical enterprises of to-day, hence the action of the Institution in calling the conference on Monday last—a report of which appears elsewhere in this issue. To those who understand the working of existing central and sub-stations, some of the clauses in this Act appears ridiculous, and though the Home Secretary may upon representation rescind them in certain particulars, there is trouble and annoyance in getting such recision. But the particular phase of the question to which we wish to direct attention is as regards the old-fashioned system of apprenticeship. Is not legislation mainly answerable that real apprenticeship has gone out of fashion? A few years ago youths were taken into works at an age when their limbs were supple and their minds free, and put through the mill from floor sweeper to foreman. Their responsibilities were increased as their knowledge and experience of the work increased. The result was good, and was generally acknowledged to be good. Assume at the present time that parents desire to apprentice their children to certain branches of electrical work. They certainly could not do so in the manner of years gone by, and if they did and could the result would hardly spell success. If the Legislature stands in the way and forbids the giving of minor or semi-responsibility to a lad of sixteen to eighteen years of age who has had experience, and whose knowledge of the matter is sufficient, in cases where probably such lads are the best possible persons to fit the position, then masters and men ought to combine to compel better counsels to prevail. Take a specific case—the hours during which lads may be employed. According to the present law it is exceedingly difficult to see how lads can gain real experience in central-station working. The time to try the capacity of any one employed in the station is the time of full load, and especially when the whole apparatus is fully loaded because of unfinished extensions and too many lamps wired. If a youngster is not to see the troubles which arise and how they are successfully combated till after eighteen years of age, a large part of his apprenticeship time must be wasted. Perhaps the Legislature has run away with the view that electrical apprentices should commence their work at the age of eighteen, and in order to become a good and efficient station hand an experience of three years only is needed. Putting, however, all such questions on one side, the artificial limitation of hours of work and days worked is a mistake when the demand is one which never ceases. You have an easy and acceptable occupation for a lad of seventeen years; the circumstances of the case often only warrant the employment of one lad per shift of eight hours, yet the lads are precluded from taking meals on the premises, or working holidays or Sundays—so that other arrangements must be made, usually increasing the expense and decreasing the efficiency. It must be remembered that the maximum demand in central stations comes at a time required by a public over which the management has no control—in most factories the management determines the hours of labour—hence restriction to hard-and-fast hours in electrical work is of

Digitized by Google

greater importance, and handicaps the organisation most heavily. We object as much as the most emotional sentimentalist to overwork or long hours We say, do all that is possible to build up physical robustness in our youths, but surely there can hardly be named a lighter or healthier occupation than that in which many lads have been employed by some of the electrical companies. The agitation being given to this matter by the Institution and cognate associations will, we hope, lead to a reconsideration of the whole question, especially as regards the electrical industry.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

LONDON COUNTY COUNCIL LAMPS.

We have received the following letters from Mr. W. Davenport, the secretary of the National Electrical Manufacturers' Association :

SIR,—I enclose copy of correspondence with the London County Council, which may be of interest to the electrical world.—Yours, etc., W. DAVENPORT, Secretary.

[COPY.]

G. Gomme, Esq., clerk of the London County Council,
Spring-gardens, S.W.

Dear Sir,—Your letter of Jan. 9 last, asking for tenders for electric lamps, together with your specification for same, is before me. In this specification you stipulate that the lamps shall be of English make, and you further bind those who tender to certain labour requirements which can only apply to goods made in this country.

We are informed that you have accepted the tender of the Brush Electrical Engineering Company, whose lamp works are in Vienna.

I am instructed to draw your attention to this, and to ask your assurance that English-made lamps only will be accepted.—Yours faithfully,

(Signed) W. DAVENPORT, Secretary.

The National Electrical Manufacturers' Association,
Ridler-place, Holland-street, Blackfriars,
London, S.E., April 16, 1902.

[COPY.]

London County Council, County Hall,
Spring-gardens, S.W., 23rd April, 1902.

Sir,—I am directed to thank you for your letter of the 16th inst., and to say that the Council were aware that the lamps supplied by the Brush Electrical Engineering Company would be foreign made. On the next occasion of inviting tenders for electric lamps firms will be asked to send in two quotations, one for English-made lamps and the other for foreign-made lamps.—I am, Sir, your obedient servant,

(Signed) G. GOMME, Clerk of the Council.

The Secretary of the National Electrical Manufacturers' Association, Ridler-place, Holland-street, Blackfriars, S.E.

INSTITUTION OF ELECTRICAL ENGINEERS

At the ordinary general meeting on May 8, the following were the candidates balloted for :

Members.—T. J. Fleming, 25, Victoria-street, Westminster, S.W.; S. W. Hulse, Union Elektricitats-Gesellschaft, Berlin.

Associate Members.—H. D. B. How, Royal-chambers, Park-place, Cardiff; A. J. Fippard, Broad Sanctuary-chambers, Westminster, S.W.; J. P. Kemp, 4, New York-street, Manchester; H. C. King, Sunnydene, Elm-road, Wembley; A. F. Rock, Electrical Department, North Staffordshire Railway, Stoke-on-Trent.

Associates.—W. S. Entwistle, Poldhu Hotel, Mullion, South Cornwall; C. H. Haddrell, 16A, Soho-square, W.; A. N. Hazlehurst, 85, London-road, Leicester; R. M. Leonard, 19, Ludgate-hill, E.C.; A. Mansfield, Royapmain, Madras; C. F. B. Marshall, 34, Lexden-road, Colchester; F. L. Moysey, 78, Wellmeadow-road, Catford, S.E.

Students.—J. Gray, Middleton House, Dalry, Ayrshire, N.B.; P. H. Harding, Oreston, Granville-road, Sidcup; M. A. Stoppoloni, 39, Perrymead-street, Parson's Green, S.W.; W. L. Turner, Purley Chase, Atherstone, Warwickshire.

THE FACTORY ACT OF 1901.

A conference of representatives of branches of the electrical industry which are affected by the provisions of the last Factory and Workshops Act was held in the rooms of the Society of Arts, Adelphi, on Monday afternoon under the auspices of the Institution of Electrical Engineers. Mr. W. E. Langdon was in the chair, and about 50 delegates attended from different parts of the country, representing both municipal and private electrical undertakings. Several of the railway companies also sent delegates.

The SECRETARY (Mr. W. G. McMillan) having read the notice convening the conference,

The CHAIRMAN said he might state at once that the object in calling this meeting of representatives of the industry had not been in any way to cast reflections on the Home Department or the Government. They were there merely to consider the incidence of the Factory Act of 1901 in its application to the generation of electricity. They knew that the State had a duty to perform, but at the same time the interests of the industry must be protected. This was a commercial nation, and there could be no doubt but that the electrical industry was destined to be of the greatest service to the commercial and industrial productions of the country. It was very desirable, therefore, that the industry should be relieved of all possible impediments which might in any measure restrict its advantageous application to the manufactures or to the industries of the country. Our merchants and manufacturers had to compete with the productions of other countries, and electricity was being applied in those countries to industrial production with the greatest advantage. They desired, therefore, that this country should not be subject to greater penalties or restrictions in making use of this new application of power in the interests of the community. Hence the desire of the Institution of Electrical Engineers to call together this conference. The views which he had expressed were not, he believed, quite foreign to the Home Department, and it was in that sense that he desired to conduct the consideration of the question that afternoon. As to the Act itself, those provisions which applied to non-textile productions and to some other branches of manufacture might be extremely satisfactory, whereas in their application to the generation of electricity they might be wholly unnecessary. Much, of course, must depend upon the way an Act of this sort was administered, and he could not but think that any views expressed by a representative conference of this kind would have a very powerful influence on the determination of the regulations which had yet to be drafted. They had to bear in mind that the Act, as it stood, was complete, although it was in the power of the Home Secretary to rescind its action in certain particulars. Some correspondence had passed between the secretary and representatives of generating stations with reference to the employment, for instance, of young persons—*i.e.*, youths under 18 years of age—which employment was restricted to certain hours and to other conditions, all of which, he might say from his own experience, were somewhat prejudicial, and tended to create dissatisfaction on the part of other members of the working staff. He would call upon the secretary to give a short summary of that correspondence.

The SECRETARY then read a few of the letters he had received with reference to the employment of young persons in electrical works, and in the majority of cases the writers were in favour of a representation to the Home Secretary in the matter. The secretary stated that there were in all 75 letters sent out by the Institution to central-station engineers asking them to send delegates to this conference, and 60 replies had been received. Of these, 12 stated that their works were unaffected by the Act; 14 that they had given up the employment of young persons in central stations in consequence of the Act; 25 replied to the effect that, in their opinion, the Act was prejudicial to the industry; six stated that they did not consider the clauses in question unreasonable; and three were of opinion that young persons under 18 years of age ought not to be put

Digitized by Google

in responsible positions. The secretary next gave a *résumé* of the contents of a number of letters from corporation electrical engineers sympathising with the movement, including the Corporations of Bath, Chester, Greenock, Leeds, Doncaster, Sunderland, Ayr, Coventry, Glasgow, Hastings, Huddersfield, Poplar, and Worcester.

The CHAIRMAN, in calling upon Major-General Webber to open the discussion, said that so far no regulations had been promulgated with respect to electricity stations under the Act of 1901, and up to the present whatever action had been taken had been by the local inspectors under the general terms of the new Act or under the terms of the Act formerly in force.

Major-General WEBBER, representing the London Chamber of Commerce, said there was no doubt that this was a matter of great importance, and one which would daily come more home to those connected with electricity supply; and when one came to think of the large areas which would be covered by the power stations, and the number of transforming points that would have to be established in connection with the generating plants, there could be no doubt that the incidence of this Act might be very oppressive to them, and also to the traction companies in certain circumstances. The wording of the clause which brought transforming stations within the Act was a little bit ambiguous—he should like to say insiduous—but it was certain that every place where electricity was to be transformed to be used by way of trade, no matter how insignificant it might be, came under the Act; and there was a great liability of electrical undertakings being interfered with in such a way as to seriously affect the industry and the standardisation of material. It would also possibly involve the scrapping of what they believed to be perfectly sound machinery when used by those who properly understood it. The object the Chamber of Commerce had in being represented at this conference was to strengthen the hands of the Institution in approaching the Home Secretary. He believed that there was every encouragement in that direction. They knew that the Government had recently appointed an inspector under the 1901 Act, and, also, that the Home Secretary was taking further action in the matter. It was time, therefore, for them to take action also.

Mr. PERCY STILL, representing the Chelsea Electricity Supply Company, said that his company was affected by the clauses regulating the employment of young persons. His experience was that by employing youths in central stations and sub-stations they had been able to educate them up in the particular work they were required to do. The work in sub-stations was, of course, very light, and it was a superior class of work for boys, chiefly consisting of watching. But this Act precluded them from taking their meals on the premises, and they could only be employed for a certain number of hours, and not on Sundays or holidays. In his opinion the application of the clauses referred to would render the employment of young persons on this work quite impossible. He begged to move the following resolution, which was the first on the list to be considered: "That in the opinion of this conference there are clauses in the Factory and Workshops Act of 1901 that are prejudicial to the industry of electricity supply."

Sir HENRY C. MANCE seconded the motion. His experience at Oxford was very similar to Mr. Still's case. In consequence of this Act he was recently forced to employ a number of men for sub-station work at high wages, whereas boys of 14 years of age could easily have done the duty.

Mr. ALBERT GAY, representing the Islington Borough Council, called the attention of the meeting to several clauses which more particularly applied to the industry generally as distinct from generating stations. He supported the resolution, and hoped that representations would be made to the Government which would enable some modification of the clauses which might be positively dangerous to the industry.

Mr. HARMAN LEWIS referred to the provision that the walls of central stations must be whitewashed every 14 months.

The SECRETARY reminded the speaker that Mr. Ferron, one of H.M. factory inspectors, had stated at a recent meeting of the Institution that electricity stations were to be exempted from that provision.

Mr. C. IRWIN, chairman of the Electricity Committee of the Dublin Corporation, stated that within the past few weeks the general inspector of the district had visited their power-house and ordered all the inside walls to be whitewashed. With regard to the provision relating to the employment of young persons, they were not affected by it in Dublin because they did not employ them.

The PRESIDENT then put the resolution to the meeting, which was carried unanimously.

Mr. J. S. RAWORTH next moved the following resolution: "That the Institution of Electrical Engineers be requested to take steps to approach the Home Secretary in order to lay before him the views expressed at this conference as to the prejudicial effects of the incidence of certain provisions of the Factory and Workshops Act of 1901 on the industry of electricity supply, and to pray him to allow the Institution to confer with him when he is framing regulations under the Act." He could not approach this subject, he said, without feeling that they were very much prejudiced by the name of the Act upon which they were called upon to work. Somebody had assumed that an electricity supply station was a factory. In his opinion it was very much more like a cathedral, and he undertook to say that if the Home Secretary had been taken into some of their beautiful electric light stations, he would never have consented to their being called factories at all. As for taking meals in them, he (Mr. Raworth) would just as soon take them there as in any restaurant. With regard to the employment of young persons, there were certain circumstances which made it desirable, for instance, that they should work late into the night in their own interests, for unless a boy could take his place in the shift he could not become a skilled man. Again, often a boy did certain work better than a man; and he was sure that if they did not bring their views on this matter very forcibly before the Home Secretary, they would be failing to carry out that responsibility they held for their working people. As regards the employment of boys on Sundays, he expressed no opinion, as he was not quite clear upon the point.

Mr. R. HAMMOND seconded the resolution, expressing the opinion that the Institution should have moved in this matter 12 months ago. The Factory Act in its application to electricity stations was based upon a misconception by the Home Office of the present-day state of central stations. It would be remembered that it was absolutely laid down in the draft regulations discussed by the Institution a short time ago, that the switchboard should be so built that no one could possibly touch the positive or negative terminal. That meant to this country an enormous amount of money being spent in redesigning switchboards, which would be absolute waste. This idea of covering up dangerous places was a great mistake, and often led to accidents. In those regulations, too, it was provided that no one should be allowed to work behind the switchboard unless he were a skilled electrician. These and other like provisions made it clear that they had been framed by people absolutely ignorant of what an electrical station really was.

Mr. W. A. CHAMEN said it must not be taken that he was representing the Glasgow Corporation there that afternoon, as they had decided that the notice given them was not sufficient to enable them to send a delegate. His own opinion on the matter, however, was that the Home Office was going out of its province in dealing with electrical stations, which should be left entirely to the Board of Trade. He heartily supported the resolution, but thought that they had hardly had time as yet to find out the most troublesome clauses in the Act.

The PRESIDENT felt that what was to be done by the Institution in this matter should be done at once. He further stated that the views of this conference would come before the committee of the Institution which had been appointed especially to deal with the subject, and would be considered by them before any action was taken.

Mr. CHAMEN: Then I support the resolution as it stands.

Digitized by Google

Mr. J. GRAY, representing the Crystal Palace District Electrical Company, remarked that their station had recently been remodelled, and the whole of the plant was in accordance with latest practice. About the end of last March an inspector of factories under the Act made a series of recommendations to the company, some of which had been carried out, but there were many others, which had not yet been complied with, and which would involve the company in very heavy expense, including the redesigning of the switchboard, which was now of the latest description. He felt that if these recommendations were to be met they would equally apply to every other central station in the country.

Mr. C. P. SPARKS mentioned the case of Bournemouth, where a similar case existed to that which the previous speaker had cited.

Mr. J. S. RAWORTH pointed out how very futile all these attempts to guard electrical machinery were. In the whole course of his experience he had only had one person injured, and in this case all the high-tension metal was carried overhead a distance of 8ft. above the floor. If a man wanted to kill himself, no one could prevent him.

Major-General WEBBER wanted to make it clear that this conference was by no means final as to what the Institution would recommend. The Council would refer the whole question to a very strong committee which they had appointed, and, if possible, this committee would be made more representative than it was at present. It would be the duty of the committee to move the Council to approach the Home Secretary. The great object they had in view was to fend off the possibility of regulations being passed which would not be in agreement with best knowledge and best practice. He thought that if the Institution approached the Home Secretary in a conciliatory manner, they would convince him that representatives of the industry were the best men to frame the rules. The result would be that all those who had shown interest in the subject that day would have an opportunity of saying another word before the regulations which he believed were coming would be made hard-and-fast.

On the PRESIDENT putting the resolution to the meeting it was carried unanimously.

Mr. SPARKS moved a very hearty vote of thanks to the chairman, which was carried, and the meeting separated.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

481. In a central station in which both batteries are temporarily disconnected, a 350-kw. machine and two 70-kw. steam balancers are on load (lighting and power) connected on + and − respectively of a three-wire system, the 350-kw. being across the outers, with its field excited from the negative bus bars. A slight load comes on to the − side, causing the volts on that side (−) to drop slightly; as the big machine and balancers are fully loaded up, another machine is ordered to be got ready. Before this can be done the volts on both sides suddenly drop to zero, and a total shut down is the result. How can this be explained, and could the shut down have been avoided? I might mention that the two 70-kw. steam balancers were self-exciting two-pole machines.—R. M.

482. Describe exactly how you would calculate the load factor of a lighting and traction station respectively, and in what way would the conditions for a maximum load factor differ in each case?—P.

ANSWERS.

Question No. 475.—Two alternating-current transformers are to be connected in parallel on a low-tension network; it is found that one of the transformers is apparently short-circuited when connected up, but upon changing either the high-tension or low-tension leads they are found to be correct. Why is this, and how could the proper connections be ascertained before connecting up?

Best Answer to No. 475 (*awarded* 10s.).—Fig. 1 gives a diagram of the connections of the two transformers, T_1 and T_2, which it is desired to put in parallel on the secondary mains. S S = secondary switches, P S = primary switches, and F = fuse (on high-tension inner). The terminals of transformer coils are often marked "inner" and "outer," and sometimes even "+" and "−," so it would seem that the only thing to do to put the transformers in parallel would be to see that the ends of coils of like sign were put on the same secondary mains—viz., inner to inner and outer to outer—and then the two transformers would work all right together. This doesn't

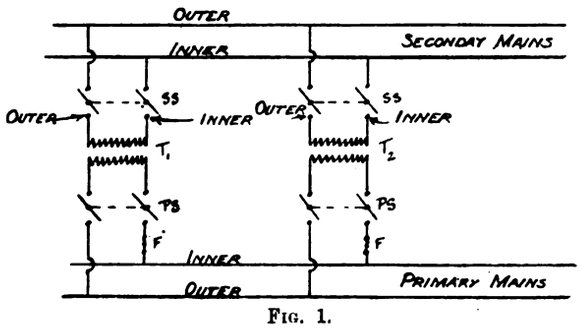

FIG. 1.

always come right, however, as, even with two transformers by the same maker, having to all appearances similarly-wound coils which when put in parallel and all transformer switches closed, blows the transformer fuse or fuses, the result of an apparent short-circuit as stated by "T. H." The secondary ends of one coil, although marked "inner" and "outer," may be marked wrong, or this coil may be wound in opposite direction to the other one, the result being that one coil is short-circuited through the other, thus blowing the fuse. Referring to Fig. 1, let T_1 have its switches all closed and be working on mains. It is desired to put T_2 in parallel with it. If its secondary terminals are connected up, as shown, then the two transformers will work in parallel all right. But should "inner" of T_2 be connected to "outer" secondary main, and "outer" to "inner," due to aforesaid reasons, then T_2 will be short-circuited by T_1, the result being that fuse blows. To make sure that this will not occur before closing the switches, the best thing to do is (with

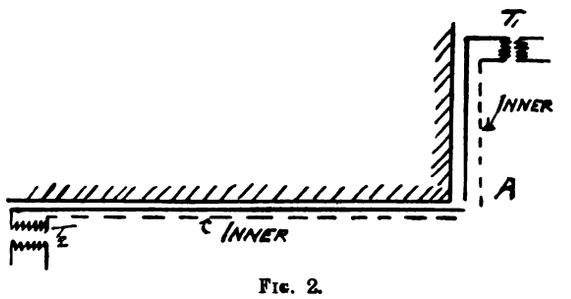

FIG. 2.

all switches open) connect the two secondary "outers" together by means of a piece of light fuse wire, also connect the two "inners" in same way. Then close primary switches, and if nothing happens, then they are properly in parallel. If fuses blow, cross-connect one secondary transformer, and they will be found to be right. Another way would be to connect an "inner" and an "outer" together, then close primary switches, and try two lamps of the secondary voltage in series across the remaining ends of coils If they light up, the transformers are in series, and one secondary requires cross-connecting to put them in parallel. This is all right where the two transformers are alongside each other, but when they are in different streets a considerable distance apart, as shown in Fig. 2, then proceed as follows: T_1 and T_2

Digitized by Google

are the transformers. It is desired to put in parallel by jointing up the secondaries at point A. I am supposing that T_1 and T_2 are sunk in pavement and have heavy covers, which it is a trouble to lift, and we wish to avoid blowing either transformer fuse. With both transformers alive, connect the two outers at point A together by means of a piece of fine fuse wire. Connect a piece of fuse wire to one inner at A, and with a gloved hand or by means of a piece of wood touch this fuse wire on to the other inner, and if nothing happens, then the transformers will be right for putting in parallel, and joint may be made at A. Should the fuse wires blow, however, then one transformer cover will require to be lifted and its secondary mains cross-connected, when all will be found right. The cables, of course, will be concentric, but I have shown single lines for clearness.—R. S.

Answer to No. 475 (*awarded* 5*s.*).—A diagram (Fig. 1) will best explain the first question. This causes a dead

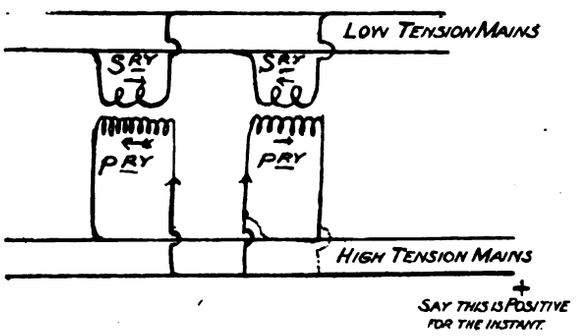

FIG. 1.

short-circuit in both transformers, but if primary winding of right-hand transformer is connected as per the dotted lines, then, if the transformers have both the same ratio, no

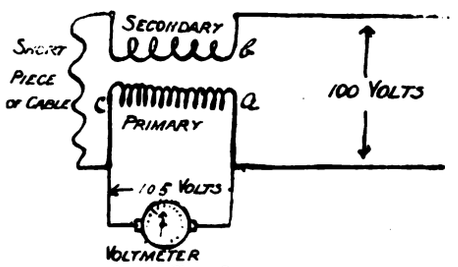

FIG. 2

current will flow between them. Of course, if when connected up with like terminals together and a short is found to occur, then whether you change the primary or secondary

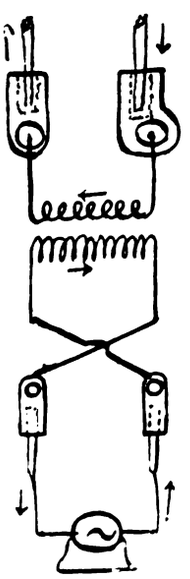

FIG. 3.

leads over on one transformer it will not matter, provided you change over only the high or low tension leads, because what is wanted is for both transformers to feed low-tension mains. The best way that I know, and one I have used for some hundreds of times, is as follows (and is as far as I know original): Two transformers can be used to test each other. If the transformer that we wish to test has a ratio of $\frac{2,000}{100}$ volts, we connect one end of primary to one end of secondary, and then put any convenient alternating voltage across the remaining ends, as Fig. 2. First measure volts across *a b*, which is, say, 100 volts; then, still keeping 100 volts at *a b*, measure across *a c*. This will be less than *a b* (say, 95 volts) if transformer is connected up rightly, and more than 100 volts (say, 105) if connections are wrong. The general standard method of connection is shown in Fig. 3 (as the direction of voltage in the secondary is opposite to that of the primary), and so by this arrangement we have adjacent terminals of like (instantaneous) polarity. It does not matter how they are connected, provided they are all the same, but it is best to stick to one rule, because at some future time another transformer may have to be added. By the method I have described you can test with certainty, without danger and with a very small current, a number of transformers (of any ordinary voltage and ratio) in a very short time. A Cardew voltmeter is quite accurate enough.—A. R. C.

Answer to No. 475 (*awarded* 5*s.*).—The effect mentioned is exactly analogous to what occurs when two continuous-current dynamos are connected in parallel. If brushes of dissimilar sign are connected to the same 'bus bar, the fuses will at once blow due to an enormous current passing through the two armatures in series. In Fig. 1 are shown two transformers incorrectly connected together. The instantaneous directions of the voltages in the voltages in the different windings are shown by the arrows. It will be seen that a complete short-circuit is formed by the two secondary windings in series, and that round this short-circuit the combined voltages of the two secondaries act in unison. This naturally leads to an excessive current in

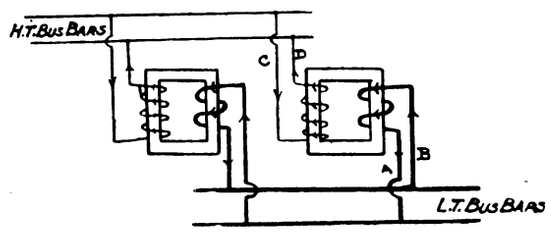

FIG. 1.

the secondaries, which reacts on the primary current and makes that also excessive, so that the fuses blow whether placed in the secondary or the primary circuit. When the leads A and B (Fig. 1) are crossed over (or, which comes to the same thing, the primary leads C and D are crossed over), it will be seen by the arrows that the secondary voltages are in opposition as far as passing current round the two secondary windings in series is concerned, though they are in unison as far as the 'bus bars are concerned, and consequently will now work satisfactorily in parallel.

There are three fairly simple methods of determining beforehand which terminals of transformers intended for parallel running may be connected together: (1) If the transformers are conveniently situated and are not in cases, the direction of winding can usually be followed out, and it is then easy to ascertain by inspection the relative directions of current in the two secondaries with given primary terminals connected to the same 'bus bar. (2) If the transformers cannot be conveniently inspected, the following method can be employed. It requires the use of a galvanometer of any ordinary sort, merely for indicating direction of current, and a small source of continuous current, such as a primary or secondary battery. Connect the secondary of one of the transformers to the galvanometer (shunted if necessary), and switch a small continuous current into the primary, and note the direction of the galvanometer deflection. Repeat with the second transformer, and change the connections until the galvanometer is deflected in the same direction as before. Then those secondary terminals belong together which were connected

Digitized by Google

to the same galvanometer terminal, provided that the primary terminals which were connected to the same pole of the battery are connected to the same 'bus bar. (3) The simplest, quickest, and most usual method, however, consists in simply connecting pieces of fuse wire to the secondary terminals of the unknown transformer, and, after connecting the primary to the mains, tapping the secondary on to the live low-tension 'bus bars. If incorrectly coupled, there will be a flash, and the fuse wire will immediately be melted, whilst if correct, a comparatively small current only will pass from the secondary into the circuit.—Q.

Answer to No. 475 (*awarded* 5*s.*).—The reason for No. 2 transformer appearing to be short-circuited, when coupled in parallel on the network with No. 1 transformer, is due to the fact that its primary winding has not been so coupled up to the high-tension

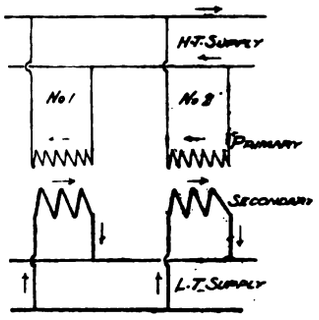

Fig. 1.

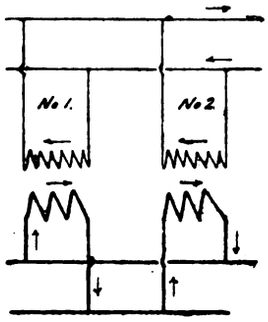

Fig. 2.

supply mains as to cause the induced E.M.F. in its secondary winding to be in the same direction at the same instant as the induced E.M.F. in the secondary winding of No. 1 transformer. The result is that the E.M.F.'s induced in the secondary windings of these two transformers, instead of acting in parallel on the 'bus bars or network (Fig. 1), are acting in series round the closed circuit formed by their secondary windings (Fig. 2), and as this E.M.F. will be approximately double the low-tension supply pressure acting round this closed circuit of low resistance, an excessive current will flow and cause the fuses to melt. Transformers are usually so wound and coupled up to their terminals by the makers that if similar high-tension and similar low-tension terminals are coupled up to the same high-tension and low-tension 'bus bars, the transformers should work properly in parallel, but a polarity just such as explained below should always be made to ascertain that such is the case before putting the transformers in parallel.

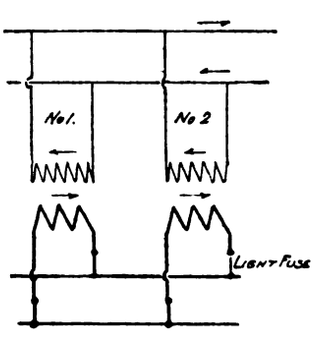

Fig. 3.

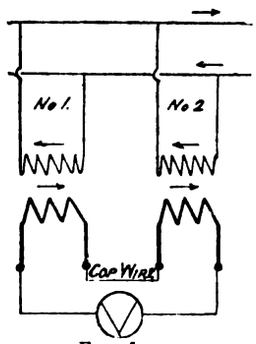

Fig. 4.

Method 1.—If the transformers are not on load, a test may be made by coupling the primary windings of both transformers to the high-tension supply, then coupling up both poles of No. 1 transformer, and one pole of No. 2 transformer by strong fuses, and inserting a small fuse in the remaining pole of No. 2 transformer (Fig. 3), and if they are coupled up properly for parallel working no current should flow between them, and the fuse will remain intact—*i.e.*, assuming that they are properly wound for working in parallel. The small fuse may now be removed and replaced by usual size, and the transformers will be ready to take up the load.

Method 2.—If No. 1 transformer is on load and No. 2 is required to be coupled in parallel, a test may be made by coupling up the primary windings to the high-tension supply, then coupling two of the secondary terminals together by a copper wire, and taking a voltmeter reading across the remaining two secondary terminals (Fig. 4). If the voltmeter does not indicate any difference of potential, the terminals coupled together by the copper wire should be coupled to one 'bus bar, and the two terminals connected to the voltmeter should be connected to the other 'bus bar; but if the voltmeter reading is double, the low-tension supply pressure the terminal of No. 1 connected to the voltmeter should be coupled to the same bar as the terminal on No. 2 connected to the copper wire, and the terminal on No. 1 connected to the copper wire should be coupled to the same bar as the terminal on No. 2 connected to the voltmeter. The transformers may now be plugged up and put to work. If a voltmeter is not to hand, a couple of lamps of the same voltage as the supply, and each of the same candle-power, may be connected in series and used to indicate roughly double the low-tension pressure.

Referring to Fig. 2, it will be seen that if either the high-tension or low-tension leads of either transformer are changed over, the transformers will be connected in proper order for parallel working.—H. F. J. T.

Question No. 476.—In a low-tension three-wire system, after a time the insulation on the negative side displays a persistent tendency to break down. This gradual deterioration is said to be due to osmosis; define the term when applied to the foregoing effects, and explain why the negative should exhibit such a tendency.

Answer to No. 476 (*awarded* 7*s.* 6*d.*).—The term "osmosis" is used to denote the phenomenon which is exhibited by liquids or gases of different specific gravities or viscosities when separated by some membranous substance, the effect being the transference of the lighter substance to the heavier. This phenomenon is very common in nature—*e.g.*, the fluids in plants being thus transferred from the outer to the inner cells, where the contents are more solid, thereby increasing the size of the structure. This can be demonstrated quite easily by taking a small jar full of syrup (treacle), tying a piece of parchment tightly over the mouth and immersing the whole in a vessel of water. In the course of time it will be noticed that the parchment is distended owing to the transition of water to the heavier liquid in the jar. This action would continue until the two liquids assumed the same specific gravity, except that the parchment would burst long before that took place. This action is also noticeable in primary cells having porous pots.

In the case under consideration this phenomenon seems to be accentuated by the electrical action. In a three-wire system the negative wire is at a potential below the earth potential equal to half the pressure across the outers of the system. Thus any leakage which takes place will be *from* earth into the conductor. The moisture in the ground surrounding the cables is impelled, by this "charging" of the negative wire from the earth, through the insulation more quickly than would otherwise be the case. When the cables have been in the ground for some time, a very small amount of moisture may have entered the microscopic pores of the rubber, paper, diatrine, or whatever insulation is used, this being in the direction of flow of the leakage or "charging" current, and a slight electrolytic action would be set up with the copper of the conductor. The conditions for "osmosis" would then be ripe. The copper compounds being of greater density than the water outside the rubber or other insulation, the latter would endeavour to dilute the former. Of course, as there is no exit for the water now inside the insulation, it creeps along the conductor at first until the quantity is so great as to stretch the rubber, etc., forming blisters, or balloons, until at last it bursts, when practically a dead earth is formed.

In a triple-concentric cable, with the "middle" wire as the outer conductor of the three, there is very little liability to this action, especially if the middle wire be not earthed. Even if the cable be lead sheathed there is a liability for this action to set up, for if by any means an appreciable current gets on to the lead, and so to earth, from the middle wire, electrolytic action will corrode the lead at the place where the current leaves for the earth and neighbouring conductors, thus making a way in for the water. If the middle wire be earthed, of course, the negative is subject to the same stress due to the earth potential, as in the case of separate conductors.—Mundy.

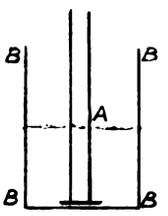
Answer to No. 476 (*awarded* 7*s.* 6*d.*).—This phenomenon has nothing whatever to do with osmotic action, which can only occur when certain liquids or gases are in the presence of a more or less porous diaphragm. The best way to observe osmosis is to get a glass tube, A (see sketch), and close one end of it with a piece of unglazed earthenware, which should be fairly thin, and may be stuck on by sealing-wax. A piece of bladder would do as well as the plate of unglazed earthenware, but it must be tied very tightly on to the tube by cotton. This tube



should then have a strong solution of table salt or sugar put into it, enough to about half fill it. Half a minute's careful observation will show that it does not leak at the joint. This being ascertained, the tube should be stood in a glass, and plain water put into the outer glass, B, as high as the level of the solution in the tube. Diffusion or osmosis will now take place, and the liquid in the tube will rise against the action of gravity, because these two liquids will diffuse through the diaphragm with rapidities inversely proportional to the square roots of their densities, and therefore the water being the least dense, will pass through more quickly than the solution of salt or sugar. A may be a gauge glass and B an ordinary tumbler, while a broken battery jar will furnish the diaphragm. Electric osmosis has also been observed, for if a + wire be put into the glass, B, and a - wire from the same battery into the tube, A, while the liquid in each has the same density, the liquid being part of the circuit will move in the same direction as the electric current, and will, therefore, mount up in the tube.

The cause of the breakdown in the insulation of the negative supply wire is altogether different from the above. In the first place, the wires are probably laid in a damp, underground passage, which is never dry. Moisture, which, of course, is really water, exudes from the earth and either creeps along the supports to the insulators and wires or else it is condensed by them, and so in a short time makes a continuous film, connecting everything inside the culvert. This film is well able to dissolve any alkaline or other salts which may be in the earth and so spread them all over everything on which it rests. The insulation of the wires is not quite impervious to moisture, and, therefore, not to the salts—*i.e.*, which it holds in solution. Water containing alkaline salts is a good conductor of electricity, and so a leak developes on the circuit, and electricity passes through this film of moisture from the positive to the negative wire, performing an electrolytic action as it goes. The first consequence of this electrolytic action is to set free caustic alkalies on the negative wire, and the chemical action of these caustic alkalies is very destructive to the insulation. The result of the electrolytic action on the positive wire is to set free on it gases and acids. These are mostly united by the same action with the copper and are then rendered harmless as a general rule, but in so doing they have, of course, made a certain proportion of the wire unable to conduct electricity, and have, moreover, materially injured it. These copper salts would, when dry, be non-conductors of electricity, and it must be borne in mind that many salts of copper, and notably the sulphate, have the property of solidifying water when crystallising, so that the crystals are sensibly dry and are non-conductors of electricity because they have crystallised with themselves the small quantity of water in contact with them. In this state the insulation of the positive wire might be good for a short time, but, of course, damage is being done, and the acids as they are set free damage the insulation of the positive wire. The total resistance of the positive wire is increasing under this action, which, if allowed to go on, and more especially if it is at all energetic in one spot, will eat away a part of the wire completely. This nuisance I have known happen several times, and it is apt to be very dangerous, because the wire becomes so thin that it might develope heat unduly and set fire to the insulation before it breaks continuity completely. "Student" would do well to get the *Electrical Engineer* for Feb. 14 last and read the answers to question No. 449, which go very fully into this matter, and, in fact, with what I have said above give practically all the information there is on this important subject.—F. G. A.

Answer to No. 476 (*awarded* 5*s.*).—Damp is a great source of danger to cables and tends to lower the insulation, and sometimes causes a tendency to breakdown. When water gains access to the cable it is apt to set up electrolysis, which may even affect lead-covered cables laid directly in the ground or drawn into ducts, as flooding of the ducts with water may occur, or it may get sometimes inside the joint-boxes and attack the cable joints, or some weak spot exists through which water enters. Water even may condense more or less inside, according to the state of the weather, and cause the cable to be alternately wet and dry, and this condition has a disintegrating effect upon the insulation, so that a cable after a time being in use and exposed to these causes may have the insulation resistance lowered. On testing, for instance, it might be found that the insulation resistance of the + conductor was, perhaps, over 160 megohms, and the (-) conductor not more than 30 megohms, with, say, 100 volts between them. Such a condition as this is due to electrolytic action, and it is this which causes such a marked difference in the insulation of the + and (-) conductors. The immediate cause of this is *electrolytic osmosis*, which we define as a phenomenon in which moisture is attracted to a negatively electrified conductor and repelled from a positively electrified conductor, and the reason of the (-) conductor being thus affected and not the + conductor is the attraction the former has for moisture, and the following experiment shows what is meant: If two conductors are taken and joined by means of saturated threads with a vessel of water and the potential of one of them be maintained above that of the water (the natural chemical affinity holding the elements H and O together in water equals an E.M.F. of 1·5 volts), and the other below it, moisture will travel along the threads to the negative conductor and away from the + conductor. The result of this action on a cable is that the insulators supporting the (-) conductors, or if continuously insulated the ends of the cables become damp, the insulation resistance falls, and in time it may lead to a breakdown. Especially is this the case if the water, instead of being pure, is impregnated with mineral salts from the soil and chemical substances from the surface of the roadways. Should there be any Portland cement in solution, this will certainly affect rubber-covered cables. Callender's solid system of laying cables in troughs, surrounded with Trinidad bitumen, excludes all moisture, and so tends to preserve the insulation.—J. A.

Answer to No. 476 (*awarded* 5*s.*).—Electric osmose is the name given to the phenomenon observed when a current passes between two electrodes in a liquid, the electrodes being separated by a porous diaphragm. The liquid in the division containing the positive pole is found to decrease, while a corresponding increase is noted in the division in which is the negative. When the liquids in which the electrodes are immersed are non-conducting, the action is greater than when they are conducting; for instance, the action in the case of water (H_2O) is greater than with dilute sulphuric acid (H_2SO_4), while alcohol (C_2H_6O) gives even an increase over water. Thus the phenomenon appears to vary inversely as the conducting power of the liquid. In the case of electric light mains we have the electrodes represented by the copper conductors, and the porous division by the earth or intervening media. It would, therefore, appear quite to be expected that an accumulation of moisture would gather round the negative lead. This would tend to lower the insulation of the negative side, and facilitate "earthing." It must also be taken into consideration that in proportion to the leakage between the mains we have hydrogen given off at the negative, and that this hydrogen is nascent, thus

Digitized by Google

being in a very active condition. I may say that in the plant under my charge the several "earths" that have given us some trouble have been on the negative main; these faults were attributed to some such action as suggested in the question.—M. M.

REDDITCH ELECTRICITY ACCOUNTS.

The total expenditure on capital account to Dec. 31, 1901, under the Redditch electric lighting order amounted to £20,568. We append abstracts of the revenue account and give balance-sheet:

REVENUE ACCOUNT.

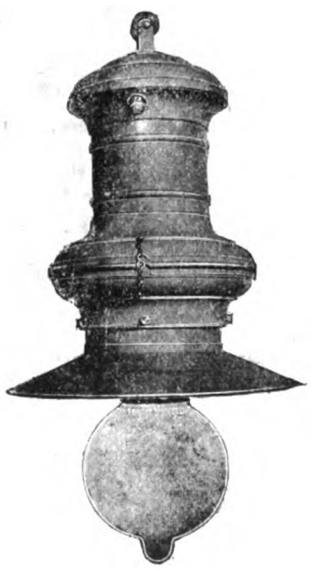
TRADE NOTICES AND NOVELTIES.

Flame "Ark" Lamp.

Messrs. Johnson and Phillips, Victoria Works, Old Charlton, Kent, inform us that they are putting on the market a lamp which will be known to the trade as the Flame "Ark" lamp. The principal feature in regard to this lamp is the long life of the carbons with one trimming. In fact, we understand the average life of the special flame carbons supplied with the lamp is about the same as that of ordinary carbons used in enclosed arcs. The light emitted is of a rich golden colour, possessing, it is stated, high fog-penetrating powers. In some of the lamps which have been tested the amount of light obtained has averaged as much as four candles per watt consumed. As regards construction the lamp combines the same simplicity of mechanism as that obtaining in the firm's ordinary type of "Ark" lamp. To sum up, the advantages claimed for the Flame "Ark" lamp are as follows: moderate first cost, low current consumption, and economy in carbon consumption and attendance. Messrs. Johnson and Phillips have already made a speciality of "Ark" lamps with coloured globes for Coronation illuminations, and their Flame "Ark" is now added as a supplementary means of illumination, being suitable either for interior or outside lighting. Another point in its favour, and a most important one in view of the large demand which will have to be met in connection with the approaching festivities, is that the lamp can be supplied from stock.



The accompanying illustration shows the general appearance of the lamp.

B.T.H. Motors.

From the British Thomson-Houston Company, Limited, Rugby, we have received two descriptive pamphlets. The first—No. 122, which supersedes No. 80, Nov. 21, 1900—deals with slow and moderate speed motors of the B.T.H. "M.P." type. These machines have, we are told, recently been redesigned, and in their new form embody all important improvements known to present electrical engineering practice. They are of four-pole construction, the armature coils being machine made, separately insulated and interchangeable throughout each size and voltage of motor. Moreover, the armature coils are embedded in slots in the face of the core, and are thus protected from mechanical strain or abrasion by the pole-faces. The protecting flanges of the spider support the armature windings, and, besides affording additional radiating surface, protect the windings from oil or mechanical injury. Many other advantageous features

Digitized by Google

of construction are enumerated, but for these we must refer the reader to the pamphlet under notice. The slow-speed (800 revolutions down to 470 revolutions per minute) motors listed range in output from 15 h.p. to 85 h.p., and the moderate-speed (1,100 revolutions down to 655 revolutions per minute) machines from 20 h.p. to 95 h.p.

The second pamphlet—No. 123—which supersedes Nos. 95 and 100, issued last year, deals with B.T.H. direct and alternating current fan motors. These motors are claimed to combine economy with durability, the first being secured by a perfect electrical design, and the second by a thorough consideration of the mechanics of the motor. The direct-current fan motors are made for operating on 60, 80, 95 to 115, and 190 to 230 volt circuits. All have regulating switches with four points, providing for three different speeds. Numerous methods of fixing the motors are illustrated and described. For attaching to light partitions which vibrate easily and tend to act as sounding boards, the bracket fan motor is recommended. This consists of an ornamental motor suspended from a brass bracket by means of coiled springs designed to absorb vibrations.

Toothed Gearing.

From the "Buffoline" Noiseless Gear Company, Chapel-street, Levenshulme, Manchester, we have received a copy of their new catalogue of toothed gearing. The firm, we learn, usually make their patent "Buffoline" pinions to gear with machine-cut wheels. These pinions are used for electric motors, pumps, cranes, printing machines, textile machines, motorcars, etc. It is claimed, among other advantages, that they are noiseless, very light in weight, twice as strong as cast iron, and produce no vibration. Various styles of the pinions are illustrated, also a "Buffoline" mallet fitted with a steel shaft. Machine-cut cast-iron or steel spur wheels up to 11ft. diameter are also supplied by the firm.

Tramway Apparatus.

We have received from the International Electrical Engineering Company, of Clun House, Surrey-street, Strand, a copy of their recently-issued bulletin (No. 6) describing electric tramway apparatus. We note that the company laid down the first electric tramway in Belgium so long ago as 1892, and besides carrying out much work on their own account, the Liège works have for many years supplied traction motors and controllers in quantities to other manufacturers. The bulletin contains a description of the firm's latest type of motors, controllers, lightning arresters, etc., and is well illustrated. Particulars are given of the tractive effort, weights, etc., of standard motors, ranging from 7½ b.h.p. to 35 b.h.p. The prices of these motors, and also of controllers, resistances, lightning arresters, automatic cut-out switches, safety fuses, and canopy switches, are quoted.

Motors and Arc Lamps.

We have received from the Westminster Engineering Company, Limited, Victoria-road, Willesden Junction, N.W., a copy of their new illustrated list of motors. The machines listed include motors of the "Westminster" four-pole semi-enclosed continuous-current type, ranging in output from ½ b.h.p. to 40 b.h.p., and enclosed motors of from ¼ b.h.p. to 36 b.h.p. output. The weights and over-all dimensions of the machines are given, in addition to the prices. From the same firm we have lists illustrating two arc lamps of the enclosed type, one of these lamps being designed to burn 90 hours and the other 70 hours with four to eight amperes, singly on 100 to 110 volts, or two in series on 200 to 220 volts, etc.

Glass Shades.

Several new and attractive patterns in glass shades are illustrated in circular No. G 1,004, just issued by the General Electric Company, Limited, Queen Victoria-street, London, E.C.

Date Nails.

From Mr. John Milliken, 2, Belfast Bank-chambers, Belfast, Ireland, we have received a card describing a galvanised date nail which he has just introduced for dating railway sleepers, telegraph and telephone poles, and for general use where wood is employed and renewals have to be made. In railway work the nail is driven into the centre of the sleeper to be placed in the line before it leaves the depôt. The head of the nail bears a figure indicating the year. The nails, we are told, run from about 5,160 to the hundredweight, so that 1cwt. would date on the average, say, 2½ miles of track.

LEGAL INTELLIGENCE.

CITY AND SOUTH LONDON RAILWAY.

Mr. Justice Wright, sitting in the King's Bench Division of the High Court on Wednesday, had before him the matter of an arbitration between the City and South London Railway Company and the rector and churchwardens of the united parishes of St. Mary Woolnoth and St. Mary Woolchurch Haw. It came before the Court on a special case stated by the arbitrator raising the question as to the basis on which the rector and churchwardens of the united parishes of St. Mary Woolnoth and St. Mary Woolchurch Haw were to be compensated for that part of the site of the church of St. Mary Woolnoth which the railway company had taken for the purpose of extending its line from London Bridge to the Angel at Islington. It appeared that the arbitrator arrived at three alternative findings. He awarded against the company £90,628 if all the lands taken belonged to the site of St. Mary Woolnoth and could never be used for any other purpose; or £136,421 if the lands taken might have become at some future time available for building purposes; or £143,548 if the site of the church and the other land could be made immediately available for the erection of buildings other than a church. The company contended that the compensation should be awarded on the basis that all the lands taken formed the site of the church, and could never be used for any other purpose.

His Lordship held that the claimants were entitled to compensation on the basis that the site of the church might at some future date become available as a building site.

HASTINGS TRAMWAYS.

In the Chancery Division Mr. Justice Buckley had before him the case of Bray *v.* the Hastings Corporation, which was an action brought for a declaration that an agreement purporting to be made between the Hastings Tramway Company, the defendants, and Mr. W. M. Murphy was illegal, and also claiming other relief.

Mr. Terrell, for the defendants, said that his clients had communicated with the solicitors who acted both for Mr. Murphy and the tramway company, and they said that they had no instructions from either party, but they added that they would apply for instructions. Under these circumstances it was impossible to proceed.

The case accordingly stood over till next sittings.

ACTION FOR PERSONAL INJURIES.

In the Westminster County Court on Monday, his Honour Judge Woodfall and a jury had before them the case of Marsh *v.* the Charing Cross and City Electric Company, Limited, in which the plaintiff, a wireman, sued the defendant company to recover damages for personal injuries sustained owing to the alleged negligence of the defendant company.

The **Plaintiff** was called, and said that on Oct. 9 last year he was sent to a manhole at Ludgate-hill, in company with another man named Ray, to carry out certain repairs, and whilst so engaged there was a fusing of the wires. An explosion followed, as a result of which he sustained very severe personal injuries, from which he had not yet recovered. His fingers and eyes were severely burned and part of one of his ears was destroyed.

After hearing other evidence **His Honour** said the accident was a most regrettable one, but there was absolutely no evidence of negligence on the part of the defendant company, and in those circumstances he had no alternative but to enter a non-suit. The jury were accordingly discharged.

COMPANIES' MEETINGS AND REPORTS.

BRISBANE ELECTRIC TRAMWAYS.

The annual general meeting of the shareholders in this Company was held on the 8th inst. at Winchester House, Old Broad-street, Mr. H. R. Beeton presiding.

The **Chairman**, in moving the adoption of the report, reminded them that this was the first annual general meeting of the Company, and the accounts comprised a period from its formation on Nov. 20, 1900, up to Dec. 31 last. They showed a net balance available of £42,815. 5s. 4d., out of which they had already paid the debenture stock interest and an interim dividend on the preference shares, and now proposed the payment of a balance dividend of 2s. 6d. on the preference shares, making up the full 5 per cent. per annum, leaving £7,523. 13s. 3d. to the credit of the next account. This Company was formed to acquire the shares of the Brisbane Tramways Company, Limited, all of which they held, with the exception of the 107 shares which were required to be held outside the Company for statutory reasons. The record of the Brisbane Tramways Company had been one of continuous progress since the date, in 1896, when the tramway system was first taken over for the purpose of conversion to electric traction. To-day there was, by universal admission, the first electric tramway installation in Australia, and their manager reported that the omnibus proprietors, who were still lingering on, were now contemplating the disposal of their business. The Company had undertaken to construct certain additional lines, and to extend the equipment of their power station. At the time the Company took over the tramways they had about 20 miles of street and about 33 miles of single lines. Since that time, to the end of last year, they had opened about five additional miles of street or nine miles of single lines, and there remained to be opened a further seven miles of street and about another eight miles or more of single line. From the summary of receipts and expenditure of the tramways company, presented in the report, it would be seen that during the past year they worked at a percentage of 58 per cent., and they had reason to anticipate that a more satisfactory result would be reached in the future. Mr. Badger, the manager of the lines, was not only a very accomplished and experienced engineer, but he was an accomplished and resourceful tramway manager. He was also a most able diplomatist in the conduct of their affairs.

Mr. A. McIlwraith seconded the resolution, which was unanimously agreed to.

CUBA SUBMARINE TELEGRAPH.

Mr. Chas. W. Parish presided over the ordinary general meeting of this Company at the offices, Old Broad-street, and, in moving the adoption of the report, said it did not require much explanation, for of late the Company's half-yearly statements had been very similar to each other, and they contained no special items

Digitized by Google

calling for particular attention, but in reviewing the last six months of 1901 with those of 1900 they had two periods of working under the same conditions, and he was pleased to be able to point out that July to December, 1901, yielded the Company a traffic of £9,270, against £8,903 for the same six months of 1900. The broken cable between Cape Cruz and Santiago, referred to in the last report, had been successfully repaired. The Board were still unable to announce the settlement of the Company's claim for damage done to the cables during the Spanish-American war. It was understood that the Bill in connection with the matter was now pending in the House of Representatives, and a communication on the subject had been received from the Foreign Office, who had helped the Company as much as possible. The Board believed that during this month the new Government of Cuba would take charge of the island and all its affairs, and they would then put forward the Company's claim for the overdue subsidy for the coast cables in accordance with the concession. The appeal of the West India and Panama Telegraph Company to the House of Lords had not yet come up for decision, but the directors were informed that it would probably do so in the autumn. He concluded by moving the adoption of the report, which was seconded by **Mr. R. Kaye Gray.**

A **Shareholder** enquired whether any information could be given as to what effect the Marconi system was likely to have on the Company's property?

The **Chairman** replied that, so far as the Board understood the Marconi system, it appeared to be in a very early stage yet, and was not likely to affect the shareholders' pockets in any degree. Scientific gentlemen on one side said that it was a good system, while others declared that it was of no use.

The resolution was carried unanimously, and the proposed dividends for the half-year were also sanctioned—namely, at the rate of 10 per cent. per annum, subject to income tax, on the preference shares, and 4 per cent. per annum, free of income tax, on the ordinary shares.

TELEGRAPH MANUFACTURING.

An extraordinary general meeting of this Company was held on Friday at Liverpool to consider the proposal to amalgamate the Company with the British Insulated Wire Company, Limited. Mr. James Taylor presided.

The **Solicitor** read the agreement, dated April 28, 1902, between the Telegraph Manufacturing Company (the vendor) and the British Insulated Wire Company (the purchaser). The vendor company agrees to sell and the purchaser company to purchase the whole of the assets and undertaking of the vendor, except the sum of £12,354, which the vendor company retains. The purchaser is to pay to the vendor company the sum of £400,000, to be satisfied by the allotment to the vendor company or its nominees of 20,000 fully paid-up preference shares of £5 each, and £30,000 fully paid-up ordinary shares of £5 each in the purchasing company. The sale takes effect as from Dec. 31 last, and is to be completed on May 31. The name of the purchaser company is to be changed into one embodying the distinctive features of the name of the two companies.

The **Chairman,** in moving that the agreement be confirmed, said it had been evident for some time to the directors that competition was increasing, and, therefore, the directors had come to the conclusion it would be better to enter into partnership with a large firm doing this class of work rather than continue competitors, especially in view of the fact that two large companies in the South in a similar business were joining hands. The last four months showed a very substantial increase in the business of the British Insulated Wire Company, and with the prospect of better foreign trade the shares ought now to stand higher in the market.

The resolution was carried unanimously.

WESTERN TELEGRAPH.

The ordinary general meeting of this Company was held at the River Plate House in the City on Wednesday, Sir J. Wolfe-Barry presiding.

The **Chairman,** in moving the adoption of the report, remarked that it was not altogether as satisfactory as the directors could have wished, because the message receipts had amounted to only £209,000, showing a decrease of £43,000 as compared with those for the December half of 1900. The receipts of the six months to December, 1900, however, were the largest that the Company had ever secured, owing, to a large extent, to the interruptions and inefficient working of competing lines. In the period under review they had also been working at a lower tariff than that which was in force in 1900, but the more important consideration affecting them was the fact that general business in South America had been, and continued to be, on a very much smaller scale than it was in the corresponding period of the previous year. There was, however, nothing whatever to discourage the shareholders in the accounts now submitted. The original cable laid along the coast of Brazil had for the last year or two kept their cable ship so constantly engaged in repairs that the directors decided to renew and in some parts divert the course of the cable at several positions where frequent interruptions occurred. The operations had just been carried out by a chartered cable steamer, the expense of which would be shown in the current half-year's accounts. The renewals had greatly improved the condition of these sections, and duplex working had been successfully applied to one of the cables, a measure which was impracticable before. The result of the half-year's working was that the usual first and second interim dividends had been paid, £40,000 had been carried to the general reserve fund, and £2,000 to the maintenance ship's reserve fund, leaving £5,531 to be carried forward. The shareholders would also remember that a dividend of 7 per cent. was paid for 1901, being the same rate as had been paid for many years, and that the directors were able to place £79,000 to the reserves. The condition of the Company, therefore afforded no reason for anxiety. With regard to wireless telegraphy, he saw no reason whatever to alter the opinion he had formed, that, although wireless telegraphy might be a useful handmaid to cable companies, he did not regard it as a serious competitor.

Mr. D H. Goodsall seconded the motion, which was carried unanimously.

WEST INDIA AND PANAMA TELEGRAPH.

Presiding over the ordinary general meeting of the shareholders in this Company on Wednesday, **Mr. W. S. Kingsford** said that the Company had suffered severely in consequence of the Martinique disaster. They had lost their vessel, the "Grappler," with all on board; also the staff on the island, and four of the cables of the Company had been broken, with the result that there was no communication south of St. Lucia. He suggested the passing of a vote of condolence with the relatives of those who had lost their lives in this unprecedented disaster. In the result a resolution was carried authorising the Board to do all that was needful out of the funds of the Company to alleviate the distress of those relatives of their servants who had perished. Dealing with the affairs of the Company, the chairman pointed out that they had chartered a swift steamer for the conveyance of telegrams between the points of interruption, and the delay occasioned was not serious—from 24 to 48 hours. Happily, there had been no loss of life so far as the Company's employés in St. Vincent were concerned. It was too early yet to estimate what the cost of the disaster to the Company would be, or to say whether it would become necessary to trench on the reserve fund to any extent. Referring to the report and accounts, the chairman observed that as compared with the corresponding period of 1900 there had been an increase in revenue of £944 and a decrease in expenditure of £1,125.

The report was adopted.

PRIMITIVA GAS AND ELECTRIC LIGHTING.

The annual meeting of the shareholders in this Company was held at the offices, Bank-buildings, Lothbury, this week, Mr. H. E. Jones presiding.

In moving the adoption of the report, which appeared in our last issue, the **Chairman** observed that it was necessary to call attention to the reconstruction of the capital account, the present being the first meeting of the new company in England. The leading gas companies supplying the metropolis had converted their 10 per cent. stock into £250 of 4 per cent. stock, and this measure corresponded very much with what had been done in the case of their Company. The directors had had to deal with the question of reorganising the management at Buenos Ayres, and for this purpose Mr. W. G. Anderson, a well-known gas engineer in this country, was sent out. They had been able to secure the larger part of the coal which the Company would require in the current year at a very large reduction compared with the figures appearing in the present accounts. A revaluation had been made of the whole of the property, and it would be gratifying to the shareholders to learn that an increased value of nearly £100,000 was shown. About £300,000 of the Company's capital was invested in a very efficient and profitable electric light undertaking, the earnings of which, separately, would well justify a somewhat better dividend than that declared by the directors upon the whole undertaking, but they had felt that it was more prudent to retain the balance in hand. Although no increase had been shown in the past year in the sale of gas, there had been an advance of about 8 per cent. in the sale of electricity.

Mr. W. W. Phipps seconded the motion, which was agreed to unanimously.

ENGLISH ELECTRO-METALLURGICAL.

Presiding over the annual meeting of this Company at Salisbury House, E.C., the **Marquis d'Hautpoul** said the Company had been upon a commercial basis since the month of January, and was gradually increasing its output and extending its connections. The manufacture proceeded without the smallest hitch, and from that he thought they owed their acknowledgments to their colleagues who had brought to Leeds the best of their experience at Dives, and had produced works which already demonstrated considerable advantages over the original from which they had been copied. At the present moment their output was on the basis of 25 tons gross per week, but they were really ready for a turnover of 60 tons. The most important field for their tubes was in the construction of steamships, but for that they required the Board of Trade's certificate as regarded the mercantile marine, and to be accepted on the list of the Admiralty as regarded men-of-war. The Inspector of the Admiralty had tested and approved of their tubes, and for all practical purposes they were placed upon the official list. For steam-pipes, both on the Admiralty list and for the mercantile marine, they had still to await the Board of Trade tests, which began a fortnight ago. They hoped then to obtain an almost immediate augmentation of business. The copper market had got upon a more normal basis, which was of great importance to the Company. Under the advice of their managers the Board had decided to add a small plant for making brass tubes. The plant would be capable of turning out about 80 tons a month, and would greatly facilitate them in taking orders from firms who required supplies both of copper and brass goods.

Mr. A. Demmler seconded the motion for the adoption of the report, which was agreed to.

A resolution was also passed changing the name of the Company to the Leeds Copper Works, Limited.

Digitized by Google

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Shanghai.—The last day for receiving tenders for the proposed municipal tramway and motor 'bus service is June 30.

Beckenham.—The Electric Lighting Committee invite tenders for the supply of incandescent lamps. Tenders by June 6. Details in our advertisement columns.

Dudley.—The Electric Lighting Committee invite tenders for the supply of incandescent lamps and oil. Tenders by June 6. Details in our advertisement columns.

Poplar.—The Electricity Committee invite tenders for the supply of about 130 cast-iron arc lamp columns. Tenders by May 28. Details in our advertisement columns.

Christiania.—The Government Telegraph Department, 14, Karl Johansgade, require tenders for about 60 tons of wire and a large number of insulators. Tenders by May 21.

Poplar.—The Electricity Committee invite tenders for the supply of special armoured cable, suitable for laying under water. Tenders by May 28. Details in our advertisement columns.

Glamorgan.—Tenders are invited for wiring and fittings at Parc Gwyllt and Angelton Asylums, near Bridgend, Glamorgan. Tenders by May 31. Details in our advertisement columns.

Valparaiso.—The Municipality are inviting tenders for electric lighting and tramways. We understand that particulars may be obtained from the Chilian Consul. Tenders by Sept. 1.

Hull.—The Corporation invite tenders for the supply of 20,000 cast-iron holding-down plates (weight, about 42 tons). Full particulars may be obtained at the City Engineer's Office. Tenders by May 30.

Oldham.—The Electricity Committee invite tenders for supplying the cables, troughing, bitumen, and insulators comprised in contract No. 6. Tenders by May 20. Details in our advertisement columns.

Barking.—The Urban District Council invite tenders for motors, pipework, chequer plating, etc. Full particulars may be obtained from the Engineer, Electricity Works, East Barking. Tenders by June 6.

Brighton.—The Town Council invite tenders for the supply of 300 tons of steel girder tramrails. Specifications, etc., may be obtained from Mr. Thos. B. Holliday, tramways engineer, Lewes-road, Brighton. Tenders by June 9.

Bedford.—The Electricity Committee invite tenders for the supply and delivery of economisers. Specification, etc., can be obtained from the Borough Electrical Engineer, Cauldwell-road, Bedford. Tenders by May 17.

Manchester.—Messrs. W. T. Glover and Co., Limited, of Trafford Park, Manchester, invite estimates from makers of electrical transformers for a transformer to give 150,000 volts for cable testing. Particulars on application.

Glasgow.—The Corporation invite tenders for one economiser, with induced-draught fan, and condensing plant. Particulars may be obtained from Mr. W. A. Chamen, the engineer, 75, Waterloo-street, Glasgow. Tenders by June 7.

Bury (Lancs.).—The Electricity Committee invite tenders for the supply and erection of jet condenser and pumps. Specification, etc., may be obtained from Mr. S. J. Watson, engineer and manager, Electricity Works, Bury. Tenders by May 20.

Coventry.—The Electric Light Committee invite tenders for the supply and erection of steam and water pipes and accessories. Particulars may be obtained from the Electrical Engineer's Office, Electricity Works, Coventry. Tenders by May 26.

Stockport.—The Gas and Electricity Committee invite tenders for supply of one water-tube boiler for their electricity station at Millgate. Specifications, etc., may be obtained from the engineer, Mr. S. Meunier, Gas and Electricity Office, Portwood. Tenders by May 21.

West Ham.—The Corporation invite tenders for the construction of about eight miles of route length of tramways. Specifications, etc., may be obtained from the offices of Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster. Tenders by June 10.

Brighton.—The Town Council invite tenders for the supply of points, crossings, tiebars, bolts, and other fittings. Specifications, etc., may be obtained on application at the office of Mr. Thos. B. Holliday, tramways engineer, Lewes-road, Brighton. Tenders by June 9.

Burton-upon-Trent.—The Corporation invite tenders for the supply and erection of three 100-kw. high-speed tramway generators and switchboard, and three Lancashire boilers, steam-pipes, jet condensing plant, economiser, and accessories. Tenders by May 30. Details in our advertisement columns.

Warrington.—The Health Committee invite tenders for the wiring and installation of electrical fittings at the infectious diseases hospital, Monk-street. Specifications, etc., may be seen and all further information obtained from the Borough Surveyor, Town Hall, where tenders must be delivered by 4 p.m. on 21st inst.

Manchester.—The Tramways Committee invite tenders for the supply of cast-iron bases, collars, and finials for tramway poles; and tramway rail bonds. Specification, etc., may be obtained from Mr. J. M. M'Elroy, general manager, Tramways Department, 55, Piccadilly, Manchester. Tenders by May 24.

Govan.—The Council invite tenders for fuse boxes for house services, meters (not electrolytic), demand indicators, manhole boxes and connections, and joint-boxes for armoured cables. Particulars may be obtained from Mr. J. Brown, resident electrical engineer, Electricity Works, Govan. Tenders by May 27.

Astrachan.—Erection of electric generating station and installation of public and private lighting, commencing with 150 arc and 6,000 incandescent lamps. Manufacturers who will undertake to finish the work within two years can obtain particulars from the Municipality. Agents will not be able to tender. Tenders by June 7-20.

Edinburgh.—The Town Council invite tenders for the wrought-iron pipework in connection with the electric lighting of the north-west extension of the City Chambers. Specification, etc., can be obtained at the office of the Resident Electrical Engineer, Electricity Supply Station, Dewar-place, Edinburgh. Tenders by May 17.

Blackpool.—The Corporation invite tenders for the supply and delivery of about 250 tons of slightly defective new or good second-hand steel flat-bottomed rails, about 75lb. per lineal yard, together with fishplates, bolts, and wrought-iron spikes. Specification, etc., may be obtained from Mr. John S. Brodie, A.M.I.C.E., borough engineer, Town Hall, Blackpool. Tenders by May 20.

Swindon.—The Corporation invite tenders for the supply, delivery, and erection at the electricity works, Swindon (Wilts), of 252 accumulator cells and accessories. Specification, etc., may be seen at the offices of the engineers, Messrs. Lacey, Clirehugh and Sillar, 78, King-street, Manchester, and at 2, Queen Anne's-gate, Westminster. Tenders by May 19. Details in our advertisement columns.

Worthing.—The Corporation invite tenders for the supply and erection of one 250-kw. steam dynamo (continuous-current dynamo direct-coupled to a vertical enclosed high-speed engine), and one dry-back marine type boiler, with fittings. The specifications, etc., can be inspected and all information obtained at the offices of Messrs. Burstall and Monkhouse, 14, Old Queen-street, Westminster, S.W. Tenders by May 26.

RESULTS OF TENDERS.

Cardiff.—The Corporation have accepted the tender of Dick, Kerr, and Co. for 20 double-deck double-bogie and 20 double-deck single-truck cars.

Peterborough.—The tender of McKenzie Bros., of Edinburgh, for the supply of arc lamp pillars for electric street lighting, at £445, has been accepted.

Morley.—The Town Council have accepted the tender of the Morley Electrical Engineering Company for supply of two electrical exciters at £104. 2s.

Electrical Plant for South Africa.—The Koffyfontein Mines, Limited, have placed an order with Dick, Kerr, and Co. for complete electrical plant for haulage and lighting at the mines.

Nelson.—The Town Council have accepted the following tenders for the construction of the light railways: R. Blackwell and Co., overhead equipment, £1,660. 18s. 9d., and rails, etc., £5,525. 7s.

Electric Launches.—The Thames Electric Launch Company, Weybridge, have a number of important orders for electric launches in hand for private owners on the Thames, one for use in the Bay of Naples, and an electric pinnace for the Natal Government.

Luton.—The Town Council have accepted tender B of the St. Helens Cable Company, Warrington, for the supply and delivery of distributing cables or mains, at £250. 16s. 4d.; 10 tenders were received. The wiring of the town hall has been carried out by Taylor and Co., at £98. 2s. 5d.

Holwell Ironworks, Asfordby.—This company have placed their order with the Electrical Company, Limited, 122-124, Charing Cross-road, W.C., for erection of a power plant at their extensive works. The tender of Belliss and Morcom, Limited, has been accepted for two 220-h.p. engines.

Broughty.—The Town Council have accepted the following tenders for machinery: Belliss and Morcom, Birmingham, one 60-kw. engine and dynamo and one 30-kw. engine and dynamo, together with spare armature for the larger set and spare parts for both engines, £1,280; and Cooper and Greig, Dundee, for condensers and pumps, £456.

Kensington.—The following tenders have been received for installing the electric light in Warwick-road stables in accordance with the specification prepared by the lighting engineer—viz.: A. Grundy, £379. 10s.; J. E. Spagnoletti and Co., £340; H. Nash, £275. 10s.; Chard and Co. £249; C. Oliver and Co., £205. 10s. 6d. (accepted).

Sheffield.—Messrs. Cravens, Limited, Darnall, have secured the contract for 20 double-deck cars, at £12,800, to be supplied with Hadfield's wheels. The tender of Cole, Marchent, and Morley has been accepted for the supply of one 1,000-kw. generator for the new engine, at £3,200, the firm to be allowed to sub-let to the British Thomson-Houston Company.

Rathmines.—The Council have accepted the following tenders for the extension of the electricity supply works and mains: Dick, Kerr, and Co., one 300-kw. steam dynamo, pipework, and accessories (with Willans engine), £3,547. 10s. 8d.; Kelvin and J. White, Limited, extension of switchboard, £174; British Insulated Wire Company, Limited, supply mains, schedule rates for various cables.

Elland.—The District Council have accepted the following tenders for the plant of the proposed electricity works for the district: Belliss and Morcom, Birmingham, engines; Greenwood and Batley, Leeds, dynamos; Ashmore, Benson, Pease, and Co., Stockton-on-Tees, storage battery; H. H. Wright, Halifax, switchboard; J. Hitchin and Son, Halifax, crane; Anchor Cable Company, Leigh, cables; Thornton and Crebbin, Bradford, condensers.

Hammersmith.—The estimate for the Hythe-road extension work includes three transformer boxes for distributing network, at £60 each. Prices have been obtained from the following firms—viz.: Siemens Bros. and Co., Woolwich, £79 each; Electrical Construction

Digitized by Google

Company, Wolverhampton, £70 each; and Ferranti Limited, Hollinwood, £36 each. Messrs. Ferranti have not quoted for the same size box as the other firms, but for their standard pattern. The box is the same size as those at present in use, and three transformer boxes will be purchased from Messrs. Ferranti at the quoted price, and three 50-kw. transformers for working in same at the price of £80. 10s. each.

Cables.—We are informed that the British Insulated Wire Company have received during the past few days orders for cables as undermentioned: Ashton-under-Lyne, extensions; Brompton and Kensington Electrical Supply Company, extensions; Farnworth Urban District Council, extensions; Kensington and Knightsbridge Electric Supply Company, extensions; Dublin Corporation, further considerable extensions; Harrogate Corporation, extensions; Chesterfield Corporation, extensions; Portsmouth Corporation, extensions; Brighton Corporation, extensions; Jarrow and South Shields, tramway cables for the British Electric Traction Company; Ogmore Valley Electric Company, extensions; Glasgow Corporation, telephone cables, further considerable extensions; Willesden, extensions.

Heckmondwike.—The Electric Lighting Committee have received tenders for the supply and erection of the following plant for the extension of the electricity works: (Section A) steam, water, and exhaust piping, etc.; (B) steam traction generator; (C) storage battery and automatic reversible booster; (D) alterations and extensions to main switchboard; (E) condenser and oil separator; (F) water-cooling tower; (G) underground traction and return feeders. Accepted tenders: (Section A) Thornton and Crebbin, Hammerton-street Ironworks, Bradford; (B) Dick, Kerr, and Co., with a Howden engine; (C) Chloride Electrical Syndicate, Clifton Junction; (D) Bertram Thomas, Pulme, Manchester; (E) Thornton and Crebbin; (F) Worthington Pumping Engine Company, Manchester; (G) W. T. Henley and Co., London.

Salford.—The Electric Light Committee have accepted the tenders of the following firms for the annual supply of materials: Belliss and Morcom, Limited, crank chamber oil, 1s. 4d. per gallon; A. Kenyon and Co., cement for joint rings, 7d. per lb.; J. Wrigley, sponge cloths 7d. per gross, best white waste 30s. per cwt., coloured waste 18s. per cwt.; A. Kenyon and Co., packing, at a schedule of prices; J. Smith, rubber insertion, 1s. 4d. per lb.; General Electric Company, rubber solution, tape and wires, at a schedule of prices; Siemens Bros. and Co., Limited, rubber strip and mica sheets, at a schedule of prices; Johnson and Phillips, copper strip, 11d. per lb.; Baxendale and Co., solder and plumber's metal, at a schedule of prices; W. T. Glover and Co., Limited, compound for joints, £2. 6s. 8d. per cwt.; G. Forest, cast-iron boxes 8s. per cwt., frames and covers 7s. per cwt.; G. Clarke and Sons, tee-joint boxes 18s. each, straight-joint boxes 14s. each; Lloyd and Lloyd, wrought-iron pipes and bends, at a schedule of prices; Staveley Coal and Iron Company, Limited, cast-iron pipes and bends, at a schedule of prices; W. Higgins and Son, bricks, at a schedule of prices; Place and Sons, earthenware pipes, 6½d. per yard; Doulton and Co., earthenware specials, at a schedule of prices; Howard Conduit Company, troughing, at a schedule of prices; Albion Clay Company, conduits, at a schedule of prices; Baxendale and Co., buckets, screws, bolts and nuts, steel wire, and shovels, at a schedule of prices; W. Shorrocks, brushes, etc., at a schedule of prices; J. Smith, sheet lead, lead piping, and block tin, at a schedule of prices; Wingfield and Co., paints, oils, soft soap, and sundries, at a schedule of prices. The "deferred payment purchase system" for the wiring of consumers' premises submitted by F. W. Smith and Co., Limited, has been adopted.

BUSINESS NOTES.

TRACTION.

Berlin.—Yesterday the first Pan-American Automobile Exhibition was opened here.

Plymouth.—It is hoped to have the electric cars running to the promenade pier very shortly.

Kirkintilloch.—The Corporation of Glasgow have promised to consider a proposal to run a tramway to this place.

Aberdeen.—It is expected that the Queen's Cross and Bayview section of the tramways will be opened for traffic very shortly.

Belfast.—The Corporation have now definitely decided to oppose the Cavehill and Whitewell Tramways Bill in the House of Lords.

Sheffield.—The City Council have agreed to make a loan of £16,000 out of the tramway profits towards the Angle-street building scheme.

Fraserburgh.—Preparations are being made for making a start with the construction of the Fraserburgh and St. Combs light railway.

Birkenhead.—The Tramways Committee have been authorised to lay a second track in Balls-road between Woodchurch-road and Slatey-road.

North Metropolitan Tramways.—Plans for the electrification of the above tramways have been deposited by the London County Council with the company.

Swansea.—The Light Railway Commissioners will open a local enquiry to-day into the scheme for constructing a light railway between Morriston and Pontardawe.

Colchester.—Messrs. Kennedy and Jenkin have been retained to advise the Town Council in the matter of the construction of tramways under the Colchester order.

Ainsdale.—The Parish Council have decided to approach the Birkdale Urban District Council with a view to getting an extension of the tramways to Ainsdale.

Batley.—An agreement has now been come to between the Corporation and the British Electric Traction Company respecting a lease to that company of the local tramways.

Dingwall.—Information has been received to the effect that the order for the Cromarty and Dingwall light railway has been passed without amendment by the Board of Trade.

Yarmouth.—It is hoped to have the electric cars running on some of the sections of the new tramways in June. The working of the lines on Sundays has already been agreed to.

Rotherham.—The Corporation have appointed a sub-committee with power to approach the Sheffield Corporation and enter into negotiations for a working agreement with respect to tramways.

Cardiff.—The Town Council on Monday reversed the decision come to at the last meeting not to run trams on Sundays, and it was resolved to run the cars on Sundays between the hours of 2 and 10 p.m.

Morley.—The British Electric Traction Company have the arrangements well in hand for proceeding with the laying of the tramways at this place. The plans are now nearly ready for submission to the Town Council.

North Staffordshire.—The North Staffordshire Tramways Bill, which had already received the sanction of the House of Commons, passed through its committee stage in the House of Lords on Tuesday without opposition.

Crewe.—The Town Council have rescinded their resolution to promote a light railway scheme for the borough, on the ground mainly that the recent poll of the townspeople did not truly represent the popular feeling in the matter.

London United Tramways Bill.—It has been officially notified that the London United Tramways Bill is to be considered on Thursday, May 29, by a committee of the House of Commons presided over by Mr. Compton Rickett.

Hastings.—Several additions are being made to the motorcar services at Hastings, which would indicate that this style of vehicular communication with the outlying districts is much appreciated by the residents and visitors to the town.

Handsworth.—The District Council propose to give notice to the South Staffordshire Tramways Company that they propose acquiring that portion of the company's system within the Handsworth boundary within a certain period.

Bordeaux Electric Tramways Co.—The dividend of 5fr. for 1901 is now payable, and registered certificates, coupons, and drawn shares can be deposited with the Comptoir Nationale d'Escompte de Paris, at 52, Threadneedle-street, E.C.

Kensington.—The Law Committee recommend that they be vested with authority to take "all such action as may be deemed expedient in the best interests of the borough" in regard to the Central London Railway and the London United Electric Railway Bills.

Aston.—The District Council are applying to the Board of Trade for sanction to an expenditure of £24,516 for the electrical equipment of tramways, being part of a sum of £65,000 in respect of which an application has already been made to the Local Government Board.

Deanhead Light Railway.—Amongst the light railway orders recently confirmed by the Board of Trade is the Deanhead Light Railway Order, 1902, authorising the construction of a light railway in the county of York, from Stainland-with-Old Lindley to Greetland.

Nelson.—The Tramways Committee recommend the Town Council to support the application of the promoters of the Colne and Trawden Light Railways Order, 1901, so as to empower the promoters and the Corporation to enter into agreements for working their respective light railways.

Doncaster.—The proposed new tramways will run to Bentley, Balby, Hexthorpe, Wheatley, Hyde Park, Avenue-road, and the Race Common. Contracts for the various works have been let, and it is expected that the lines to Blaby and Hexthorpe will be the first to be opened.

Cheltenham.—A final agreement has now been arrived at between the Corporation and the Cheltenham and District Light Railway Company concerning both the existing line and the proposed extensions, which are to form the subject of the Light Railway Commissioners' enquiry this week.

Southend.—On Thursday last week the Light Railway Commissioners opened an enquiry into the application of the Railways and General Construction and Maintenance Company, Limited, for an order authorising the construction of the Southend, Bradwell, and Colchester light railway. The estimated cost of the scheme is about £300,000.

Lowestoft.—Mr. Hawtayne, the Council's consulting electrical engineer, has completed the plans and specifications for the laying of the tramways. The inside of the track is to be laid with basaltic lava, with an outside margin of granite setts. The Council are in negotiation with the Prudential Assurance Company with regard to a tramway loan of £250,000.

Wigan.—The Council have sealed an agreement between the Corporation and the Wigan and District Tramways Company, Limited, for the sale of the company's undertaking to the Corporation upon the terms already arranged, and also a conveyance from the Corporation to the Pemberton Urban District Council of so much of the tramways undertaking as is situate in that township.

Scarborough.—At the request of the promoters of the Scarborough Tramways Bill, which has now passed its third reading, the Corporation have agreed to apply to the Commissioners of Woods and Forests for their consent to the construction of tramways across the new marine

Digitized by Google

drive round the castle foot. The drive, which is now in course of construction, will connect the north and south promenades.

Liverpool.—A Liverpool gentleman has recovered £150 damages for personal injuries from the Corporation. He was boarding an electric tramcar at the pier head in July last, when, as he alleged, the car was improperly started by the conductor, with the result that his foot missed the step and he was dragged by the car for some distance, and finally his foot was run over and so severely injured that it had to be amputated.

Newcastle.—A commencement has been made with the erection of the trolley wires along Clayton-street. A meeting has been arranged between the Corporation tramways manager and the representatives of the trades union to consider the alleged grievances of the tramways employés. It is stated that in consequence of the proposed extension of the tramways further into Gosforth the capacity of the power-house will require to be increased.

Liverpool Overhead Railway.—A fire, which fortunately was not of a serious nature, occurred on a train on the Liverpool Overhead Railway on Tuesday night. Shortly after 10 o'clock the end of a train at Toxteth Dock Station was discovered to be on fire. The brigade from the dock was summoned, and the outbreak was extinguished in the course of a few minutes before much damage had been occasioned. There were no passengers in the train.

Wolverhampton.—The new electric tramway to Tettenhall is expected to be opened one day this week as far as the Half-Way House. It is reported that on Saturday last two horses at different times sustained severe shocks by coming in contact with one of the studs forming part of the Lorain surface-contact system in Darlington-street. It is stated that the box in question got out of order, but within half an hour the defect was put to rights again.

Shields and Sunderland Tramways.—The Select Committee of the House of Lords of which the Duke of Northumberland is chairman have found the preamble of the Bill promoted by the British Electric Traction Company to obtain parliamentary sanction to the construction of tramways in South Shields and from that place to Sunderland not proved. The chief opposition to the Bill came from the South Shields Corporation and the North-Eastern Railway Company.

Saddleworth.—The Select Committee of the House of Commons presided over by Lord Glenesk have passed the preamble of the Bill promoted by the Saddleworth and Springhead Tramway Company, one of the objects of which is to connect Saddleworth with Oldham and Mossley, and thereby effect a junction with Manchester. In announcing the decision of the committee, the Chairman said that, if required, the company must sell portions of their undertaking on Board of Trade terms.

Edinburgh.—The negotiations between the Corporation and the Edinburgh and District Tramways Company, Limited, for the settlement of the dispute as to the payment of the rent have unexpectedly fallen through. A proposal was formulated at a private meeting of the Town Council on Tuesday to take proceedings for the recovery of the full amount due by the tramway company, but this was negatived and it was left in the hands of the Lord Provost's Committee and the town clerk to take further proceedings.

Nottingham.—The Corporation Bill, which is to authorise the Corporation of Nottingham, among other things, to construct additional tramways at a cost of £87,500, was before Lord Morley's Committee as an unopposed measure on Tuesday. Eventually the proposed clauses were allowed to go through for the third reading stage, but the formal report was kept back for further consideration with reference to a clause at the instance of the Postmaster-General for the protection of the telegraphic wires.

Southport.—The borough surveyor and the electrical engineer have been instructed to prepare plans and estimates for laying down and equipping the new tramways in Shakespeare-street, Duke-street, Cemetery-road, and Ash-street. The borough treasurer reported at the last meeting of the Town Council that the cost of reconstruction of the lines leased to the Southport Tramways Company, Limited, had been £60,979, and it was resolved that the town clerk be instructed to complete the new lease of the lines to the company.

Private Bills.—In the House of Lords the following Bills have been read a third time: Northumberland Electric Tramways Bill, Newcastle-upon Tyne Electric Supply Bill, Newcastle-upon-Tyne Corporation Tramways Bill, and Cornwall Electric Power Bill. In the House of Commons the following Bills have been read a third time: Metropolitan District Railway Bill, Norwich Corporation (Electricity, etc.) Bill, the Scarborough Tramways Bill, and the Garston and District Tramways and Electric Supply (Transfer) Bill.

Middlesbrough.—The Board of Trade have forwarded the Corporation a copy of revised regulations proposed to be made by them with respect to the use of electrical power on the overhead trolley system of the Imperial Tramways Company. The Hackney Carriage Committee have replied, requesting the Board of Trade to amend the first clause so as to provide for a speed indicator to be fixed in a conspicuous place in each car, open to the public view, and also to add a clause providing for lifting jacks to be carried on each car.

Huddersfield.—Major Druitt, of the Board of Trade, on Wednesday inspected further routes of the Corporation tramways which have been converted for electric traction—viz., the Waterloo, Mold Green, and Stile Common. With these Major Druitt expressed satisfaction, and the lines were forthwith opened for traffic. The Fartown and Sheepbridge sections are practically completed, and will no doubt be opened shortly. It is expected that the whole of the remaining sections will be ready for the electric cars by the beginning of July.

Paris Metropolitan Railway.—The annual general meeting of the Paris Metropolitan Railway Company was held a few days ago in Paris. The total traffic receipts and revenues from side sources, such as advertising and bookstalls, amounted for the year 1901 to £342,008, and the total working expenditure to £161,263. The gross profits, amounting to £180,735, were apportioned as follows: proportion to the city of Paris, according to the terms of the concession, £111,125; company's net profits, £69,610. The dividend voted was 15fr. per share.

Wealdstone.—The following resolution has been passed by the Urban District Council: "That having regard to the rumours abroad in the district that the route of the proposed line of light railway from Harrow will be along Headstone and Harrow View roads, thus practically omitting Wealdstone from the scheme, the County Council of Middlesex be asked to reconsider the whole question, and to arrange in their scheme for the route to be along the main (Station) road and through the High-street, Wealdstone, as proposed in the former scheme."

Ettrick Bay.—The order for the electric tramway promoted by the Rothesay Tramway Company came before the Parliamentary Committee on Friday last in Edinburgh. The order comprises a tramroad two miles three furlongs in length, practically the whole of which will be a double line, commencing at Port Bannatyne, and terminating about 400 yards east of Drumachloy Bridge. Power is also sought to acquire land for a generating station, and for carsheds, the former in Rothesay and the latter in Ettrick Bay. There being no opposition, formal evidence was given proving the preamble, and the order was duly passed.

Eccles.—Last Friday saw the opening for traffic of the first portion of the electrically-equipped tramways. Previously to this the electric cars had only run to the Salford boundary at Ladywell sanatorium, but on the completion of the negotiations and arrangements with the Eccles Corporation the work of extension was proceeded with with commendable promptitude, and within a period of 18 days over a mile of single track, together with its accompanying overhead equipment, had been completed. Thus early on Friday morning the first car, set apart for working-men, was enabled to leave Eccles Town Hall and proceed to Salford and Manchester.

Presentation.—The assistant engineer of the Blackburn tramways, Mr. C. Barber, who has been appointed to the position of works engineer and traffic manager of the Bournemouth Corporation tramways, before leaving Blackburn was presented by the staff and employés of the tramways department with a gold albert, silver cigarette-case, etc. Mr. Giles, in making the presentation, spoke very highly of the way Mr. Barber had carried out his duties, and of the great esteem in which he was held by all the staff. Mr. Barber, in a few well-chosen words, thanked the staff very sincerely for the handsome presents and for the kind feeling that had been shown him during his stay in Blackburn.

London County Council.—Last week we noted in these columns that the Council had acquired the old property of the Gaslight and Coke Company at Pimlico as a site for a generating station in connection with the Council's southern tramways. There now seems to be some doubt as to whether the Council have the power to utilise the site for this purpose, and at their usual weekly meeting on Tuesday the Parliamentary Committee reported that as a matter of emergency they had given the necessary instructions for obtaining powers in the present session of Parliament to enable the Council to build a generating station on the land in question. It is thought that there is still time before Parliament is prorogued to get a Bill through for this purpose.

Dundee.—At a recent meeting of the Tramways Committee on the subject of the kind of cars to be used, Prof. Kennedy reported the result of the negotiations he had already had with the Board of Trade on the subject of the type of car, from which it appeared there was little hope that the Board would consent to the use of the double-decked car already agreed upon. Prof. Kennedy having also made explanations in regard to the different types of car, it appeared to the committee there was no help but to adopt the single-decked car in the event of Prof. Kennedy failing to get the Board of Trade to pass the double-decked car already agreed upon by the Council. It was, however, resolved to make one more effort to get the Board of Trade to sanction the double-decked cars.

Manchester.—The Stockport-road route of the Corporation tramways is now finished, and will very shortly be opened for traffic. At the monthly meeting of the Davyhulme Parochial Committee on Friday plans were submitted of a proposal for the construction of a system of tramways which will connect Barton Bridge with Glossop. It is intended to promote the scheme in the next session of Parliament. The tramways embrace the following places: Northenden, Cheadle and Gatley, Bramhall, Poynton, Hazel Grove, Marple, Ludworth, Chisworth, Charlesworth, Mottram, Broadbottom, and Glossop. The Davyhulme Parochial Committee offered no objection to the proposed tramways, but the plans have yet to be submitted to the Parish Council for acceptance.

Bradford.—The Wakefield-road section of the Corporation tramways was opened for traffic yesterday. Good progress continues to be made with the conversion of the other tramways from steam traction to electric traction. The section between Rawson-square and the grammar school has been in great measure relaid, and the posts erected for the support of the overhead equipment, and a few days will see the junction finished with the completed line in Manningham-lane. The section of the line from Manningham-lane to the North Park gates and on St. Mary's-road has also made much progress, a great deal of the work being already completed. On the Otley-road route poles have been erected for the support of the overhead equipment, but the lines have yet to be relaid and bonded. A start has also been made with the laying down of the new line to Little Horton.

Yeadon.—At the last meeting of the District Council Mr. G. H. Teale reported upon an interview which he had had with the representatives of the syndicate who are proposing to lay a tramway through

Digitized by Google

the district. He was told that the project was not yet matured, but the syndicate had in view the laying of a tramway from the Leeds boundary at Kirkstall, through Horsforth, Rawdon and Yeadon to Guiseley Green Bottom, and up Park-road, down Hollings Hill, through Shipley and Bingley to Keighley. In conjunction with the tramway it was also proposed to supply electricity for lighting and motor purposes in the district through which the tramways were run. The deputation were also told that the syndicate would be able to supply electric light at a cheaper rate than the price now charged for gas in the Yeadon district. The syndicate promised that when the scheme was matured they would attend before the respective councils and lay it before them.

Wrexham.—The tramways company propose to make certain alterations in connection with the making of the proposed line, including the substitution of a single for a double-single line in Regent-street, between Cathrall's-lane and Duke-street; and also the substitution of a double for a single line down Vicarage-hill for the safety of traffic, owing to the many turnings in the road. The committee of the House of Lords presided over by Lord Glenesk has had under consideration the Bill promoted by the Wrexham District Tramways Company, the object of which is to extend the authorised tramway from Wrexham to Rhosllanerchrugog so as to carry passengers further in the latter place to a point near Rhos Station. The only opponents to the scheme were the Great Western Railway Company, who have a branch line between the two places. It was stated that the tramway company had now passed into the hands of the British Electric Traction Company. After hearing evidence the committee found the preamble proved.

Clacton.—The Corporation have before them an offer from the British Electric Traction Company to promote a scheme of electric tramways in the district. The Light Railway Commissioners held a public enquiry on Wednesday, May 7, into the application for an order to authorise the Clacton and St. Osyth light railway. The chief objection lodged was that by the Clacton Council with regard to the conveyance of goods. They desired that no goods, cattle, or other trucks should be run on the railway. The Rural District Council and the St. Osyth Parish Council were, however, in favour of the carrying of goods. The promoters were prepared to make any reasonable concession so far as regards time and offensive goods were concerned. The estimated cost of the scheme is £36,987, providing for about 4½ miles of line. With reference to the Council's application to the Local Government Board for permission to let a portion of the cliffs for the proposed electric stairway, a letter has been received from the Local Government Board declining to interfere in the matter, and it is stated that the company are now proceeding with the work.

Stockport.—By an agreement entered into between the Corporations of Stockport and Hyde, Bredbury and Romiley Council, and the Oldham and Hyde Electric Tramway Company, the Stockport Corporation will provide a service of cars between Lancashire Bridge, Stockport, and the Market-place, Hyde, and the company between Market-place, Hyde, and St. Mark's Church, Bredbury. For a period of 12 months from the opening of the tramways the Stockport Corporation and the company shall be entitled to run a service of cars at intervals of not less than 10 minutes, the company over the lines of the Corporation to St. Mark's Church, Bredbury, and the Stockport Corporation over the lines of the company in Hyde. After the expiration of 12 months this provision shall be subject to revision, and in default of agreement settled by arbitration. The Stockport Corporation and the company are each to charge the full authorised fares upon the tramways, with certain fixed through fares. The question of the acquisition by the Corporation of the Stockport and Hazel Grove tramways has been considered at several meetings of the Tramways Committee, but no action has as yet been taken in it.

Camberwell.—At the meeting of the Borough Council on Wednesday the Finance Committee reported the receipt of a letter from the St. Pancras Borough Council stating that an attempt is being made in the House of Commons to amend Standing Order No. 22, the effect of which would be to abolish the veto vested in the local and road authorities in regard to the construction of tramways. A similar attempt was made in the House of Lords last year, when the Camberwell Council, having regard to the fact that the London County Council had become the authority for the tramways and would in future be the largest owner, passed a resolution in favour of the alteration of the parliamentary Standing Orders relating to Tramway Bills promoted by a municipal authority, but that the veto at present vested in local and road authorities should be retained where Tramway Bills are promoted by private companies. St. Pancras urges that combined action should be taken by the metropolitan borough councils to prevent their powers of veto in this respect being taken away. The committee recommended the Council to adhere to their previous resolution referred to above.

Paisley.—At the meeting of the Town Council on Tuesday a communication was submitted from Mr. W M. Murphy in reply to a request by the Town Council that before embarking on any expenditure for supplying the tramways with electricity they should be assured of a minimum annual demand of 500,000 units, and that if the generating machinery was ready before the tramways interest and sinking fund should in the interval be paid on their expenditure. In his reply Mr. Murphy declined to come under any obligation on these points, and stated that if the Corporation desired to be relieved of the liability to supply the company with electricity he was willing to entertain such a proposition. He also stated that he thought it right to add that he only counted on the line from Hawkhead to Johnstone being opened in the first instance, and that the electricity required for that line would be about 200,000 units per annum. After considering Mr. Murphy's letter, a report was prepared by the electric lighting convener (Mr. Fisher) and the engineer (Mr. Parkinson), in which they recommend the laying down meantime of plant to supply the tramways with 250,000 units per annum, the estimated cost being £8,500.

Embankment Tramways.—On Tuesday the Select Committee of the House of Commons charged with the consideration of the London County Council Tramways and Improvements Bill concluded their enquiry so far as the proposal for a tramway along the Embankment is concerned. After conferring in private, the chairman announced that the committee had come to the conclusion unanimously that the tramway should be authorised from Westminster Bridge to Waterloo Bridge. They proposed, however, to ask the promoters to bring up an arbitration clause for the protection of the District Railway. The effect of the decision is to enable the County Council to practically join up their southern and northern tramway systems by way of the underground line they propose to build under the new street from Waterloo and Strand to Holborn. The committee on Wednesday proceeded with the consideration of the other parts of the Bill, and in the result decided to approve each of the tramway proposals. They, however, required the insertion of a clause to carry out the suggestions for providing a more convenient terminus for the Putney line in the Lower Richmond-road, and they also struck out the clause giving power of contribution to the boroughs of Lambeth and Deptford. The committee then proceeded to consider the proposal for the widening of Hampstead-road at its junction with Tottenham Court-road.

Croydon and District Electric Tramways Bill.—This Bill has been before the committee of the House of Commons presided over by Mr. Compton Rickett for several days, being promoted by the British Electric Traction Company, with the approval of the Croydon Corporation. The company are lessees, under the Corporation, of the present Croydon tramway system between Norbury and Purley, and the proposals in the Bill include an extension to Waddon, Wallington, Carshalton, and Sutton. From Sutton continuations are proposed to Belmont and to Mitcham, where junction with the Mitcham light railway is contemplated, and communication with the London County Council system at Tooting. Another line is projected to Beddington, and it is proposed to extend the existing tramway to Penge and the Crystal Palace. Petitions against the Bill from frontagers on the lines of route, from the Surrey County Council in respect to matters in connection with main roads, and from the London, Brighton, and South Coast Railway Company on engineering details were represented by counsel, and a considerable amount of local evidence was given. On Wednesday the committee sanctioned the proposals, with the exception of the Carshalton and Wallington portion of the South and West Croydon extension, and refused to the London, Brighton, and South Coast Railway control over the connection at West Croydon.

LIGHTING AND GENERAL.

Bootle.—A number of proposed extensions have been brought to the notice of the Electric Lighting Committee.

Harrogate.—The Council have resolved to ask sanction to borrow £46,000 for purposes of electric light extensions.

Halifax.—The Town Council are about to appoint a special committee to consider the whole question of lighting.

Salford.—Judge Parry has been asked to conduct the enquiry into matters appertaining to the electricity department.

Norwich.—The Norwich Corporation (Electricity) Bill has been ordered for the third reading in the House of Commons.

Morley.—Two additional transformers are to be ordered for use in Baker-street and Queen-street, at a cost not exceeding £79.

Derby.—At a special meeting next Tuesday the Corporation will take into consideration the question of private lighting in the city.

New Issue.—Letters of allotment for the issue of 45,000 shares in the South Wales Electrical Power Distribution Company have been posted.

Eton.—The Rural District Council have consented to the proposed electric lighting of Slough and Datchet, subject to the provisions made by Mr. Pelham.

Bury St. Edmunds.—During the past month applications for 362 8-c.p. lamps have been received, and 24 street lamps have been connected to the electricity mains.

Chesham.—The Urban District Council have returned, with certain amendments, the draft agreement between them and the United Electric Light and Power Company.

Accident.—It is reported that a young married man named John Flannigan, while at work at Glasgow electric power station last week, fell among some machinery and was killed.

Scarborough.—The Town Council on Monday confirmed the minutes of the Telephone Sub-Committee authorising application for a license for a municipal telephone system.

Berwick.—The proposal to establish a telephone circuit from Berwick to Coldstream, thence to Leitholm, Greenlaw, Duns, Chirnside, Reston, Coldingham, Ayton, Eyemouth, is being revived.

Cowpen.—The Urban District Council have decided to accept the suggestion of the Northern Counties Electricity Supply Company to tender for the lighting by electricity of Cowpen Colliery-square.

Ormesby (Yorks).—The Urban District Council are in communication with the Cleveland and South Durham Electric Power Company, Limited, with a view of obtaining a supply of electricity in bulk.

Heywood.—The Electric Lighting Committee at their last meeting considered a letter from Mr. W. P. Adams, M.I.E.E., as to the free-wiring scheme, and further consideration was deferred until the next meeting.

Carnarvon.—With reference to the order which is being promoted by the Council, it has been reported to the Town Council that the time for the presentation of objections to the order has expired, and none have been presented.

Digitized by Google

Glasgow.—A committee of the Chamber of Commerce have asked Sir Wm. Arrol to act in their interest and to call attention in Parliament this session to the desirability of extending the underground telegraph system to Scotland.

Hanley.—The Council will oppose the application proposed to be made by a syndicate anxious to establish a power scheme in the counties of Chester or Stafford. Several increases have been granted to the electricity works staff.

Worksop.—Several recommendations with a view to increasing the number of consumers and the extension of the cables are under consideration. It has also been decided to erect 75 new lamps in the public streets at a cost of £200.

Little Woolton.—Lieut.-Colonel A. C. Smith held an enquiry last week into an application by the Urban District Council to borrow £1,800 for electric lighting purposes. The current will be supplied by the Garston and District Electric Supply Company.

Harrogate.—The engineer's report and estimate as to the extensions required at the electric light station and street-lighting has been adopted, and application will be made for sanction to the borrowing of £46,000 for the carrying out of the works.

Heston and Isleworth.—The Electric Lighting Committee on Monday discussed electric lighting matters with Mr. Enright, their consulting engineer, and it was decided that a scheme should be prepared for the public and private lighting of the district.

Cryselco Arc Lamps.—We are informed by Messrs. Cryselco, Limited, Kempston Works, Bedford, that the increase in their business has compelled them to supplement their means of output by laying down a 100-h.p. Dowson gas generating plant with Crossley gas-engines.

Crook.—The Cleveland and Durham Electric Lighting Company are negotiating with the Urban District Council. The company propose to put in a power station at Witton Park or elsewhere, but the position of the station would depend upon the demand in each part of the district.

London County Council.—At the meeting on Tuesday it was agreed to lend the Battersea Borough Council £2,285 for electric lighting and the Shoreditch Borough Council £37,430 for electric lighting, street-lighting, and meters. A number of electric lighting mains notices were agreed to.

Brighton.—Great progress is being made with the works in connection with the erection of Brighton's electricity generating station, abutting on the foreshore at Fishergate. Messrs. Pedrette and Co., the contractors, have 16 engines in action, either working the crane or in use in pumping operations.

Newport.—Mr. Copland, the borough electrical engineer, has resigned. The working of the electricity works (for light) for the year ended March 31 last shows a total income of £12,422; works cost, £5,892; gross profit, £6,430; paid for interest and sinking fund, £5,571; and net profit, £859.

Hammersmith.—The loan of £7,295 for electric lighting from the London County Council has been completed. Since the last Council meeting 11 additional consumers have been connected, representing a maximum of 638 8-c.p. lamps, and the present number of consumers now taking current from the mains is 999.

Colne.—The electrical engineer's last monthly report showed that 2,745 units of electricity had been metered during the month, that 715 additional 8-c.p. lamps and eight arcs had been connected, and the maximum load on any day was 32 kw. The total number of units sold since the commencement of plant was 10,803.

"The Smart Set."—The June number of the *Smart Set* is just the thing with a roaring big fire, something hot to drink, and a pipe to get through these unseasonable Whitsuntide holidays. One might do worse than to start with "The Rebellion of May" as the most suitable to meet this special case. There are, as usual, a number of good things in the little volume.

Gravesend.—A a recent special meeting of the Town Council in committee, matters relative to the generating station buildings were discussed. The correspondence that had passed between the town clerk and Mr. Trentham was read, in which the engagement of Mr. E. J. Bennett to supervise the work of the new buildings was agreed, also the terms proposed.

Belfast.—Mr. H. M'K Sillars, who is at present the chief assistant in the electric and lighting department of the St. Pancras Borough Council, has been appointed mains distributor at a salary of £150 a year. Messrs. Harland and Wolff, Limited, have applied for electric current at their lower shipyard, and a sub-committee will deal with the matter at an early date.

Grantham.—Sanction has been obtained to borrow £1,500 for a municipal telephone service. The Postmaster-General has granted an extension of the license and wayleave powers so as to include Buckminster, Sproxton, Knipton, Harston, and Belvoir. Application has been made to the Leicester County Council for the consent requisite under the Telegraph Act, 1892.

Morecambe.—At the last meeting of the District Council the chairman of the Electric Light Committee reported a year's satisfactory progress, and said that had his department been a limited company they would have declared a dividend of 4 per cent. Next year they would do with less money from the rates, although they would have more principal and interest to repay.

Cardiff.—The National Provincial Bank of England are issuing on behalf of the Cardiff Corporation £742,000 3 per cent. stock, the proceeds of which will be devoted to the paying off of temporary advances incurred in respect of the purchase, reconstruction, and electrical equipment of the tramways, the new town hall, the new western sewer, and other purposes. The loan is a trust security, and the price of issue is £96 per cent.

Broughty.—Mr. Forbes Waddell, the gas manager, has been appointed engineer and manager of the Town Council's electricity department, at a salary of £50 for the first year. A special committee is to report anent the disposal of the ground at Dundas-street which was recently under consideration as a site for the electric station. The Council have decided to introduce the electric light into all its premises.

Aldershot.—The electric lighting works at Aldershot were officially opened on Wednesday last by Lady Hildyard, who switched on the light and also started up one of the Willans-Parker steam dynamos. The opening ceremony at the station was followed in the evening by a dinner at the Victoria Hotel. We understand that over 2,000 lamps are already connected to the mains, and that applications for connection continue to come in well.

London Gazette.—The last day for receiving proofs in the estate of G. F. Rogers, electrical engineer, 41, Maxilla-gardens, Notting Hill, London, is May 24. Mr. E. S. Grey, official receiver, Bankruptcy-buildings, Carey-street, W.C. The partnership existing between A. E. Ward and D. Fulton, manufacturing electrical engineers and lighting and power contractors, 4, Browne-street, Bootle, has been dissolved by mutual consent.

Worcester.—The electricity estimates, which came out very well last year, showing a surplus of £1,385, are not so good for the coming year, showing a surplus of £350 only, which is included in the general district rate estimate as a grant towards reduction of the rates. The increased amount payable on the new loans for dividends on stock and contributions to loans fund will account for the reduction in the estimated surplus on the accounts.

Manchester. The Stuart-street generating station will be opened on May 27. Recently some letters appeared in the local Press comparing the electricity charges in Manchester and Salford, much to the disadvantage of the former city. Attention is drawn to the fact that not long ago Manchester raised the price of electricity from 5d. to 5½d. per unit, whilst recently Salford has dropped it from 5d. to 4d., so that consumers are now paying 37½ per cent. more in Manchester than in Salford. The long-distance tramway fares in Manchester are uniformly 2d., while in Salford they are mostly only 1½d.

Stock Exchange.—The Stock Exchange Committee have appointed May 22 as special settling day for the following: Isle of Thanet Electric Tramways and Lighting Company, Limited, 30,000 5 per cent. cumulative preference shares of £5 each fully paid, Nos. 30,001 to 60,000; Cape Electric Tramways, Limited, further issue of 40,000 shares of £1 each fully paid, Nos. 440,001 to 480,000; and have ordered the said securities to be quoted in the official list: Milwaukee Electric Railway and Light Company, 397,000dol. additional 30-year consolidated mortgage 5 per cent. gold coupon bonds, 1926, Nos. 7,604 to 8,000 of 1,000dol. each.

Durham.—The County Council have decided to appoint a special committee to investigate and report upon the following points: (1) how far the county of Durham is covered by electric supply companies working under Acts of Parliament; (2) enquire as to any special facilities existing in the county for generating electricity by waterfalls, etc., and as to the practicability of such facilities being employed to advantage in the county; (3) enquire as to the financial results of electric schemes undertaken by municipal bodies; (4) enquire how far it would be practicable and wise to develop a scheme for an electric supply for the county or through the medium of urban and rural councils consistent with Acts of Parliament already obtained by existing companies; (5) report as to the best mode of procedure fo giving effect to their findings and recommendations.

Lighting Orders.—The Electric Lighting Provisional Orders (No. 4) Bill, confirming provisional orders which have been granted for electric lighting purposes to Amble, Leadgate, and Stanley, has passed the committee stage. The Electric Lighting Provisional Orders (No. 1) Bill, which confirms orders granted by the Board of Trade in respect to the supply of electric power to the local authorities of Wood Green, Edmonton, and Tottenham, has been confirmed. The North Metropolitan Electric Supply Company will not be allowed to come into Willesden except for the purposes of a generating station to supply the North London Electric Railway and districts outside Willesden. The committee also decided to give the local authorities an absolute veto for three years on the entry of the company, after the expiration of which the company might, if a local authority unreasonably withheld facilities from consumers, apply to the Board of Trade to be allowed to supply for power purposes.

National Telephone Co.—At the ninth annual staff dinner of the National Telephone Company, Limited, held last week, Sir H. Fowler, M.P., the president, said there were 1,025 exchanges in Great Britain and Ireland, and the Company's subscribers now numbered 226,000. At the present time there was a telephone for every 183 persons in the United Kingdom. In the year that had just closed they had sent 287 million messages, an increase of 75 millions on the figures of the previous year. The number of telegrams sent through the Post Office was 89 millions, showing a decrease of 838,000 messages. Lord Harris, a director, replied. Mr. W. E. L. Gaine, the general manager, spoke of the competition with the municipality of Glasgow. The Glasgow municipality had started with a system which the Company were leaving off. He thought he would be justified in saying that as the Glasgow Corporation went on and added with their *clientèle* their difficulties would increase, and as they went on this company's difficulties would decrease. This Company had spent money like water in Glasgow, but they were on the eve of having their Glasgow system as perfect and up to date a system as experts could make it. He honestly believed that in the competition with Glasgow, if it was to be a competition of efficiency, the Company would win, and the Corporation of Glasgow would have reason to regret that they had not tried the Company's plan instead of the one they had adopted.

Digitized by Google

Barnsley.—The salaries of Mr. Barker and Mr. Wright, assistants to the borough electrical engineer, have been respectively increased from £130 to £150. Some time ago the Corporation sanctioned the expenditure of £2,000 in increasing the plant, in order to prepare for the incoming tramlines. Since then the engineer has hit on a scheme which, though involving a capital expenditure of £2,600, promises to save something like £500 a year.

Canterbury.—The surveyor, in conjunction with the engineer, has been requested to prepare a specification for painting the public lamp columns, and advertise for tenders for this and for the annual supplies. The surveyor and electrical engineer are also preparing a joint report as to the provision of an inclined way or other means of feeding the destructor, the working of the dust destructor at a lower temperature, and as to machinery for crushing the clinker.

Bolton.—On the proceedings of the Electricity Committee coming before the Council last week, Dr. Panton called attention to the cost of producing electricity in Bolton. Last year they were seventh on the list with a cost of 1·34d. per unit, against ·97d. per unit in Cork. He pointed out that instead of being seventh on the list, Bolton now stood at the top of the list, with a cost of ·96d. per unit. This was the lowest cost ever recorded in the United Kingdom.

Aberdeen Telephones.—The Telephone Committee of the Town Council have met Mr. Bennett, who expressed great satisfaction at the result of the recent canvass, which has given in 700 favourable answers, representing practically 1,000 instruments. Mr. Bennett said he had not the least hesitation in advising the committee to proceed with the scheme. The committee will meet again at an early date to determine what further action should be taken in the matter.

Explosion.—A little mishap occurred with the electric light at Crewe on Saturday evening. A heavy iron lid covering the cable connections was blown into the road, but fortunately no one was injured. The electric light also failed in the neighbourhood, and owing to the lateness of the hour it was impossible for the chief engineer and his staff to rectify matters the same night, but on Sunday the whole of the installations, both public and private, were put into working order.

Ayr.—The electrical engineer (Mr. A. J. Fuller) in his last report states that the whole of the works have run satisfactorily during the last month. The following figures are given: number of consumers as per last report, 520; number connected during month, 17—total, 537. Number of lamps connected as per last report, 22,302; number connected during month, 513—total, 22,815. Units generated as per last report, 643,293; units generated during month, 60,896—total, 704,109.

Swansea.—The Anglo-French Nickel Company have asked for quotations for the supply of electrical motive power to the extent of 130 h.p. to 230 h.p. The application is considered an important one by reason of the possibilities of extending such power to other works, thus providing a day load for the electric lighting station, and the Council have offered the following terms: 1½d. per unit providing a minimum supply of 150,000 units be taken, and 1¼d. per unit if 200,000 be taken.

The Volcano Outbreak.—When the volcano Mont Pelée exploded the fire from it swept the whole of St. Pierre, destroying the town and the shipping, including the steamer "Grappler," a screw steamer of about 900 tons, belonging to the West India and Panama Telegraph Company, which was engaged in repairing the cable near the Guerin factory. The "Pouyer-Quertier" is trying to repair the cable at Point à Petre. She reports that she finds it has sunk 1,200m. where it was formerly only 800m. down.

Sheffield.—The Electric Light Committee propose to reduce their charges for energy for motive power, and have decided that on and after June 26, 1902, the price of electrical energy used for motors be as follows: for all energy used in motors, driving hoists, cranes, passenger lifts, and similar machinery, 2d. per unit; for other motors, 1½d.; to consumers running their motors continuously through the whole of the working hours of each day, 1¼d.; and to consumers whose motors run continuously day and night, 1d.

Luton.—The resident electrical engineer in his last report states that since April 1 3,942 units had been generated; that 218 8-c.p. lamps and one motor of 9 h.p. were being wired, but were not ready for connection; and that the total number of consumers was 59, with an aggregate of 4,556 lamps and four motors of 8 h.p. The resident electrical engineer has been authorised to extend the cables in Park-street West at a cost of £30, and also to report upon the question of reducing the price of current for light and power.

Paddington.—At the last meeting of the Borough Council consideration was resumed of the scheme of the Electric, Gas, and Water Committee for substituting gas for electric light in Westbourne-terrace. The present 14 arc lamps cost £420 per annum, and it was proposed to substitute for them 50 incandescent gas lamps costing £199. 7s. 8d. to instal and £168. 16s. in yearly maintenance, the saving effected by the change being estimated at £253. 14s. annually. Finally, the consideration of the matter was adjourned for six months.

Crewe.—After paying expenses, there remains a profit on the electric light undertaking of upwards of £900 for the year ending March 31, which will be placed to reserve or depreciation account. A sum of £1,300 is to be borrowed for electric lighting purposes, and electric light consumers will be given the option of electing to be charged at the uniform rate of 4½d. per unit or at the present rate of 6d. and 3d. provided that whichever method of charge any consumer selects shall continue in operation for not less than 12 months.

Basingstoke.—The Urban District Council have asked the Board of Trade for an extension of time for their electric lighting order, which expires in June next, in view of the fact that the Council are heavily engaged in arranging new schemes of water supply and sewage, and that if a new sewage system is adopted the present pumping station may be available for the purpose of an electric lighting station. The Board have replied that they will defer consideration of the question of revoking the order for one year from June 25 next.

Rotherham.—The charge for electric lighting for the ensuing year is to be reduced as follows: flat rate of 4½d. per unit, with rebate scale, to be agreed upon. The last report by the engineer, Mr. Edward Cross, on the completion of the first financial year, states that, taking into consideration the small number of consumers connected during the greater portion of the period the works had been in operation, the amount sold was fully satisfactory. There is a small profit on the year, but it had been generally anticipated that there would be a loss.

Hartlepool.—At the last quarterly meeting of the Town Council a lengthy discussion took place on the draft license and agreement for the proposed municipal telephone undertaking being submitted for approval. Ultimately the matter was referred back. A letter from the Northern Counties Electric Supply Company relating to the terms for public and private lighting, equipment, and power has been deferred for further information, and application has been made to the West Hartlepool Corporation for terms for the supply of electric energy and fittings for public and private consumers.

Darwen.—The result of the last year's working of the electricity department shows a profit of £126. The production, which in the year ended March 31, 1901, was 266,000 units, reached during the past year 546,000 units—more than double. A great part of the power thus generated had been utilised for traction. There had been about 30 per cent. increase of current for lighting, about 10 per cent. increase in street lamps, and 2½ times increase in the current used for traction. The average selling price for the year ended March 31, 1901, was 2¾d. per unit. Last year it was 2·418d., a reduction of over ¼d.

Lowestoft.—Sanction has been obtained to the loan of £7,143, which the Council applied for recently for a new 500-kw. set and condensing plant. All places of worship are to be supplied with current at a fixed rate of 6d. per Board of Trade unit, and a cable is to be laid from the Grand Hotel to the new Congregational Church at a cost of £45. The resident electrical engineer (Mr. Bruce) in his last report states that there are now 11,495 8-c.p. lamps connected to the mains, representing 243 consumers, thus giving a total of 310 extra 8-c.p. lamps for the month. Applications for about 1,100 lights have been received.

Ealing.—The annual report of the electric lighting department of the Town Council contains the following very satisfactory paragraph: "A profit and loss account and balance-sheet of the undertaking has been prepared for the year ending March 31, 1902, and shows that the department has at least reached the profit-earning stage, and after meeting all charges, both for working expenses and interest and principal repayments, has made a profit of £420. 10s. 11d." Mr. Knight, the engineer, and Mr. Lewis, the business manager, are both to be congratulated for it—a fact which was well recognised at the last Council meeting.

Emden-Vigo Cable.—The working of the German Marine Telegraph Company's Emden-Vigo cable suffered many interruptions during the past year. The first fault arose on Jan. 28 and continued until March 13, while the second interruption was of shorter duration, having extended from Nov. 1 to the 9th of the same month. The repair of the cable at the first break occupied a considerable time in consequence of the unfavourable weather, and greatly increased the expenditure. The net profits for 1901 amount to £6,189, as compared with £12,058 in the previous year, and the dividend declared is at the rate of 3 per cent. as against 5 per cent. for 1900.

Pacific Cable.—The Prime Minister of the Australian Commonwealth has been advised by the Pacific Cable Board that it is proposed to pay off the loan money required for the cable—which will carry interest at the rate of 3 per cent.—in terminable annuities spread over 50 years. Great Britain, which finances the scheme, is responsible for five-eighteenths of the cost—estimated at £2,500,000—and Canada, Queensland, and New South Wales are responsible for the balance. In the event of the receipts not being sufficient to meet the working expenses and interest, the contracting countries will have to make good the deficiency in proportion to their obligation.

Tonbridge.—The Electric Lighting Committee of the Urban District Council have re-elected Mr. Race as their chairman for the ensuing year. Twelve further applications for the supply of electricity have been received. The contractors are proceeding satisfactorily, nearly one-half of the whole of the trenching has been done, the boilers have been completed, and the pipework is about to be commenced. The committee have asked Mr. Hammond to prepare a specification and obtain tenders for the purpose of wiring the electricity works. The work of providing a supply of electricity in the Dfive and Yardley-park will be proceeded with in due course.

Electric Launch Stations.—The Thames Valley Launch Company, Limited, Weybridge, Surrey, have already branch works and charging stations for electric launches and cars at Maidenhead, Hurley, Henley, Pangbourne, and Shillingford Bridge, and they will shortly open two new stations, one at Windsor and one at Reading. The ordinary price charged for current is 1s. 6d. per unit, but to purchasers of their own boats the company, besides allowing the free use of their stations for storage purposes, reduce this charge to 8d. per unit, which makes the cost of running the smaller size boats approximately 2d. per mile. We notice that the company have now a large number of specially-fitted electric launches for hire.

Burnley.—The electrical engineer has been asked by the Electricity Committee for instructions as to the charges to be made against the Tramways Committee for the supply of electrical energy for traction purposes. The committee, after carefully considering the matter, resolved that the electrical engineer send in an account for the energy used at the rate of 1⅞d. per unit for energy supplied within the

Digitized by Google

borough, and 2d. per unit for energy supplied in Padiham and Reedley Hallows, he estimating the energy used within and without the borough as equitably as he could. When the matter came before the last meeting of the Council it was moved to take back that minute for further consideration. A portion of each committee is to meet to discuss this and other matters.

Kensington.—The Works Committee are about to purchase seven electric arc lamps and columns for Kensington High-street, between Wright's-lane and Earl's Court-road, at £171. 10s. Notices and plans received from the undermentioned electric lighting companies relative to proposed extensions of their mains in the borough have been agreed to—viz.: Kensington and Knightsbridge Electric Lighting Company—Young-street, Ball-street, King-street, and Burden-mews; Notting Hill Electric Lighting Company—Ladbroke-road and Bedford-gardens; and Brompton and Kensington Electricity Supply Company—Cromwell-road. Amongst the conditions we note a very sensible one, which we trust will soon become universal—namely, that the proposed main in Ball-street be laid at the same time as the Post Office telephone pipe, sanction for which has recently been given by the Council.

Cable Ship.—The steamship "Colonia," recently completed by Messrs. Wigham, Richardson, and Co., of Low Walker-on-Tyne, has been handed over to her owners—the Telegraph Construction and Maintenance Company—after a successful trial trip off the Tyne. The *Eastern Morning News* says the "Colonia" has the reputation of being the largest cable ship afloat, and she is a pretty model to boot, which is more than can be said for some of the older cable ships. In her four cable tanks she can stow 4,000 miles of deep-sea cable, and her equipment includes very complete installations of dynamometers and other plant necessary for the work of cable laying. After receiving her stock of cables she will at once proceed to the Pacific to complete the all-British cable round the earth between Vancouver and Fanning Island, thereby joining the cable laid *via* Fiji and New Zealand to Brisbane.

Huddersfield.—A further meeting of business men has been held at the offices of Messrs. Armitage and Norton, chartered accountants, Huddersfield, at which additional information as to the scope of the proposed electricity undertaking was given. Mr. Witting and Mr. Kolben were introduced to the meeting, and gave their reasons for the belief in the success of a business of the nature already described by us if it were set up at Huddersfield. Several questions were asked and answered, and Mr. Witting intimated that his firm would be prepared to put £20,000 into the concern. A sub-committee was formed to further interview Messrs. Witting and Mr. Kolben, with the object of getting all the necessary information to lay before a public meeting of the townspeople. The following is the committee: the Mayor, Alderman J. A. Brooke, Mr. John Sykes (Lindley), Mr. W. H. Armitage, and Mr. E. Crowther, with power to add to their number.

Fulham.—We understand that the Council on Wednesday rescinded the following resolution of the late Vestry: "We have adopted the following report from our Permanent Sub-Committee—viz.: We beg to report that we have had submitted to us information obtained by the clerk and consulting engineer from the various electric light undertakings in the Metropolis, and after full and careful consideration we recommend . . . and that 2½d. per unit be the charge for current for power or heating purposes." And adopted the following charges for energy supplied for motive power: to all consumers having motors installed of a power up to and including 25 b.h.p., 2½d. per unit; to all consumers having motors installed up to and including 50 b.h.p., 2d. per unit; and to all consumers having motors installed of over 50 b.h.p., 1½d. per unit, the brake horse-powers being the aggregated rated powers of the motors.

Limerick.—The minutes of the Electric Lighting Committee presented to the Corporation at their last meeting contained the following recommendations: "That the appointment of Mr. Baker, C.E., gas engineer, as assistant engineer and clerk of works, in connection with the generating station and the foundations, be recommended. That the Council pass the financial control of the electrical works to the care and management of the Gas Committee of the Borough Council. That a committee of five members be appointed who should meet regularly and deal with Mr. Enright and Mr. Baker on all points that may arise during the progress of the works, and who will act as superintendents, and visit the works periodically and report to Council on all matters in connection with the undertaking and the lighting of the city generally." As there appeared to be a legal difficulty as to whether they could give the control of the finances to the Gas Committee as at present constituted, it was decided to adjourn the further consideration of this point until legal advice had been obtained.

Bristol.—The water-softening plant (which has not been enlarged since the initial installation in 1893) is now inadequate for the demands made upon it. The electrical engineer has prepared a scheme for the erection of additional plant capable of softening 8,000 gallons per hour, and for the provision and erection of additional feed-water filters, feed and general service pumps, which, with the plant already laid down, will meet all demands likely to arise from the present works, at an estimated cost of £2,915. Plans are being prepared for extension of Avonbank works in consequence of the rapid growth of the undertaking. The Sanitary Committee have passed the following resolution: "That the gas company be requested to state, having regard to the extension of the electric lighting which the Council have determined to carry out, the price per lamp per annum at which they are prepared to supply gas to the public gas lamps, including maintenance and repair, it being understood that the Council will not bind themselves not to still further extend public electric lighting."

Dutch-German Cable.—The report of the committee of the Second Chamber of the Dutch States-General on the convention between Holland and Germany regarding telegraph cables to the Dutch East Indies shows that some members of the committee consider that the Government places too high an estimate on Dutch interest in the proposed new cable communication. The majority, however, is convinced of the importance of the scheme, especially in time of war or when there is danger of war, but several of the members are opposed to the means by which it is proposed to carry out the project. They ask why it is necessary to co-operate with Germany, a course which would mean the payment of a considerable subsidy for 20 years, and would impose dangerous obligations in Holland, while at the same time entailing the danger of a preponderance of German influence in the subsidised company. These members suggest that a cable between Menado and the Philippines, or, better still, a cable between Batavia and the Philippines, might be preferable. It is also pointed out, however, that the interest of Germany and of the United States of America in the proposed cable would guarantee the safety of communication in time of war.—*The Times.*

Presentations.—At a smoking concert at Middlesbrough last week the staff of Middlesbrough Corporation electricity department presented Mr. Harold W. Clayden, the late borough electrical engineer, with a handsome chiming travelling clock on the occasion of his marriage and leaving to take up a new appointment in South Africa. The presentation was made by Mr. W. Telford, the chief assistant engineer, on behalf of the staff, and Mr. Clayden, in responding, thanked the staff for their kindness shown to him during his residence in Middlesbrough and for the assistance they had given him in placing the electricity undertaking in its present prosperous position. Several other toasts were given during the evening, Councillor Main responding on behalf of the Electricity Committee. On Friday evening, the 9th inst., the engineering staff and employés of the Manchester Corporation electricity works held a convivial gathering at the Albion Hotel, Manchester, the principal item being the presentation to Mr. W. F. Long with a token of their esteem, in the shape of a handsome dressing case, prior to his leaving to take up the important position of chief electrical engineer to the Corporation of Capetown. The presentation was made by Mr. S. L. Pearce, the deputy chief engineer, who, in a few well-chosen words, alluded to Mr. Long's good work in Manchester during his six years' stay, and expressed the sincere regret of the staff in now having to wish him good-bye.

Coronation Illuminations.—Albemarle-street is to be decorated and illuminated in a very novel manner, real and artificial flowers, in combination with electric lighting, having been chosen by Messrs. Defries and Sons for the approved design. On Tuesday the General Purposes Committee of the London County Council reported with regard to the Coronation that the Embankment would lend itself to a very effective scheme of illumination. Reference was also made to the proposal of art students, already described, to decorate Westminster Bridge. Including the cost of this scheme (£500), the committee proposed to spend £3,500, and on the motion of Lord Monkswell the necessary power was given them. The Electric Lighting Committee of Edinburgh Town Council have agreed that electric current for the purpose of illuminations on the occasion of the Coronation rejoicings should be provided at 2½d. per unit, on conditions to be arranged by the electrical engineer. In Barnsley, electric light is to be supplied free of charge for the purpose of the illumination of the Harvey Institute, the town hall, the municipal buildings, and the corn exchange, on the occasion of the celebration of the King's Coronation. The following are the conditions as to the free supply of electricity for the purpose of illumination at the Coronation at Morley: (*a*) the supply to be given to then present consumers; (*b*) the supply to be given on June 26, 27, and 28 from 10 to 12 p.m.; (*c*) the connections and all work to be done at the consumer's expense and to the satisfaction of the engineer. The Brighton Corporation have resolved to spend £1,500 towards Coronation decorations and illumination; the County Council £50. Hove will also contribute an amount.

Salisbury.—Acting upon the advice of Messrs. Frankland, Phillips, and Co., of Poplar, the dean and chapter have decided to place a new and efficient system of lightning conductors on the cathedral. The present conductor attached to the spire will be replaced by a copper band. Additional conductors will be fixed on the western turrets, and it is also proposed to place points on the east and the transept gables, the lead covering the roof of the cathedral forming a connecting link between the whole of them. The building will thus be afforded the greatest possible protection against injury by lightning. The cost of the work, which will probably be commenced soon after Whitsuntide, is estimated at £300. It may be remembered that at the December meeting of the Town Council a resolution was passed by which the Salisbury Electric Light and Supply Company, Limited, were allowed to temporarily erect and light two specimen arc lamps in the city. The gas company obtained a similar privilege. Each company has now taken advantage of the permission thus conferred, and has put up two lamps in the Market-place. The electric light company's lamps are of 1,500 c.p. each, and two side lights of 25 c.p. each are attached to the same poles. The side lights are used after 11.30 p.m. The company has also erected a specimen 32-c.p. lamp for incandescent lighting. Tenders for public lighting will be submitted by both companies for consideration by the Town Council at their June meeting. To meet the great growth of telegraph traffic in the Salisbury district, a new wire fitted with improved "duplex" apparatus has just been completed from Salisbury to London, at a cost of upwards of £1,300, making in all eight complete telegraph circuits, which are capable of being enlarged to a total of 12 circuits available for the direct transmission of public telegrams passing between this city and the Metropolis.

Cleckheaton.—Substantial progress has been made in regard to the combined electric generating station and refuse destructors which the Urban District Council have in hand in accordance with plans and specifications prepared by Messrs. Baker and Appleby, the consulting engineers, and Mr. Lund, the Council's surveyor. The works, approached from the Dewsbury road, are situated on a plot of land near the existing gasworks at the south-eastern end of the town in

Digitized by Google

close proximity to the Syke Beck, along which many of the other important works of the district are located, and from which the necessary water supply is taken. The chimney shaft, 129ft. high and 9ft. diameter, is completed, and is now a prominent landmark visible from either of the existing railways. The buildings, constituting boiler, engine, and accumulator rooms, with office for the staff, are roofed in. The water-tank is erected and ready for use, whilst the economiser, accumulators, and overhead traveller are delivered and now in course of erection. Two of the steam dynamo sets (Belliss-Morcom-Johnson-Lundell) are ready for testing, and it is expected that the third set will be also ready before the end of the present month. The switchboard is mounted at Messrs. Dorman and Smith's works, where they are busily engaged in putting together the whole of the component parts prior to dispatch the first week in June. The boilers, condensers, pumps, and steam-piping in like manner are well in hand, so that by the end of June there is every probability that the whole of the machinery and accessories will be at the generating station, where, we are assured, no time will be lost in making the various connections between the separate portions to have them in working order. Outside the station the feeders and distributing cables are now being laid in the main streets, and as the Council hope to supply energy to the tramway company for the cars running through the district, as well as for lighting and power purposes in the town, the prospects are extremely encouraging, a comparatively large return being secured from the commencement. It is anticipated that the works will be opened in September next.

PROVISIONAL PATENTS, 1902.

MAY 5.

10269. Improvements in electric arc lamps. Veritys, Limited, and William Reginald Ridings, 11, Burlington-chambers, New-street, Birmingham.

10271. Improvements in apparatus for automatically supplying electric power to operate mechanism in clocks and other instruments or machines. Herbert Scott, 6, Selborne-terrace, Bradford.

10302. A portable apparatus capable of being concealed by a doormat or other covering which completes a circuit of electricity when trodden on. Jesse Landon, 134, Queen's-road, Watford.

10309. Improvements in or relating to plate, die, printing, and metal presses by electric-kinetic power. Frank Charles Frederick Knaak, 65, Imperial-buildings, Ludgate-circus, London.

10329. Improvements in secondary batteries. Eugène Lespagnol, 53, Chancery-lane, London.

10335. Improvements in dynamo-electric machinery. Albert Henry Midgley, Norfolk House, Norfolk-street, Strand, London.

10342. Improvements in armature windings and in the method of producing same. Thomas Joseph Murphy, 55, Chancery-lane, London. (Complete specification.)

10357. An electric tinder-box. Manuel Simonet Lombardo, 40, Chancery-lane, London.

MAY 6.

10369. Improved electric light switch. John Crawford Macalester, Box 23, Athenæum, Glasgow.

10357. An improved adjustable trolley for electric tramcars and the like. John Reynolds, 3, Berkeley-place, North-road, Plymouth.

10444. Improvements relating to electric measuring instruments. Carl Beez, 27, Chancery-lane, London.

10452. Improvements in wireless telegraphy and means therefor. John Edward Evans-Jackson, 19, Holborn-viaduct, London. (De Forest Wireless Telegraph Company, United States.) (Complete specification.)

10457. Improvements in storage batteries. Jerome Redding, Llewellyn Day Lothrop, and Isaac William Deering, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

10459. Improvements in controllers for electric motors. Herbert John Haddan, 18, Buckingham-street, London. (David Bergman, Sweden.)

10460. Improvements in trolley collectors for electric traction systems. Thomas Joseph Murphy, 55, Chancery-lane, London.

MAY 7.

10466. Electrical appliance for working pile drivers. James Garvie, 69, Victoria-street, Westminster, London.

10473. An improved glass globe for use with electric glow lamps. George Davis, 34, Victoria-street, London.

10512. An improved electric conduit. George William Jones, 4, Bishopsgate-street Within, London.

10529. Improvements in or relating to overhead electric trolley traction systems. James Watson, 111, Hatton-garden, London.

10532. Improvements in portable, secondary, or other electric batteries, accumulator plates, and the like. Lars Bristol, 33 Cannon-street, London. (Complete specification.)

10533. Improvements relating to electric jacquard card punching and similar machines. Oscar Zerkowitz, 27, Chancery-lane, London.

10534. Improvements in Rontgen tubes. Friedrich Dessauer, 6, Lord-street, Liverpool.

10538. Improvements in or connected with trolleys for use with overhead conductors in electric traction. Carl Stoll, 70, Chancery-lane, London. (Complete specification.)

10541. Improvements in and relating to electric clocks and the like. William Edgar Palmer, Palace-chambers, Westminster, London. (Complete specification.)

10546. Improvements in or connected with electric conductors, and attaching devices for lamps or other current takers. James Grieve Lorrain, Norfolk House, Norfolk-street, Strand, London. (Hector Alan Macdonald, France.)

MAY 8.

10581. Improvements in electric lamps of the Nernst type. William Richard Wynne, 3, New-court, Lincoln's-inn, London.

10590. Improvements in incandescent electric lamps. George Sweetser, 11, Southampton-buildings, Chancery-lane, London.

10594. Cleats for fastening electric wires or cables in casing or other carrying arrangement temporary or otherwise, or for permanent fixing to walls, ceilings, roofs, and the like. Victor Watson Riley and Herbert William Rowing, 1, St. George-street, London. (Complete specification.)

MAY 9.

10695. Improvements in or connected with attaching metallic connections to the plates of electric batteries. John Crisp Fuller, George Fuller, and Dyson Fuller, 33, Chancery-lane, London.

10701. Improvements in incandescent electric lamp fittings. Arthur Albert Guest, 128, Colmore-row, Birmingham.

10710. Improved switchboard for effecting telephonic intercommunication. John Young, 21, Gloucester-walk, Campden Hill, Kensington, London.

10733. Improvements in automatic electric regulating or controlling devices or systems. Wilhelm Stockmeyer, 18, Buckingham-street, Strand, London.

MAY 10.

10755. Improvements in electrical switches. John Henry Tucker, Sampson-road North, Birmingham.

10758. The speedy trolley wire catcher for electric tramway cars. Alfred Ernest Bailey, 51, Salisbury-road, Plymouth.

10788. Improvements in or in connection with wireless telegraphy for signalling between stations either fixed or moving. Charles Ernest Wisner, 6, Lord-street, Liverpool.

10800. Improvements in electrostatic instruments. Sebastian Ziana de Ferranti, 18, Southampton-buildings, Chancery-lane, London.

10811. Rotary carbons for electric arc lamps. Albert Ernest Carter, 64, Church-street, Brighton.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published May 29.

1901.

9770. Electrical sparking devices for firing the charges in internal-combustion engines and for similar purposes. Brown.

9781. Insulator for use with bracket suspensions of overhead trolley systems and the like. Quin and Smith.

10869. Manufacture of incandescence bodies for electric lighting. Abel. (Siemens und Halske Aktiengesellschaft.)

11003. Apparatus for transmitting and receiving electric signals or for firing explosive mines. Blochmann and Bichel.

11584. Lightning conductors. Hedges.

12552. Electric arc lamps. Crompton and Co., Limited, Hodgson, and Ewart.

12739. Driving of centrifugal and other machines by means of electric motors. Pott and Williamson.

12835. Electric cranes and other electric lifting appliances. Stothert and Pitt, Limited, and Stothert.

13732. Method of and apparatus for effecting electric traction on tramways. Abel. (La Soc. Anon. pour la Transmission de la Force par L'Electricité.)

15833. Armatures for electric clocks. Wise. (Actiengesellschaft "Magneta," Electrische Uhren ohme Batterie und ohme Contacte.)

21942. Process for the electrolytic treatment of tin and apparatus therefor. Nauhardt.

1902.

1888. Systems of electrical distribution. Hopkinson.

3224. Intercommunication telephone systems. Cerebotani and Baumer.

4520. Electric batteries. Apple.

7361. Method of connecting continuous-current motors to the supply network on starting. Siemens Bros. and Co., Limited. (Siemens und Halske Aktiengesellschaft.)

Supplement to "The Electrical Engineer,"

MAY 16, 1902.

CARDIFF ELECTRICAL TRAMWAYS.

May 1, 1902, will be recorded as an eventful day in the history of Cardiff, for on that day the town inaugurated its new system of electrical tramways with considerable pomp and ceremony. In delightful weather 12 gaily-decked cars conveyed the guests of the Corporation in procession over the various routes to be inaugurated, and incidentally provided a test on the trolley sections severer, perhaps, than they will ever be called upon to withstand in ordinary working. It speaks well for the design and quality of the materials employed that no hitch of any kind occurred, especially when the incomplete state which was revealed at the power station is considered. However, it is not our intention to dwell upon the morning's proceedings, nor upon the luncheon given by the Mayor which followed, but rather to devote our space to the practical side. In doing this we have considerable pleasure, since the plant installed is undoubtedly one of the best which has come to our notice for some time past. Both in the power station and outside there is evidence of originality in design which is refreshing, and at once proves the capacity of the Corporation engineers. Hitherto the experience of Cardiff in electrical matters has not been of a too prosperous nature, but the new enterprise upon which the Corporation have embarked should tell another tale. In a town bustling with energy like Cardiff, the time-saving advantages offered by the electric car service are bound to be appreciated. The new power station is destined, however, not only to supply current for traction purposes, but also for general power and lighting purposes. A separate network of mains is in hand for this purpose. A sub-station will, we understand, be constructed on the site of the fish market, from which the docks will be supplied with electrical energy in bulk. The applications from this source of demand already represent the promising aggregate of some 1,000 h.p. It will be some time, however, before the whole scheme is complete: hence we shall confine ourselves in the following to a description of the tramways portion The site of the new power and lighting station is at the opposite end of the town to that of the old lighting station. The latter, which contains an alternating-current plant, will be retained for supplying the outlying districts. It is noteworthy that the Corporation's own engineers have been responsible for the design of the new scheme throughout. Mr. Arthur Ellis,* upon whom the responsibility for the design of the whole of the electrical equipment devolves, has, it should be mentioned, been ably assisted by Mr. T. T. Davies. There is one blemish in the tramways—namely, in the centre of the town—where, owing to a very narrow stretch of street, the track has to make a wide detour. Some seven years hence the leases of the property in this street expire, when the opportunity will, perhaps, be taken of remedying the defect. We have so often referred to the enterprise of the Cardiff municipality that it is unnecessary to labour the more recent proof of that enterprise—the electric tramways. Fortunately, Cardiff has in Mr. Harpur (the borough engineer) and Mr. Ellis (the electrical engineer) two gentlemen of great ability and experience, and to the combined efforts of these gentlemen the successful inauguration of the tramways system is due. Our description of the system is so lengthy and complete in most of the details that no object would be served in a longer introduction. We wish the latest work of the municipality all success.

COUNCILLOR T. ANDREWS, CHAIRMAN TRAMWAYS COMMITTEE, CARDIFF.

COUNCILLOR F. J. BEAVAN, THE MAYOR, CARDIFF.

MR. WILLIAM HARPUR, BOROUGH ENGINEER, CARDIFF.

Historical.

In 1898 the Corporation obtained parliamentary powers to construct about 15 miles of tramways and also to purchase and alter the Cardiff Tramway Company's lines, Mr. W. Harpur, M.I.C.E., the borough engineer, being the engineer for the scheme. The Corporation on Dec. 11, 1899, decided to construct the track work by their own

* **Arthur Ellis, M.I.E.E.**, the electrical engineer, served his apprenticeship with Messrs. C. A. Parsons and Co., Newcastle-on-Tyne, after which he took a position with the Newcastle and District Electric Light Company in order to secure a practical training in electric light station work. In August, 1892, he left this company to join the Cambridge Electric Supply Company as resident engineer during construction, under the chief engineer. Shortly after the completion of this plant he took over the duties of chief engineer, and held this office until October, 1893, when he left the company to act as outside manager for Messrs. C. A. Parsons and Co. In April, 1894, he was appointed to the post of borough electrical engineer to the Corporation of Southport, and in April, 1896, he was appointed to Bolton, and in October, 1899, was appointed general manager of the tramways. In June, 1900, he was the successful candidate for a similar position at Cardiff. In December, 1900, he was appointed engineer and manager of the electric lighting department, in which capacity he has since acted, in addition to designing and carrying out the complete scheme of tramways herewith described.

Digitized by Google

workmen, and entrusted Mr. Harpur with the carrying out of the work in question. The work was commenced in Cathedral-road on Dec. 18, 1900, with the object of getting the line in that road open in time to accommodate the traffic to the Royal Agricultural Show on June 26, 1901, and this was successfully done, the line being provisionally passed by Major Druitt, R.E., the inspector appointed by the Board of Trade, on June 18, 1901. In the meantime, Mr. Arthur Ellis, M.I.E.E., was appointed to design and carry out a complete scheme of electrical tramways for the town, involving an expenditure of £300,000, and the borough engineer received further instructions to proceed with the remainder of the above-mentioned route to its terminus near the Clarence-road railway station at the docks, and also with the branches therefrom along Wood-street and Neville-street, and likewise with the construction of a tramway along Castle-road, Albany-road, etc., to the end of Ninian-road at Roath Park; the whole of these tramways, with the exception of that along Neville-street, being provisionally approved for horse traction on Jan. 3, 1902. On Dec. 12, 1901, after long and protracted negotiations with the Cardiff Tramway Company, terms were arranged whereby the tramway company agreed to hand over their lines to the Corporation at 12 p.m. on Dec. 31, 1901. The borough engineer had in the meantime prepared plans for the reconstruction of the old tramways, which reconstruction, reduced to single line, represented a mileage of about 12 miles of single track. The Corporation asked the borough engineer to name a time in which he would undertake to get this length of line reconstructed, and he undertook to do so in six months—*i.e.*, by June 30 next—and up to the present time 11½ miles have been completed, and this, together with the new lines mentioned above, makes a total length of 20 miles of finished track.

The reconstruction of these tramways has, of course, necessitated a lot of special work in the way of junctions and crossings, etc., on the track work, and also of various street alterations, notably the lowering of the roadway under the Bute-street bridge, which compelled extensive alterations to the sewers under the said bridge, and also pumping arrangements to keep the surface of the road under the bridge clear of water, and this difficulty is being met by electrically-driven centrifugal pumps, which are being placed under the roadway at that point. The pumps are in duplicate, and are being supplied by Mr. Napier Prentice, of Stowmarket, Suffolk. They are arranged to start automatically directly the water commences to rise in the pump well. The following is a detailed description of the undertaking.

Buildings.

The tramway power station is situate on the northern side of the Newport-road at the extreme end of the Roath route (see Fig. 1), and is a plain but substantial red-brick building, treated with pleasing architectural effect. An exterior view of the station is given in Fig. 2. Entering the buildings at the principal entrance, which is at the further end from Newport-road, we pass through a spacious hall and enquiry room, to the right and left of which are placed the men's messrooms and storerooms, smiths' shops, general repair shops, etc., while on the first floor are the engineer's offices and rooms. A few yards from the entrance hall we enter the engine-room, which is 104ft. long, 60ft. wide, and 56ft. high, is cool and well ventilated, and is lined throughout with cream glazed bricks. At intervals along the side walls are built substantial piers, with semi-circular arches, carrying the travelling rails of the 10-ton gantry crane, which runs the whole length of the room. At the side of the engine-room is the boiler-house, which is the same length as the former—56ft. wide and 48ft. high—

Digitized by Google

while beyond the boiler-house are placed the coal bunkers, into which the coal trucks will be brought direct from the Taff Vale Railway (Roath branch). The roofs throughout are supported by mild-steel principals and framing of neat design, composed of angles and flat tiebars. It should be mentioned that the building has been erected by Messrs. W. Symonds and Co., Cardiff, at a contract price of £16,100; Messrs. A. D. Dawnay and Sons, of London and Cardiff, being the contractors for the steelwork. The octagonal chimney stack, also of red-brick construction, is 160ft. high, and is surmounted by a heavy granite capping, each of the eight stones of which weigh nearly 1½ tons. The hoisting and fixing of these stones at such a height was a matter of considerable difficulty. The stack was erected by Messrs. Clark and Co., of Cardiff, at a contract price of £1,563, while Mr. W. Irwin acted as clerk of works for the whole of the buildings. It is intended at an early date to duplicate the boiler-house and coal bunkers on the opposite side of the engine-room, and the whole of the buildings are finished with a temporary end with a view to further extension towards Newport-road as the necessity for the same arises.

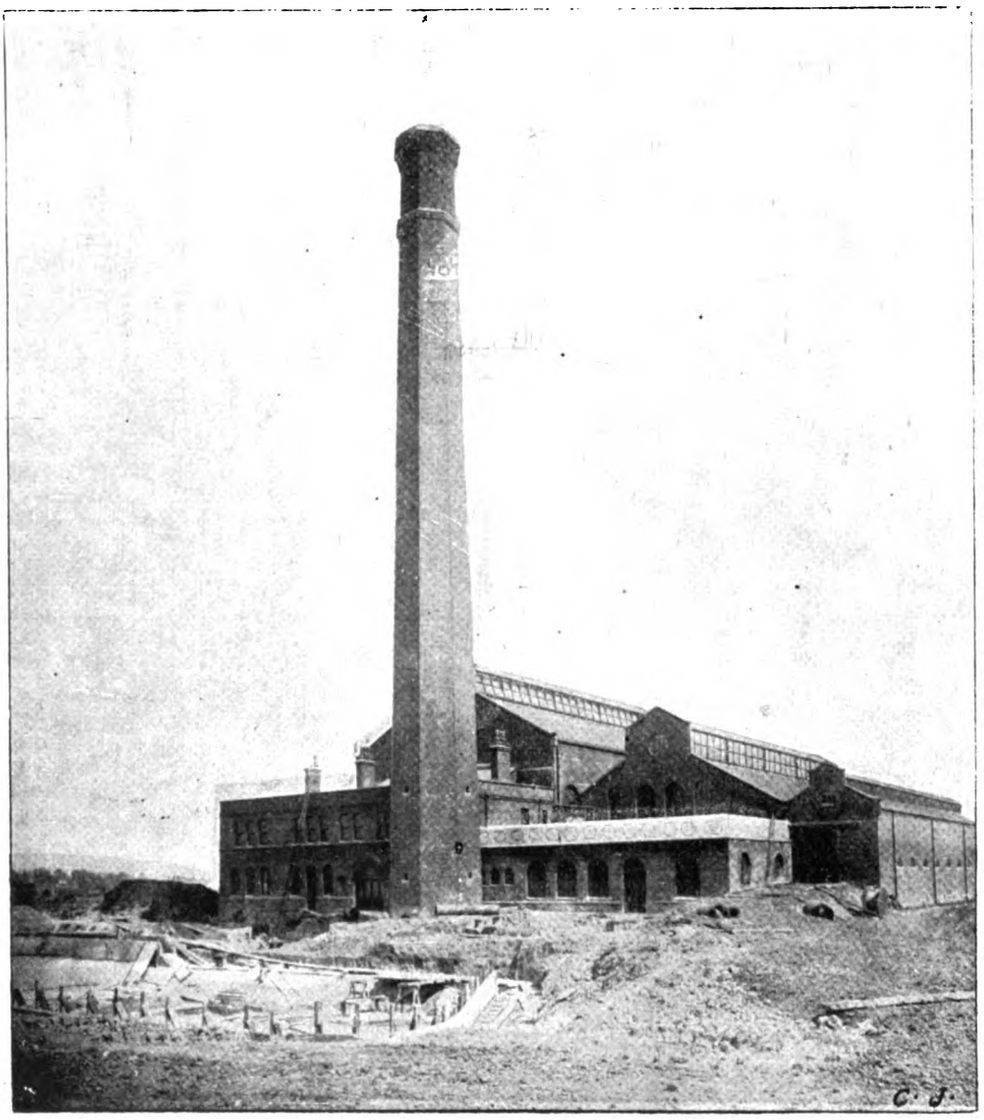

Fig. 2.—Exterior View of Tramways Power Station, Cardiff.

Close to the power station and facing the Newport-road is situated the Roath car depôt, a spacious building consisting of a car-shed, 320ft. by 136ft.; machine shop, 120ft. by 66ft.; painting shop, 90ft. by 33ft.; smithy, 29ft. by 25ft.; carpenters' shop, 29ft. by 25ft.; messroom and kitchen, suite of offices, cloakroom, and large store columns. It is also equipped with a complete sand drier, wet and dry sand stores, etc. The arrangement of the various shops, etc., beyond the car-shed proper is shown in the plan (Fig. 3). An island office provided with glass panels, and situated as shown, enables the foreman in charge to keep an eye on the staff. The rails in the car-shed are carried on cast-iron columns, thus forming a pit 4ft. deep under the cars for the purpose of inspection of motors, etc. At the top end of the shed an electric traverser is arranged, so that a car can be transferred from one track to any other without leaving the car-shed. There are four tracks leading in and out of the shed, the facilities provided for the rapid handling of the cars being therefore admirable. In the machine shop there are two travelling gantry cranes, each 32ft. span, and capable of lifting a complete car body. The buildings are built in red pressed brickwork with red Wilderness, Forest of Dean stone dressings, the main car entrances being fitted with Kinnear's patent rolling doors. When complete the car-shed will be capable of accommodating 70 cars. The buildings are being erected by Mr. D. W. Davies, of Cardiff, at a contract price of £21,988; Messrs. A. D. Dawnay and Sons being sub-contractors for the steelwork, and Mr. Irwin acting as clerk of works. A longitudinal section, front elevation and section, and details of the roof principals and steelwork of the Roath car depôt are shown respectively in Figs. 4, 5, 6, and 7. The glazing on the car-shed will be on the patent "Eclipse" system, supplied by Messrs. Mellowes and Co., of Corporation-street, Sheffield, and London. The principle of this system of glazing is shown in Fig. 8. Another car depôt is situated at Clare-road. This is of similar construction to the above, though somewhat smaller. It provides accommodation for 27 cars, and is replete with workshops, offices, and messrooms, etc. This depôt was built and completed last year by Mr. D. W. Davies (the contractor for the Roath car depôt), Mr. T. Williams superintending its erection. The whole of the buildings, including the

Digitized by Google

structural steel and iron work, were designed by Mr. Wm. Harpur, M.I.C.E., the borough engineer. Their design throughout bears evidence of the great care which has been bestowed by Mr. Harpur on details conducive to the efficiency of the buildings as a whole. Among other things, we noticed when inspecting the buildings recently that the question of ventilation had received special attention. In the power station, for instance, vertical roof windows are provided, which can be opened simultaneously along the whole length of the engine-room from the switch-board gallery, while the end walls are also furnished with ventilating windows. The general appearance of the engine-room is, moreover, particularly fine, the proportions being generous and the finish uncommonly effective.

Boiler-House Equipment.

Steam Generating Plant.—In the boiler-house there are at present installed four boilers, but the extensions now in hand provide for a further six. The boilers are of the Lancashire two-flue type by Messrs. John Musgrave and Sons, Limited, Globe Ironworks, Bolton, and are fitted with mechanical stokers. Each boiler is 30ft. long by 8ft. diameter, and designed for a working pressure of 160lb. per square inch. The fittings throughout are by Messrs. J. Hopkinson and Co., Limited, Huddersfield. A superheater is provided at the back end of each boiler. These were also supplied by Messrs John Musgrave and Sons, Limited, and are arranged so that they can be easily raised and withdrawn from the flue after being disconnected from the steam-pipes. An economiser by Messrs. E. Green and Son, Limited, Manchester, combining the latest improvements, is erected in the main flue of the boilers. The scrapers of this economiser are driven by an electric motor in the usual manner.

Mechanical Stokers and Coaling Arrangements.—The boilers are fired by means of Vicars's patent self-stoking smokeless furnaces. In these machines the fuel is first pushed on to dead plates by reciprocating rams or plungers, and then on to the moving fire-bars, which gradually take the mass further into the furnace and ultimately discharge same on to bottom of flue, where combustion is completed, and the clinker and ash periodically removed. The action of the furnace necessitates the volatile hydrocarbons passing over the incandescent coke, thereby insuring smokelessness. The grates are proportioned so that no difficulty is experienced in maintaining 14 per cent. carbon dioxide in the products of combustion leaving the furnace, without any carbon monoxide. The driving gear for each furnace is entirely separate, also for the coal feed and bar motions, and the stroke on the latter is variable. The hoppers are divided in the centre so that gauge glasses can be brought to the front. Coal is fed into the hoppers of the stokers from an overhead steel bunker having an inclined base, and which is fitted with dampers or sluices for regulating the supply of fuel to the hoppers. These dampers are opened and closed by means of a screw actuated by the fireman through chain wheels. The bottom of the bunker is made of $\frac{5}{16}$in. plate stiffened with 5 by 3 H girders; the vertical side of $\frac{1}{4}$in. plate stiffened with 4in. by 3in. tees, and the top of $\frac{1}{8}$in. plate stiffened with 3in. by 3in. tees. The bunker is designed to hold about 250 tons of fuel, and is supported by 18in. by 7in. girders built in wall at one end, and by strong cast-iron columns at the other end. The fuel is brought direct into coal-store by railway wagons, and can be discharged either into the bunker or into the reserve coal-store, which latter extends the full length of the boiler-house under the railway lines,

openings being provided opposite each boiler, so that fuel can be easily withdrawn when required. A trench is built just forward of the ordinary blow-off trench for the ash conveyor. This consists of a heavy section cast-iron worm (moulded by Vicars's patent system, which ensures true casting) working in a cast-iron U-shaped trough. Grids are provided opposite each flue, through which the clinker is fed to the conveyor. The framework of these grids is

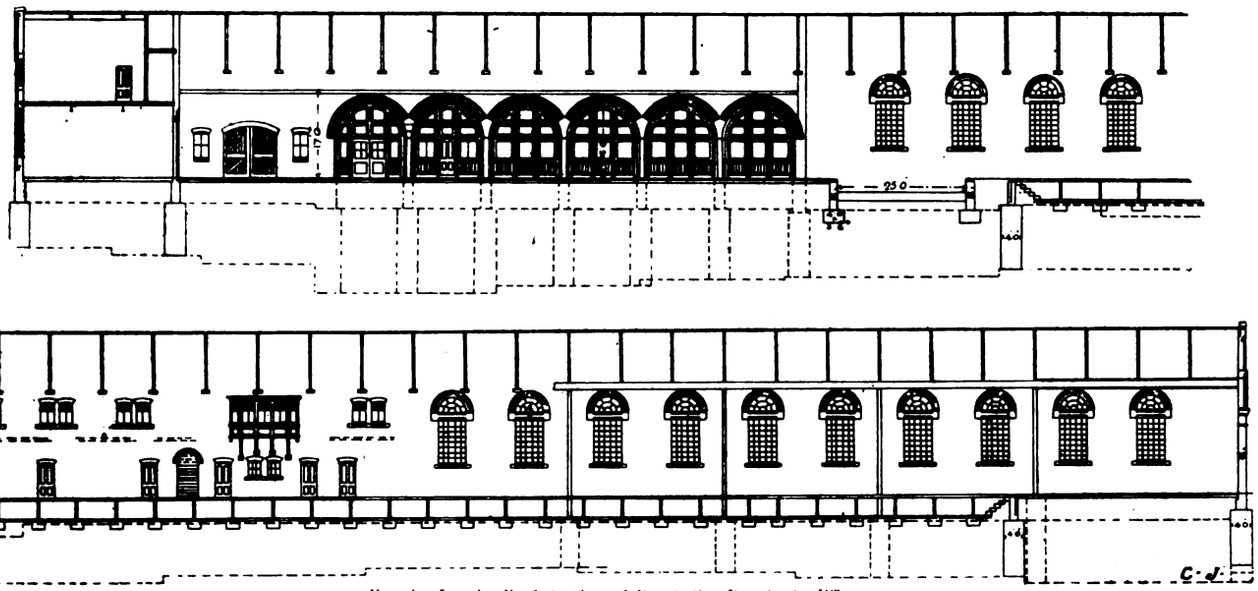

FIG. 4.—Longitudinal Section of Roath Car Depot, Cardiff.

of heavy cast-iron section, so that large clinker can easily be broken on same. The conveyor delivers the clinker and ash to a Vicars's double-chain type elevator, which discharges into a railway wagon standing on the same siding, by which fuel is brought into the stores, so that fuel can be conveyed to the boiler-house, consumed in the furnaces, and the residue removed from the site practically automatically. The general arrangement of this plant is shown in Fig. 9. It is driven by an electric motor through

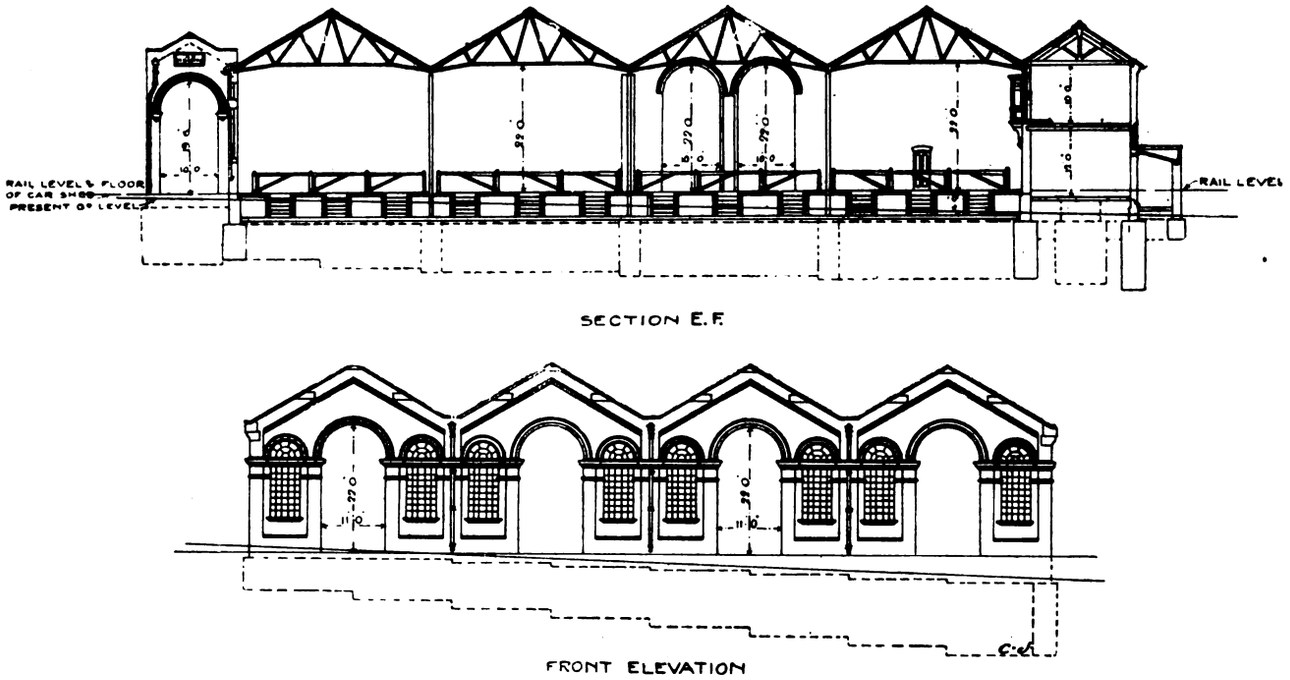

FIG. 5.—Front Elevation and Section of Roath Car Depot, Cardiff.

suitable countershafts, and was supplied by Messrs. T. and T. Vicars, 20, Bucklersbury, London, E.C.

As the coal-laden trucks are moved on to the station siding they are weighed bodily, a weighbridge being provided for this purpose upon the siding, with an office adjoining. After discharging their contents the trucks are reweighed, and an accurate check thus kept upon the amount of coal entering the station. No auxiliary weighing apparatus is employed, nor is it needed. It will be seen that the coaling and stoking arrangements have been carefully devised with a view to economising labour and providing an absolutely reliable check on the amount of coal consumed.

Boiler Feed Pumps.—In the pump-room there are installed three boiler feed pumps. These are of the single-cylinder direct (double) acting type, and were supplied by Messrs. G. and J. Weir, Limited, Cathcart, Glasgow. Each has a pump cylinder 8in. diameter and a steam-cylinder 10½in. diameter by 24in. stroke, its normal capacity being 6,000 gallons of water per hour when delivering against a boiler pressure of 160lb. per square inch. While the normal speed of the pump is reckoned at 12 double strokes per minute, should occasion demand it, this speed may be considerably increased in order to make up any abnormal deficiency in the feed supply. Fig. 10 illustrates one of these pumps. The pump ends are of cast iron, fitted with gunmetal liners, while the pump rods are of cold-rolled manganese bronze. The water-valves are of the Weir patent group type, of special bronze in gunmetal seats. The water pistons or buckets are of gunmetal, with ebonite packing rings. The valve gear is positive—*i.e.*, the steam-valve can never be in such a position that the pump will not start immediately when the steam is turned on. In these pumps the steam is used expansively, and the cut-off can be regulated from the outside while the pumps are working, thus making them extremely

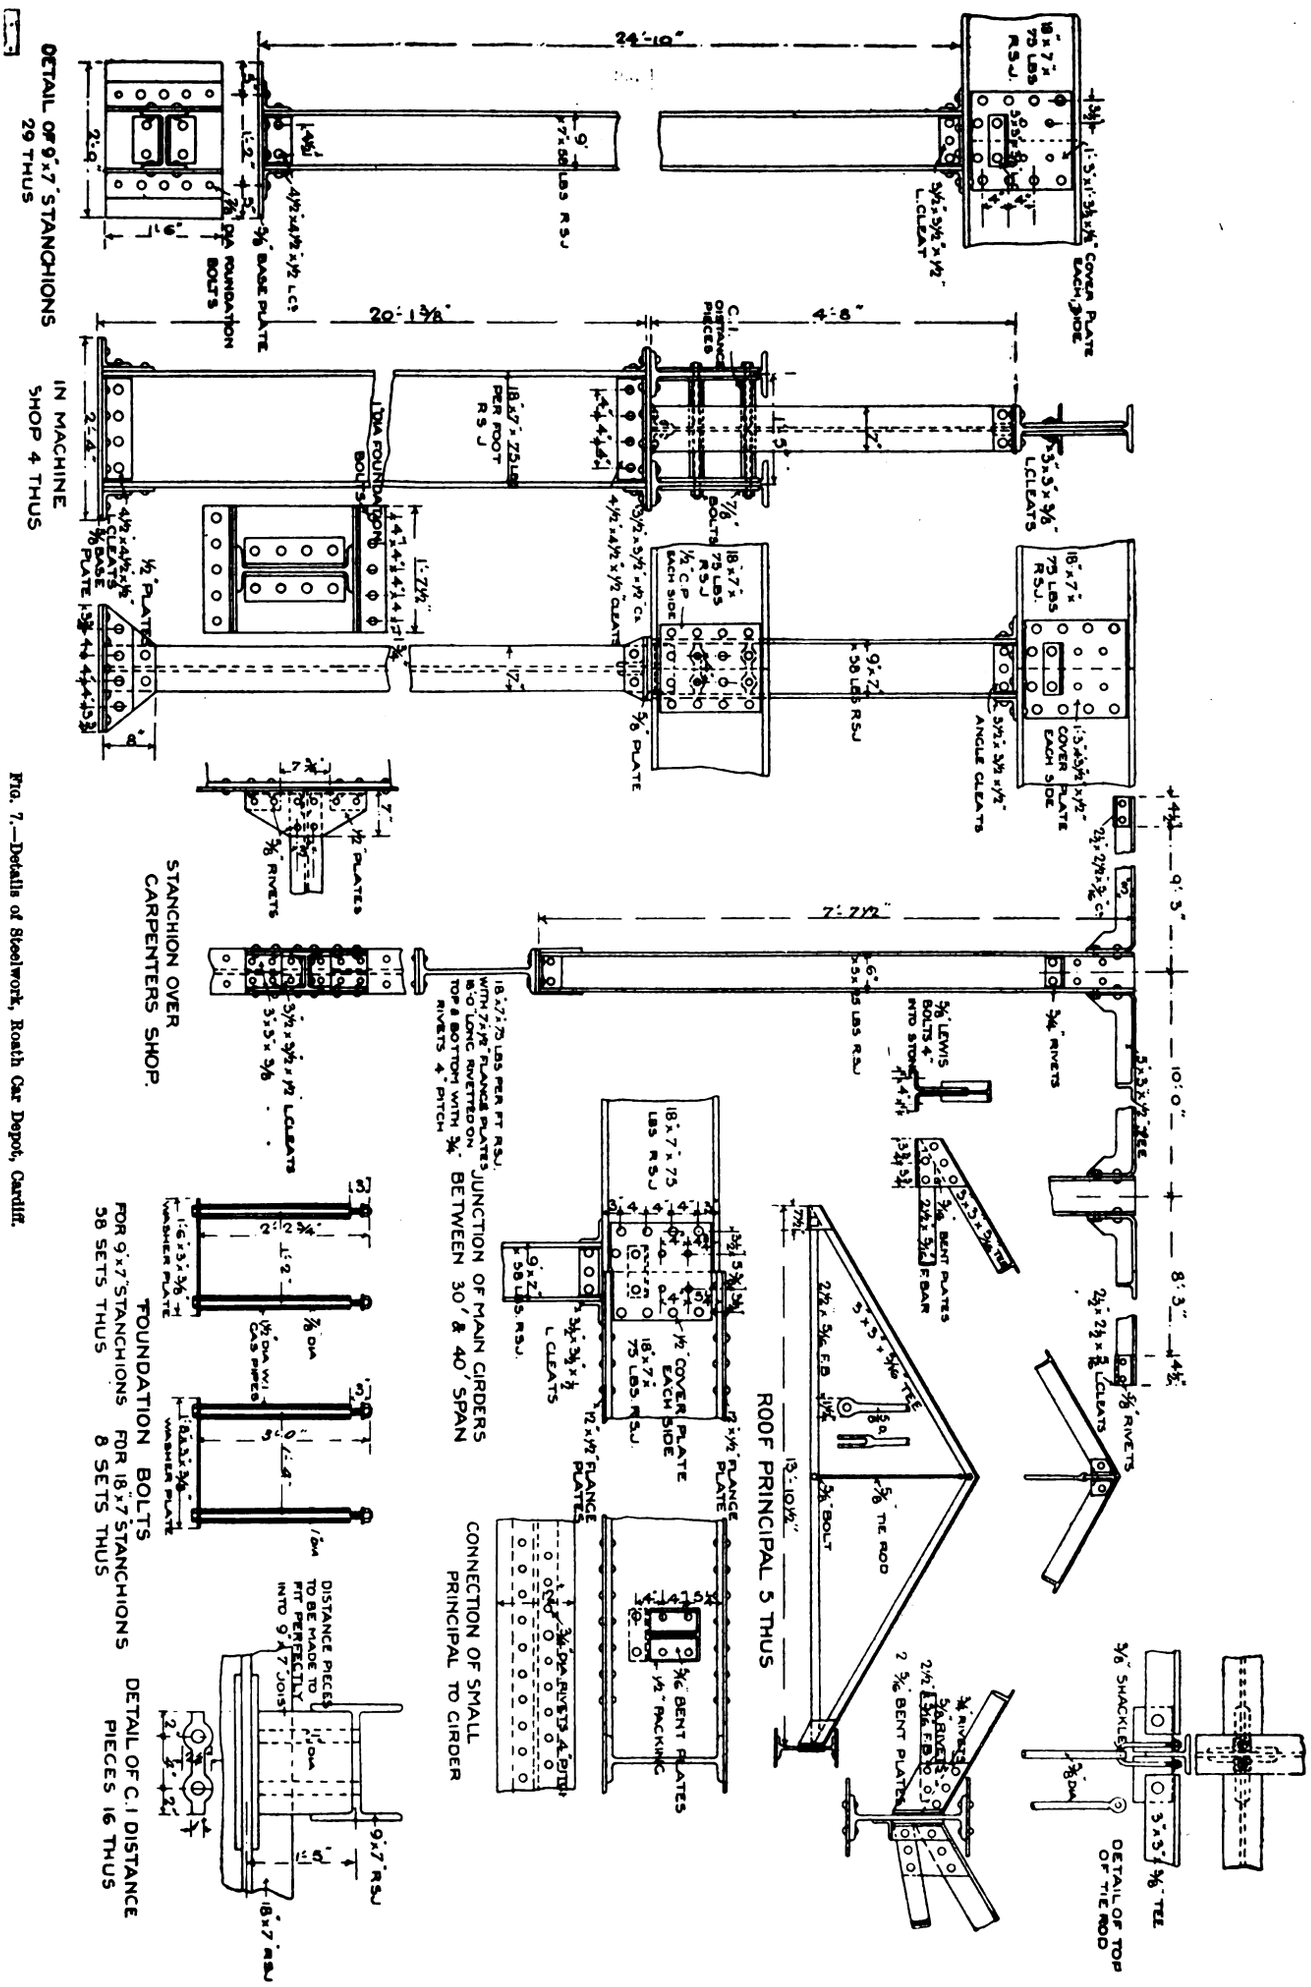

Fig. 7.—Details of Steelwork, Roath Car Depot, Cardiff.

economical pumps as regards steam consumption. All the working parts are readily accessible. There are also fitted in connection with these pumps three Weir economisers. The purpose of these economisers is to heat the feed water

Digitized by Google

by using the exhaust steam from the feed pumps. They are of the coil type, of cast iron, with coils of solid-drawn copper tubing. The arrangement of pipes in the pump-room is shown clearly in Fig. 11. It should be mentioned that these pipes were supplied by the Sir Hiram Maxim Electrical and Engineering Company, Limited. The pumps draw their supply of water from a large storage tank erected on the roof of the pump-room—either direct or through the Green's economiser as the exigencies of the moment demand. This storage tank is shown in Fig. 2. It is replenished from the town's service mains, no alternative source of water supply fit for boiler feed purposes being available on the site.

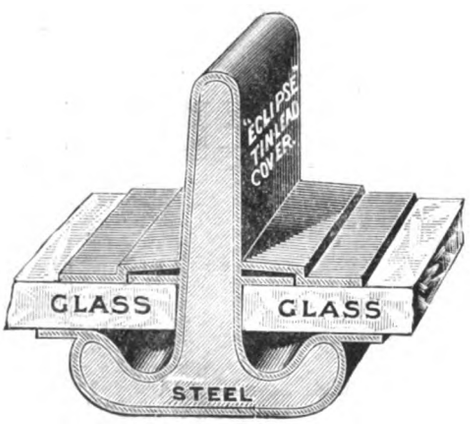

FIG. 8.—System of Glazing, Roath Car Depot, Cardiff.

Main Steam-Piping and Condensers.

The general arrangement of the steam-piping between the boiler-house and engine-room is shown in plan and elevation (Fig. 12), while the elevation (Fig. 13) shows the method of suspending the atmospheric exhaust piping. On referring to Fig. 12 it will be seen that the two main steam-pipes from the boilers are taken to the centre of the engine-room adjoining, where they connect—one at either end—to a two-way main, from which branch pipes are taken to the engines, the latter being arranged in two parallel lines to the right and left of the centre gangway. Thus it will be seen that the main steam-pipes form what may be described a semi-double ring, the double portion being suspended along the centre of the engine-room between two parallel rows of engines. Either of the branches constituting the double portion can be completely cut off, if necessary, without affecting the other. Expansion bends are provided in the centre of each of the branches, forming the double way, as shown in Fig. 12, while cones from which drain pipes are taken are provided both in the centre and at the ends. Along the centre of the engine-room the steam-pipes are suspended

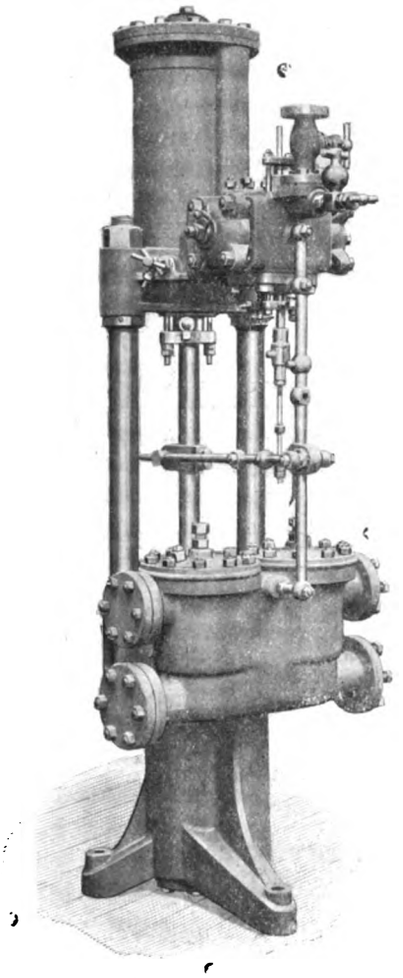

FIG. 10.—Weir Boiler Feed-Pump, Tramways Power Station, Cardiff.

from a gangway, the platform of which is on a level with the switchboard gallery, which it joins at one end of the room. The spindles of the main valves pierce the platform of this gangway, terminating at a convenient height above it in handwheels of the usual pattern. Thus ready access may be obtained to these valves from the switchboard gallery in an emergency. Access is also provided to the gangway from the engine-room floor level by means of

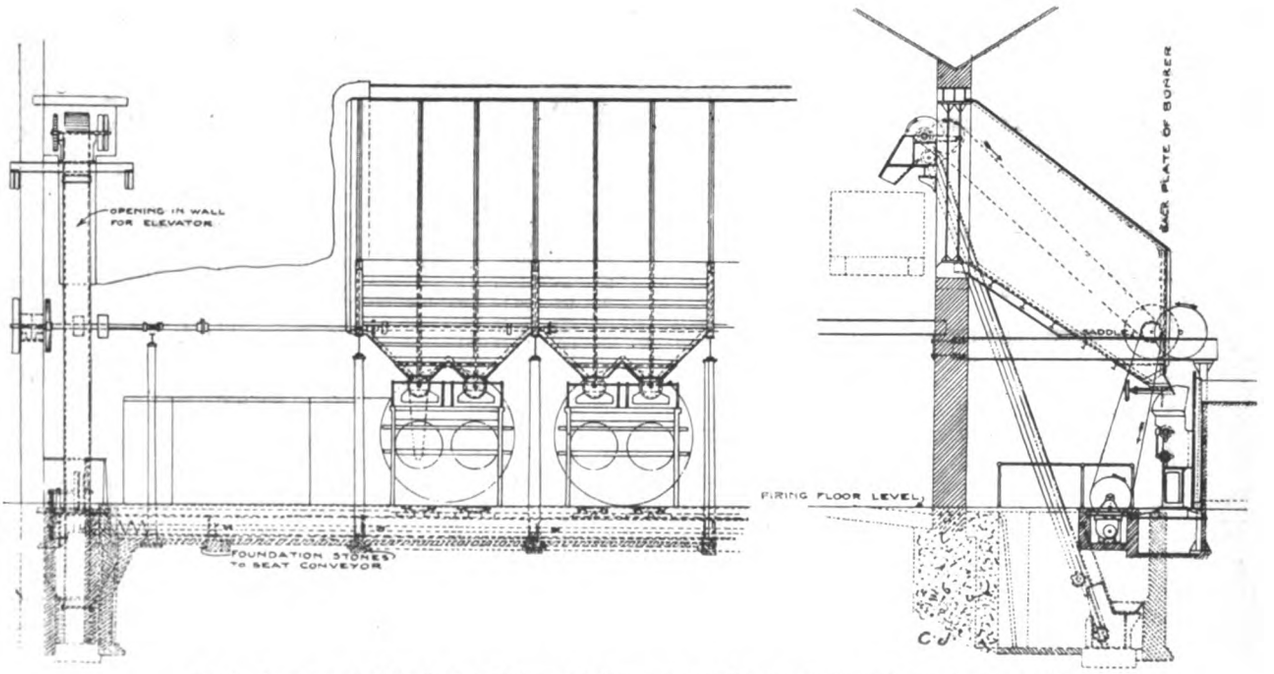

FIG. 9.—Arrangement of Mechanical Stokers, Ash Conveyor, and Elevator, Tramways Power Station, Cardiff

Digitized by Google

double stairways at either end. The whole arrangement is exceedingly neat, and provides maximum accessibility to the valves. From the switchboard little evidence of the steam-piping is seen, since it is hidden from view partly by the centre gangway and partly by the switchboard gallery itself, under which latter one of the branches from the boiler-house is suspended. We must not forget to mention that the main steam-pipes, both in the boiler-house and engine-room are steel sheathed over their asbestos lagging. The sheathing, which is composed of of oxidised steel, is put on in broad bands and screwed where the convolutions overlap at the edges. It is continued up to within a few inches of points where leakage is liable to occur—such as branch flanges and valves—the pockets provided for drainage purposes being also encased. The useful purposes of the sheathing are obviously, in the first place, to preserve, and in the second to protect, the lagging from mechanical injury or injury from dripping water. But it incidentally serves another purpose—that of lending an excellent finish to the pipes. Nowhere have we seen pipework which looks better than that under notice. It should be mentioned that all the steam-pipes were supplied and erected by the Sir Hiram Maxim Electrical and Engineering Company, Limited, Gracechurch-street, London, E.C., whose contract also included the exhaust pipes, circulating water and blow-down pipes,

feed-water filters, central gangway in the engine-room, cast-iron flooring and girders for supporting same to the floor of the engine-room, besides the feed pipes, as previously stated. We have purposely omitted the dimensions of the different pipes from the above description, since these are given in the illustrations referred to. Details of the construction of the central gangway in the engine-room are given in Fig. 14.

Digitized by Google

Now we come to the condensers. At present this portion of the plant is very incomplete. For the time being, in fact, the engines are exhausting direct into the atmosphere, the pipes conveying the exhaust steam outside the building being carried along the walls of the engine-room—one at either side—at a considerable height above the floor level. These pipes are not a temporary arrangement, but will eventually form an auxiliary means of exhaust. Jet condensers are in course of erection, into which it is intended that the engines shall exhaust under normal conditions of working. These condensers are placed below the level of the engine-room floor, each engine having its own condenser

driving from the cross-head. The necessary circulating water will be drawn from a huge cooling pond, the excavation of which is already completed, and the cement concrete lining nearly so. Around the upper margin of this pond there will be a shallow channel, which the partially cooled water from the condensers will enter on the side nearest the engine-room, and flow thence to the opposite side, where it will enter the pond through the channel provided, ready to be passed through the condensers again. The shallow channel round the pond serves, of course, to increase the cooling surface. A brook flows past the station, from which the pond will be replenished when necessary, but since its water is unsuitable for boiler feed purposes the condensed water will not be reused in the boilers. The cooling pond is seen in course of construction in foreground of Fig. 2.

Engine-Room Equipment.

Main Generating Plant.—There are at present installed four steam-driven generating sets, each consisting of a 500-h.p. engine coupled to a 300-kw. continuous-current dynamo. The engines are of the two-crank, cross-compound, vertical, condensing type, and were supplied by Messrs. John Musgrave and Sons, Bolton. Each has its own condenser driving from the cross-head. A steam starter is also provided to each engine, the spur wheel of which engages in a heavy flywheel. The generator is placed in the centre of the common shaft between the high-pressure and low-pressure sides of the engine, with the heavy fly-wheel adjoining it. These engines are of massive construction, looking big for their work. Bulkhead fittings containing electric incandescent lamps are attached to the inside faces of the vertical columns enclosing the cranks.

The generators are of the Westinghouse Company's multipolar railway type, each yielding 300 kw. at a pressure of 500-550 volts, when running at a normal speed of 100 revolutions per minute. They are of the direct-connected engine type—that is, the armature and the commutator are built on one cast iron spider, which is pressed and keyed direct on to the shaft of the driving engine. The generators are all exactly similar in size and construction. The armature of each is built up of soft-steel laminations, dove-tailed into the cast-iron spider and clamped between cast-steel end plates, the periphery being slotted to receive the armature coils. The latter are of copper bar, being forged to shape and insulated before being placed in the core slots; they are of such a form that they can be placed in position on the core without any bending or hammering, and they are held in position by hard wedges of insulating material driven axially into notches in the slots above them. This form of armature construction ensures the best and most permanent form of insulation, and also renders any part of the armature winding readily accessible, without interfering with any other part of the winding than the coil actually to be got at. There is an important feature in connection with the armature winding of the Westinghouse railway generator which ought not to be overlooked, and that is the provisions which are made therein for securing a perfect magnetic balance of the machine circuits, with the consequent acquisition of sparkless and cool running and the equalising of the magnetic stresses on the machine parts. Certain points of the armature winding, which are normally of equal potential, are joined together by additional conductors, so that in the event of there not being perfect balance in the respective armature

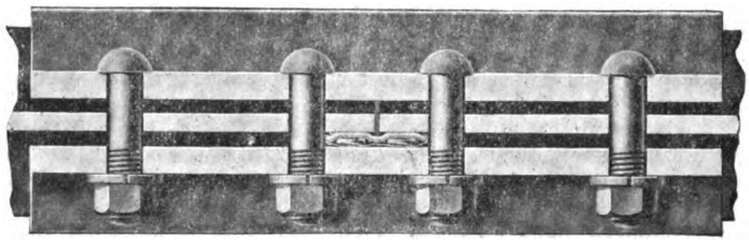

FIG. 17.—Arrangement of Plastic Bond, Cardiff Electric Tramways.

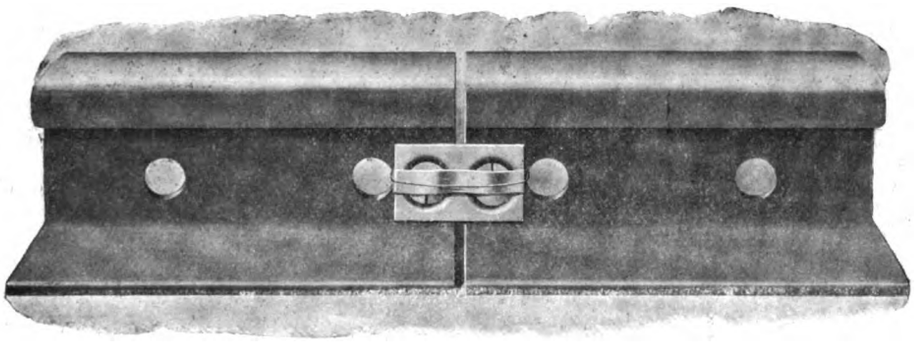

FIG. 18.—Arrangement of Plastic Bond, Cardiff Electric Tramways.

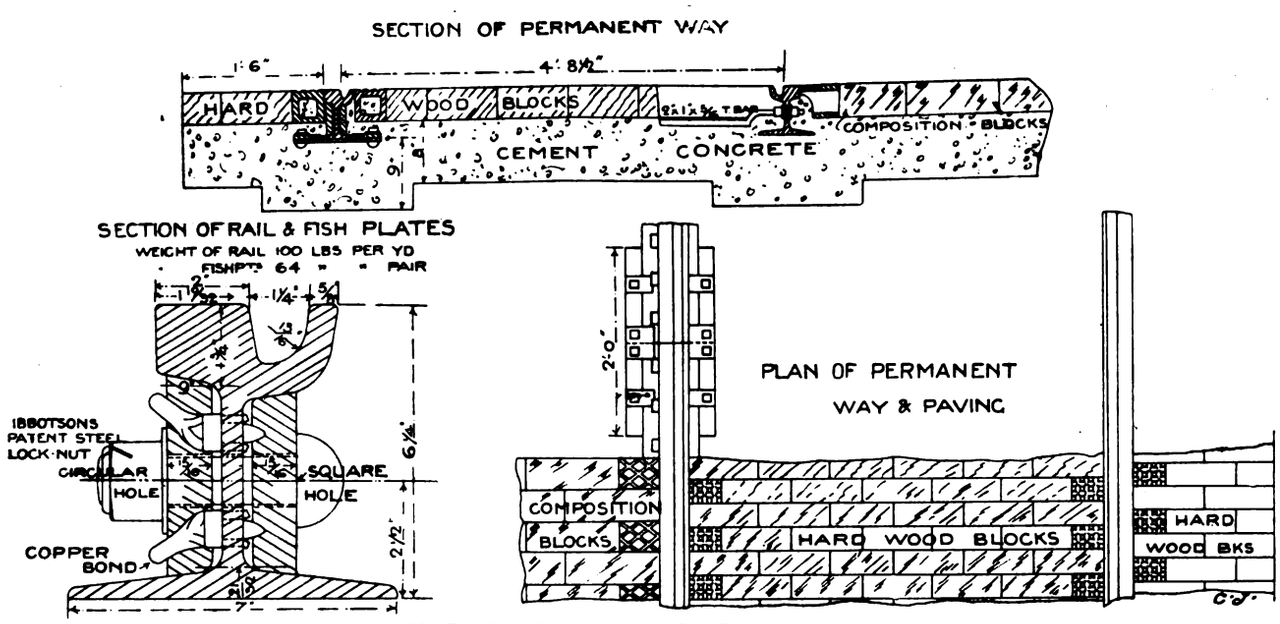

FIG. 19.—Details of Permanent Way, Cardiff Electric Tramways.

Digitized by Google

coils, the resultant current between them does not pass by way of the brushes, whereby injurious sparking and heating would be produced, but passes along the additional leads provided. The current in these conductors is of an alternating character, leading in some and lagging in others, so that only a very small current is really required for the perfect balancing of a machine. This method of balancing is particularly advantageous where, by wear in the bearings or any other cause, the armature of a machine becomes decentralised in the field. In this case, not only are the armature circuits balanced and sparkless running secured, but the heavy magnetic pull on the side of the armature nearest to the pole-pieces is eliminated. The balancing arrangement gives excellent results in practice, and has no doubt done a great deal towards making the Westinghouse railway-type generators so popular. The generator field consists of a series of pole-pieces, built up of soft steel laminations and cast on the inside of the enclosing field ring. This field ring is vertically divided, the two parts being set on guide plates. Gearing is fitted so that they can easily and quickly be drawn, thus throwing the whole of the machine open, and rendering all parts of either the armature or the field readily accessible. The fields are compound-wound, the windings being over-compounded to give a 10 per cent. rise in pressure between no load and full load. The shunt coils and the series coils are machine-wound on separate formers before being placed on the pole-pieces, over which they slide easily into position, and are held fixed by set-screws passing through lugs on the formers into the field ring. The commutator is built of the best materials for securing high conductivity and even wear under the brushes. It is carried, as stated, on an extension of the armature spider, and is of ample size for the current output of the machine. The brushes are of carbon, the brush-holders being of a strong and serviceable spring pattern, supported by brackets from a ring concentric with and, in its turn, supported by the field ring. The usual form of hand-wheel and gearing is used for moving the brush ring and adjusting all the brushes simultaneously. This is shown in Fig. 15, which is a view taken of one of the generators before it left the erecting shop.

Motor-Generator.—This was supplied by Messrs. D. Bruce Peebles and Co., Tay Works, Bonnington, Edinburgh, and consists of two of their multipolar four-pole continuous-current machines, coupled end to end, and mounted on a combination cast-iron base-plate, the heavy flywheel being supported by intermediate bearings between the armatures. The combined set runs at a speed of about 500 revolutions per minute when supplied with current at a pressure of 500 volts across the motor terminals, the generator developing an output of 600 amperes at any voltage between 100 and 140. The set is also arranged so that by supplying current at a pressure of 100 volts to the terminals of the low-tension machine, the high-voltage machine will be capable of developing its output at a pressure of 500 volts. The set is used for the following purposes: (1) when receiving current at 500 volts from the tramway 'bus bars and running as a motor, the generator to be used for charging the battery of accumulators; (2) when running as above, the generator to be used for lighting the power station and car depôt direct and independent of the battery; (3) when receiving current from the battery at 100 volts, the generator to develop current at 500 volts for line-testing purposes and shunting the cars in car depôt, when the motor-generators are shut down.

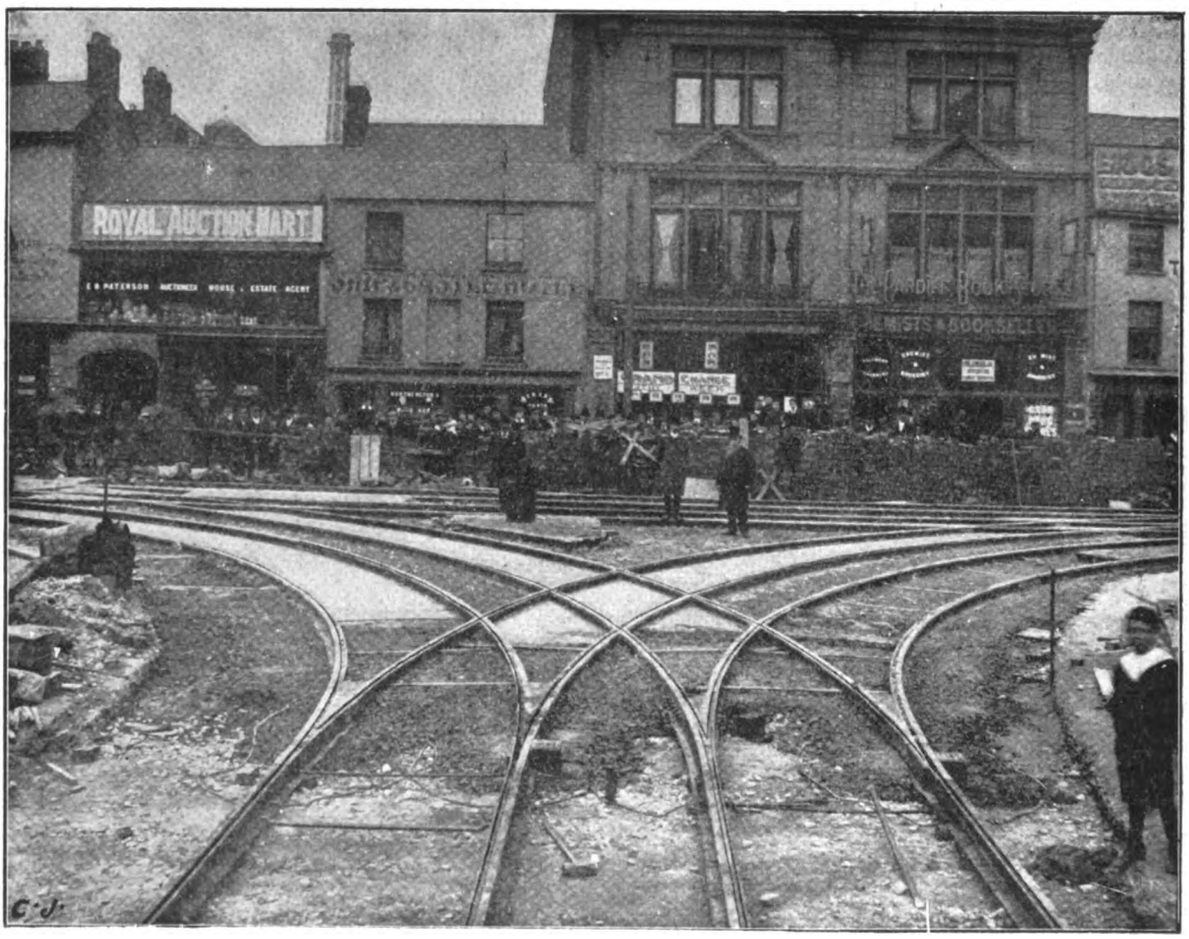

FIG. 20.—Junction with St. Mary-street and Wood-street, Cardiff Electric Tramways.

Both the high and low voltage machines are of Messrs. D. Bruce Peebles's standard construction, the magnets being shunt-wound in each case. The armatute is of the multipolar slot-wound type with cylindrical winding built up on spider of rigid design, and having fan blade ventilating ducts distributed at equal distances throughout the core, thereby ensuring ample ventilating surface. The core plates are of annealed Swedish charcoal iron individually papered and varnished, the slots being thoroughly insulated and tested at a pressure of 5,000 volts. There are no joints at the back end of the winding, and each coil is previously prepared and shaped on machine jig. There are no joints in the whole armature except in the commutator end. The commutator is a special feature of these machines,

Digitized by Google

being built up of high-conductivity drawn-copper bars, constructed under heavy hydraulic pressure and insulated with pure India mica. The magnets are of cast steel, and are split on a horizontal plane, so that ready access may be obtained to the armature. By means of the firm's special non-sparking pole-tips, the machine is rendered sparkless at all loads from no load to 25 per cent. over full load without alteration in the position of the brushes. The brushes are of carbon having a low current density. The bearings are of the self-aligning type, fitted with automatic oil ring lubrication. The whole machine has a handsome and workmanlike appearance, and is a sample of the many other well-designed and constructed machines turned out by the firm in question. Fig. 16 shows the general arrangement of the set.

Main Switchboard.—The traction switchboard is erected in a deep recess in the permanent end wall of the engine-room adjoining the offices, and on a level with the engine-room gangway previously described. It is of the standard type introduced by Messrs. Ferranti Limited, Hollinwood, Lancs., being a fine example of its kind. The switchgear is of particularly solid construction, its arrangement, moreover, combining the many advantages, both as regards electrical efficiency and economy of space occupied, so well defined in the Ferranti type of switchboard. Seven feeders are at present connected to the board, and four generators, but it provides for a large increase in the number of feeders, and also for the extension generators now on order. The measuring instruments are of the edgewise pattern, and the field resistances, which latter are erected below the switchboard gallery, of the Westinghouse circular type. We hope to refer to this switchboard again in a subsequent article.

Station Lighting.—The wiring of the station buildings was done by the Corporation's own staff, Simplex conduits being used. Davy arc lamps are installed in the engine-room, and owing principally to the height at which they are suspended, a remarkably uniform diffusion of light is obtained. The station lighting switchboard is built in a separate recess along the main switchboard gallery.

Accumulators.—A battery, consisting of 56 cells of the Tudor L B 31 type, capable of giving 210 amperes for 10 hours or 540 amperes for three hours at 100 volts, has been installed. The cells are contained in lead-lined wood boxes. This battery will be used exclusively for the station lighting and purposes indicated in the paragraph headed "Motor-Generator." A milking booster set is provided, this being placed in the corner of the engine-room nearest the accumulator-room.

Engine-Room Telegraphs.—A complete system of engine-room telegraphs has been installed. The switch by which these telegraphs are operated is attached to a pillar facing the traction switchboard. The signals appear as illuminated figures on an oblong panel, behind which the illuminating lamps are fixed. The figures represent the different engines, and may be illuminated individually at will from the switch pillar according as it is desired to start up or slow down any particular set. There are three receiving panels, two at the switchboard end of the room and the third on the opposite end wall. The switchboard attendant is, therefore, enabled to give the necessary instructions to the engine-drivers without leaving his post.

FIG. 21.—Crossing and Junction, Bute-road and Euston House-street, Cardiff Electric Tramways.

Extension Plant.—The extension plant on order includes two steam generators, each set consisting of a 1,000-h.p. Musgrave engine coupled to a 900-kw. Dick-Kerr dynamo. The foundations for these sets are already in. As explained elsewhere, the station will eventually supply current not only for traction purposes, but also to an extensive network of lighting and power mains. However, this portion of the scheme is yet in its initial stages, although the same generating plant will serve to supply both networks.

Outside Work.

Track.—The trackwork is laid on a cement concrete foundation 8in. in depth, with an extra depth of 3in. under the rails and for a distance of 6in. on either side of same. A rail of the girder type has been used throughout, weighing 100lb. per yard. The rails are 6¼in. in depth, and the width of the bottom flange is 7in., the groove of the rail being 1¼in. wide and 1¼in. in depth. The rails are jointed

Digitized by Google

with fishplates, each pair weighing 64lb., and are bolted to the rails with six 1in. fishbolts fitted with Ibbotson's patent lock nuts. The rail joints are also further secured by Askham's patent sole-plate, 2ft. by 11in. by ½in., fastened with four single and two double clips by ⅞in. bolts. The tiebars first used were of the ordinary type of flat bar section, but those used more recently and on the reconstruction are of cranked T iron specially designed by Mr. Harpur for the purpose of permitting the wood paving between the rails being carried over same, thus enabling the paving to be more expeditiously executed, and also giving the same a neater appearance when finished. The points and crossings used on the new routes were obtained partly from Messrs. Askham Bros. and Wilson, of Sheffield, and partly from Messrs. Hadfields, of Sheffield, oak, the latter being obtained as prismatic oak blocks, which blocks are used on inclines where a better foothold for horses is required. A considerable portion of the spaces between the up and down roads is paved with a composition block obtained from the Sanitary Block and Tile Company. The Jarrah and deadened redgum timber is obtained in 9 by 3 planks by the Corporation, who have laid down a sawmill for converting same into blocks, one of Temperley's patent automatic cross-cut saws being used for the purpose, a special equalising machine obtained from Messrs. Ransome and Co. being also used for planing the planks to a uniform thickness. The blocks are all cut to a uniform depth of 4in., and are laid with close butt joints. In order to minimise the great wear of the blocks along the sides of the rails, chilled cast-iron blocks are laid

FIG. 22.—Plan of Feeders. F.P., Feeder Pillar; N.F.P., Negative Feeding Point; S.B., Section Box; Cardiff Electric Tramways.

the latter firm supplying all this class of material for the reconstructed portions of the routes and manufacturing same out of their patent manganese steel. To secure the electrical continuity of the rails, the joints are bonded with copper bonds outside the fishplate and plastic bonds between the fishplate and the web of the rail. The rails are also cross bonded with copper bonds. The greater part of these bonds were supplied by Messrs. Robert W. Blackwell and Co., Limited. The plastic bond used is of the latest type. Its arrangement is shown in Figs. 17 and 18.

The different sections of the tracks are paved with the following timbers: Jarrah, Alcott's deadened redgum, and alternately with the wood and other blocks along both sides of each rail. Details of the permanent way are shown in Fig. 19, while Figs. 20 and 21 show the track in course of construction.

Mains.—What may be termed the feeder point and distributor system of mains has been adopted in connection with the Cardiff electric tramways, the feeder pillars to which the feeders from the main switchboard are run being really distributing boxes, from which the distributor cables radiate to the actual feeding points The positions of the various feeder pillars and section boxes are shown on the accompanying plan (Fig. 22).

NOTES.

Western Society of Engineers.—We beg to acknowledge the receipt of the above society's *Journal* for April, which is published bi-monthly in Chicago. The present issue contains reprints of some useful papers with the discussions thereon, including one on "Mechanical Filtration" by Mr. R. E. Milligan.

Standardisation.—A commission has been formed in connection with the Institution of Civil Engineers, the Institution of Mechanical Engineers, the Institution of Naval Architects, and the Iron and Steel Institute, to consider the question of standardising tramway rails and other sections. Among those composing the commission are Sir John Wolfe-Barry, Sir Douglas Fox, Mr. W. Harpur (of Cardiff), and Mr. C. F. Wylie (of Sheffield).

Effect of Light on the Eyes.—It will be interesting to electrical engineers to hear that a Russian specialist has decided that the electric light has less damaging effect on the eyes than other forms of artificial light. Taking as his basis of deduction the number of times the patient closed the lids of his eyes, he found that the electric light was even less effective than the sunlight. To give the actual figures, the lids closed 6·8 times in a minute with candle light, 2·8 times with gas light, 2·2 times with sunlight, and 1·8 times with the electric light.

Multiplex Telegraphy.—A Berlin message says that a new system of multiplex telegraphy, which is the invention of Dr. Donald Murray, is being tried at the Berlin central telegraph station, and should the German Telegraph Department report favourably on it, the system will first be installed between London and that city. It is said that Dr. Murray claims to be able to send 12 messages at a time, and among other advantages which he makes for his apparatus he claims that it does away with the necessity of transcribing the messages received from the Morse code into ordinary writing.

Book Received.—"The Generators of Electricity at the Paris Exhibition of 1901," by C. F. Guilbert. We have received from the publishers, of 3, Rue Racine, Paris, the above volume, which will be of enormous interest to all electrical engineers concerned with the design of dynamos and other electrical apparatus. The volume, which consists of almost 800 pages, contains illustrations of all the large machines on view at the exhibition in question, with a large number of diagrams of their details of construction. As a work of reference this book may be looked upon as indicating the exact state of the art at the end of the nineteenth century.

Telephony in Canada.—The principal clauses of the Bill recently brought in by the Dominion Government for regulating telephones and telegraphs in Canada are now available. It seems that the Government reserve the right after two months' notice to assume possession of the property of any telephone or telegraph company carrying on business in that country; and in the event of a difference arising as to compensation, reference is to be made to three arbitrators. Another provision is that the lines shall be so constructed as not to interfere with the public use of roads and highways, or impede free access to any building. Tolls may be fixed for either the whole or any particular part of a company's line, but such tolls are to be uniform to all persons, and must be approved by the Governor in Council. Another clause makes it compulsory upon a telephone company to supply telephone connection to any applicant upon the payment of lawful tolls.

Measure of the Electrolytic Diffusion of the Ions.—In the current number of the Chemical Society's *Journal*, just issued, will be found a short account of a method brought forward by Mr. Paolo Straneo for measuring the coefficient of diffusion, D, the transport number, n, and the relative mobilities, u and v, of the ions of an electrolyte, which obviates the use of diaphragms and requires only very small differences of concentration, besides being very rapidly carried out. The principle of the method is to place the electrolyte to be examined between two horizontal electrodes at a short distance apart, and by means of an electric current of convenient density to cause a displacement of the electrolyte from the top to the bottom; from the variations of the concentration of the electrolyte in the neighbourhood of the electrodes, the values of D, n, u, and v can be calculated. A test experiment with zinc sulphate solution between amalgamated zinc electrodes has given good results.

Electric Fire Appliances.—At the sixty-sixth annual general meeting of the Liverpool, London, and Globe Insurance Company, Sir Wm. H. Tate, Bart., the chairman of the company, made some remarks which, we trust, are original, as we should not like to think that the expert advisers of the above company agree with their chairman. He stated that "the extended use of electricity had no doubt been one cause of the increased number of fires, especially abroad, as faulty installation was sure, sooner or later, to result in an outbreak." That there have been electrical fires due to faulty installations we should be the last to deny, but all the statistics which have been collected by the fire insurance companies in the United States, where such faulty installations are much more frequent than in this country, show that even with this extra risk the number of fires caused by electricity is a small proportion of those caused by other illuminants. We think that the chairman of the above company would do well to look into his statistics before making general statements which are as misleading as they are absurd.

High-Voltage Transmission.—What we believe to be the first case of power transmission in railway practice at more than 26,000 volts is that which will shortly be brought into operation at Indiana, U.S, where the Union Traction Company propose to have power supplied over 32,000-volt three-phase transmission lines. The railway system is at present being supplied over 14,000-volt lines. The interurban system of the company already has a total length of 97 miles, and this is shortly to be added to by 75 miles of new line, for which the 32,000-volt transmission will be used. The transmission line will run north from the power station at Anderson to Alexandria, and then west to Tipton, following the railway right of way. At the latter place there will be a high-tension switching station, at which the load can be thrown on to either one of the two high-tension transmission lines that will be provided. The longest distance of transmission will be 60 miles. This is said to be a considerable advance in voltage and distance over any power transmission yet carried out in the Eastern States, though in California this distance and voltage have been equalled in many and exceeded in at least three prominent cases.

Mechanical Engineers' Conversazione.—A very successful conversazione was given by the president and council of the Institution of Mechanical Engineers at the institution buildings, Storey's-gate, Westminster, on Friday night. Among the guests were Lord Strathcona and Mount Royal, Lieut.-General Kelly-Kenny, Rear-Admiral Durnford, the Bishop of Rochester, the Mayor of Westminster (Colonel Probyn), Lieut.-General J. F. Owen, Mr. Balfour-Browne, K.C., Sir W. de W. Abney, Lieut.-Colonel Yorke, Lieut.-Colonel von Donop, Sir E. Bradford, Mr. Fletcher Moulton, K.C., M.P., Mr. Charles Hawksley, Mr.

Digitized by Google

R. W. Dana, Sir John F. L. Rolleston, M.P., Mr. D. J. Dunlop, Captain Tamari, Sir Walter Peace, Sir Horace Tozer, and many other representatives of learned and scientific societies The band of the Scots Guards, conducted by Mr. F. W. Wood, played in the large hall, while a programme of vocal music was performed in the library, the vocalists being Mrs. Montague Fordham, Miss Gertrude Calvert, Mr. Samuel Masters, and Mr. Robert Radford. In the large hall a number of interesting slides showing the process of ice-breaking in the Arctic regions were shown and described by Mr. Arthur Gulston, of Newcastle-on-Tyne.

German Electric Railways. — Some valuable statistics have recently been published which show the state of the public electric railway and tramway interests of Germany up to Oct. 1 last year On this date 113 German cities, against 99 in 1900, had electric traction, with a total length of roads of 1,940 miles, equal to 2,844 miles single track. The total capacity of the generating electric machinery in use for traction was 108,021 kw., as against 75,608 kw. in 1900, excluding storage batteries. The increase in the use of storage batteries was still greater ; their power was 25,531 kw. at the end of October, 1901, as against 16,890 in 1900. The total capacity of generating machines and batteries together for traction was, therefore, 133,552 kw. For light and traction together the total capacity of generating machines and storage batteries was 486,120 kw. The average number of kilowatts per motorcar was 15·7, against 15·1 and 14·3 in 1900 and 1899. These averages have, therefore, remained nearly constant, although the values of single roads differ greatly from these averages. Of the total 2,844 miles single track, only 445 miles are owned by municipalities, but even this is in part rented to private companies. The above figures do not include the statistics of private roads, with the exception of the Berlin-Zossen experimental railway.

New Type of Submarine.—Particulars are to hand of the new submarine boat invented by Mr. Claude Goubet, which has just been sold to the newly-formed British Submarine Boat Company. It is said to differ very widely from the newest "Holland" type, to which the present British submarines belong. While the latter have a reserve buoyancy when submerged, and are kept under by means of horizontal rudders, the Goubet boat possesses no reserve buoyancy when beneath the water, its weight equalling its displacement. The new type, in fact, weighs nothing when submerged, and it is said that the addition of a very small weight will set it sinking. In order to keep the boat on an even keel and prevent it either rising or sinking, the inventor has devised an arrangement which pumps water from a forward tank to one situated aft, and *vice versâ*. The method of working is described as follows : Should the vessel incline in any direction a pendulum swings forward, and in so doing forms a connection between a motor and the batteries ; the former at once commences working the rotary pump in a direction which causes the water to flow through the pipes from the lower tank to the higher, until the addition of water to the latter is sufficient to bring both the boat and tanks level again. The pendulum swinging straight then cuts off the electric current and the motor instantly stops.

Alternating-Current Meters.—The American Patent Office have recently issued four patents relating to alternating-current meters, all of which were granted to German inventors. Mr. G. Stern, of Charlottenburg, is responsible for two which are both concerned with a new arrangement of actuating the windings of an alternating-current meter. As applied to an induction meter, there are two measuring systems, each consisting of two series and one shunt winding, the windings being arranged in co-operative relation to the usual short-circuited armature operating a counter. The current windings are so connected and arranged that the resultant of the current fluxes in the two systems are displaced in phase from one another by 150deg.; and the shunt winding is connected and arranged to generate potential fluxes displaced in phase from one another by the same angle, the potential flux of the non-inductive load lagging in one system behind and the other leading the current flux. The second patent covers connections such that the displacement of the current is 30deg. from its impressed E.M.F. Two other patents, taken out by Mr. Schroltke, of Berlin, describe a meter of the induction type, consisting of a four-pole field surrounding a short-circuited armature, which latter actuates a counter. On two opposite poles is a winding in series, with one of the working conductors and also a short-circuited secondary winding. On the other two poles is a potential or shunt winding, in series with which is an inductance or a condenser.

Local Veto.—An unsuccessful attempt was made in the House of Commons on Thursday week to amend Standing Order No. 22, the effect of which would be to abolish the veto at present vested in the local and road authorities in regard to the construction of tramways in this country. The motion was brought forward by Mr. Chaplin, who denounced the present law, which makes the consent of the local authorities concerned an absolute condition before any Tramway Bill can even be introduced into Parliament, as having led to "considerable scandals." What he proposed was this: that proof should be given before the committee on the Bill that the promoters had either obtained the consent of the local authority or that it had been withheld, and that if, in the opinion of the committee, such consent had been unreasonably withheld and ought to be dispensed with, they should report accordingly. Naturally enough, the proposal did not gain a favourable hearing, and it was opposed by practically all the representatives of the metropolitan borough councils and the majority of the provincial local authorities. The chief argument adduced against the amendment was that if the local veto were abolished, great injustice would be done to the local communities, who would be put to needless expense in employing parliamentary counsel and opposing schemes which affected them. In fact, nearly all the speakers on the question declared their intention of voting against the amendment, and ultimately it was rejected without a division.

Birmingham Local Section.—The report of the committee of the above section of the Institution of Electrical Engineers for the past year was presented to the annual general meeting of the section, held at Birmingham on the 14th inst. It is noteworthy that at the six meetings held in the past session the papers read were in every case illustrated by demonstrations with apparatus or lantern. The Council of the parent institution has decided to include all the communications which have come before the section at these six meetings in the *Journal*, either in abstract or in full. We further gather from the committee's report that the membership has been increasing steadily, the total number of members of all classes now being 152, as against 123 at the end of the previous session. For the coming session the committee invite offers of papers, such offers to be in the hands of the hon. local secretary in time to enable the committee to draw up a complete programme for issue to the members before the first meeting in November. The committee wish again to remind the members of the absolute necessity of receiving papers from local members if the section is to continue its

Digitized by Google

existence. The programme of the current session was very largely arranged for by officers of the section. The following is the list of officers for the session 1902-3: past-chairman, Prof. Oliver Lodge, D.Sc., F.R.S.; chairman, Mr. Henry Lea, M.I.C.E.; vice-chairman, Mr. J. C. Vaudrey, M.I.C.E.; committee, Messrs. Fredk. Brown, Alfd. Coleman, Alfd. Dickinson, R H. Housman, W. O. Rooper, W. E. Sumpner, D.Sc, A M. Taylor, and R. Threlfall, F.R.S.; hon. secretary, Mr. D. K Morris.

Electrolytic Extraction of Copper.—An apparatus for the extraction of copper from sulphuric ores by an electrolytic process is the invention of Mr. Lehonin, a Russian engineer, and one of the claims he makes for his method is that it does not necessitate the preparatory roasting of the ore. The apparatus is especially adapted to localities where fuel is scarce, but where water is easily obtained. After the ore has been picked and crushed, it yields almost pure pyrite, which is submitted to a treatment with sulphuric acid. By this means the green vitriol dissolves, and the solution flows into a row of stepwise-connected cells, making it possible to use currents of different power. The arrangement consists of a zinc box containing cells, in the first of which is placed one cathode of any desired metal; in the second, divided by a partition, are two cathodes; in the third, with two partitions, are three cathodes; and in the fourth, with three partitions, are four cathodes. The electrolyte flows consecutively through all the elements. In the first apparatus, which has the largest surface—*i.e.*, 25 square decimetres—the current is 50 amperes, or two amperes to one square decimetre; in the second apparatus the current density is one ampere per square decimetre; in the third, three fourths of an ampere, and in the last, half an ampere. The concentrated solution enters the first apparatus, leaving a sediment of copper, then flows into the second, and so forth. The solution contains copper as well as iron vitriol, but the iron vitriol does not separate unless the solution contains at least 5 per cent. of copper. The copper received on the cathode is ready for refining, while the sulphuric acid obtained from the apparatus can be used over again.

Comparative Cost of Coal and Gas.—Some valuable data of interest to all power users are obtainable from a series of tests which Prof. Henry G. Cox has recently made in the States in order to determine the comparative cost of gas and coal fuel. The tests were carried out in one of the large manufacturing plants of Indianapolis, where half of the boilers were fired by natural gas, the rest by coal. For the purposes of the experiments the price of natural gas was taken at about 4d. per 1,000 cubic feet, and the coal used was a West Virginia screenings variety, costing about 9s. a ton. The coal was good, high in heat value, low in ash, iron, and sulphur, and in this test it won over the natural gas by the amount of above 30 per cent. It is customary in boiler tests to find the cost of evaporating 1,000lb. of water to be used simply as a basis for comparison, and in the above test the cost of evaporating 1,000lb. of water by using natural gas was about 8½d., while coal evaporated the same amount at a cost of under 6d. Another test was made last November with Indiana coal, and in this case also, not only did the coal again make power about 30 per cent. cheaper than natural gas, but the efficiency of the boiler and stoker was so much greater that the coal evaporated 1,000lb. of water at a cost of only just over 3d. In giving the above results before a scientific society the other day, Prof. Cox stated that they came as an agreeable surprise to him, for, though many engineers claimed that with some good make of stoker carefully-fired coal could generate power as cheaply as natural gas, none were prepared to see the coal make it so much cheaper. His conclusion is that in dealing with the power problem, natural gas is not to be taken into calculation as a permanent commercial proposition.

Metallisation of Textiles.—A method of metallising textiles electrically, which is said to afford the possibility of impregnating the thickest piece of cloth, either thoroughly or only on its surface, with any kind of metal, has been invented by Dr. K. Donilowsky, of Russia. The object is attained by an electrical process of separation of the different salts from a given metal and by accumulation of the separated metal in a cathode. From an interesting account of the process we gather that for metallisation there can be used copper, iron, silver, nickel, and, in general, any metal which can be separated from its salts by electrolytical manipulation. Before the process of metallisation the textile has to go through a preparatory treatment, which consists in impregnating the cloth with a solution of the salt of a certain metal—for instance, with sulphuric acid of copper or oxide of silver, etc. After the cloth has been impregnated it is submitted to a certain treatment with oxidised sulphur, which causes the metal to be separated from the solution in a sedimentary mass, which, being very fine, intrudes the cloth, uniting closely with its fibres, and also settling down on the surface of the cloth. When the cloth is thus prepared it is ready for the process of metallisation, and for this purpose it is put into an electrolytic tub filled with a solution of the salt of the kind of metal in which the cloth shall be metallised, and brought in contact with the positive surface of an electrical device. The power of the current, as well as the contents of the tub, has to be regulated for each case respectively. The result which is claimed for this operation is a cloth perfectly impregnated throughout its thickness, as well as on its surface, with a certain metal in crystallised or in any desired form, which has so uniformly united with the substance of the cloth that the latter is perfectly metallised.

Low-Voltage Lamps.—At a recent meeting of the Société Française de Physique a paper was read on "The Electric Light by Incandescent Lamps by Carbon Filaments on the Economiser System of Weissmann-Wydts." The communication was by Mr. G. Weissmann himself. The idea of the inventors is to vary the voltage on incandescent lamps with candle power so that carbon filaments of uniform thickness can be used with all types. The reason for this is stated in the paper to be that the efficiency of the lamps depends on the diameter of the filament. The figures given by the author in support of this are as follows: With a 10-c.p. 110-volt lamp the average consumption is stated to be four watts per candle, whilst with a 5-c.p. lamp it works out at five watts per candle. If, on the other hand, a 110-volt 32-c.p. lamp is used, an average consumption of three watts per candle is said to be obtained, or 2·5 watts per candle with a 50-c.p. lamp, etc. The author's conclusions are that the efficiency is dependent on the candle-power with the ordinary types of lamps, and that if he could use a short length of thicker filament for the small candle-power lamps, he would get a much higher all-round efficiency. In order to do this he has designed, with the assistance of Mr. Blondel, a system of supplying all the lamps on an installation through small transformers. One transformer is provided for each group of lamps, and the voltage can in this way be decreased to that required. For instance, the 10-c.p. lamps would be worked at 22 volts, and the 50-c.p. lamps at 110 volts. The transformers are so connected that they are out of circuit when the lamps are not in use. It will be seen that the system would only be

Digitized by Google

available on alternate-current circuits, and we personally are inclined to think that it is to the lampmaker, rather than to the transformer maker, that we must look for the desired improvements in the efficiency of high-voltage lamps.

Lightning Conductors.—In the course of a long article in the current number of the *Wisconsin Engineer*, Mr. G. W. Wilder remarks on the numerous attempts which have been made to find out the probable value of the current which traverses a lightning conductor during a discharge. Until recently it was thought to be some function of the difference in potential between the earth and the clouds only. Now it is known that with exceedingly high frequencies the cross-sectional form, and the kind of material which constitutes the conductor, are of much more importance. On account of the shortness of duration of a lightning discharge, the current in a copper conductor must be enormous, the writer thinks, in order to produce some of the heating effects which have been observed. No reliable measurements have yet been made, nor are any likely to be made, owing to inability to measure the small interval occupied by a lightning flash. The writer considers it probable that the current value is extremely variable, reaching into the thousands of amperes as an upper limit. Discussing the commercial development of lightning conductors, he remarks that the well-known exploits of lightning-rod agents in America have had the effect of making the public sceptical regarding the efficiency of any kind or form of conductor. This is probably the chief cause of the extensive use of thick copper rods, and it is found almost impossible to arouse interest in the barbed-wire scheme in the States. Even the insurance companies are loth to grant risks on buildings thus protected. Considering the great number of violent storms and the consequent losses, and the comparative cheapness of barbed wire, the writer finds it a matter for astonishment that America to-day is at a complete standstill regarding lightning protection. In England things are different. Much progress has been made in this direction, and the old style of copper rod is looked upon as a thing of the past. Considerable attention, too, has been devoted in this country to the architectural arrangement of wires, with the result that in many cases they are only visible at very slight distances.

Electrolytic Preparation of Metals of the Cerium Group.—The preparation of metals of the cerium group by electrolytic fusion is described by Messrs. W. Muthmann, H. Hofer, and L. Weiss in a recent paper which we find well abstracted in the current number of the Chemical Society's *Journal*. It appears that the authors employ a jacketed copper crucible which can be cooled with water throughout the electrolysis. The electrodes are carbon rods, the cathode passing through the bottom of the crucible; the temperature is regulated by means of smaller carbon rods, 3mm. in thickness and 23mm. in length, placed between the electric terminals. When a current of 40 amperes and 10 to 12 volts is employed with this apparatus, cryolite is readily melted, and on removing the connecting small carbon rods the electrolysis sets in, the current strength now being 8 to 10 amperes with 60 to 65 volts. Lead chloride is conveniently electrolysed with a current of 30 to 35 amperes and 8 to 10 volts. Anhydrous cerous chloride, mixed with 10 per cent. of a mixture of sodium and potassium chlorides, is electrolysed with a current of 30 to 40 amperes and 12 to 15 volts; the metal isolated contains 99·92 per cent. of cerium. Cerium is only slightly oxidised in dry air; it slowly decomposes water in the cold, but more rapidly on heating. Nitric acid, even when moderately dilute, attacks cerium, yielding a brown hydroxide, H_2CeO_3, a substance which yields the dioxide on heating. Neodymium is obtained when its chloride is electrolysed with a current of 56 amperes and 25 volts; barium chloride is added from time to time because this salt has the property of decreasing the conductivity of the fused mass, and in this way increasing the temperature. Neodymium is a silvery-white metal, whilst cerium has an iron-grey colour. The former metal has the higher melting point, and is the more oxidisable; it decomposes water especially on warming and is attacked by all acids. A mixture of cryolite and one of the oxides of cerium yields on electrolysis an alloy of cerium and aluminium. Cerium carbide, CeC_2, is obtained from the dioxide by electrolysis in the presence of carbon. This substance yields a mixture of acetylene and ethylene when treated with hydrochloric acid.

Australian Telephone Situation.—The Australian Government some time ago appointed a special committee to investigate the telegraph and telephone services of the Commonwealth and recommend improvements. Having concluded their labours this committee have now made a report, in which they recommend the complete reconstruction of the principal telephone systems on modern lines. In Sydney and Melbourne entirely new systems are recommended, including central offices, conduits, cables, wires, and subscribers' stations. The estimate of cost for the reconstruction of Melbourne system alone is £225,186, of which £156,000, or nearly two-thirds, is for conduits, cables, and other line plant. The switchboard is estimated at £30,000, and the subscribers' instruments at £24,000. In their report the committee acknowledge that the proposed expenditure amounts to a large sum, but they declare that it is impossible to carry on the service with the present plant. The only possible solution of the difficulty is to rebuild the entire system with modern plant, which would provide for at least 10,000 subscribers. The committee further recommend an expenditure of £100,000 for rebuilding the telephone system of New South Wales, £88,000 for South Australia, and £45,000 for West Australia. The establishment of a long-distance telephone line between Melbourne and Sydney, about 650 miles, is also advocated. Such a line, it is estimated, would cost £50,000, with an annual maintenance charge of £2,650. This would be more than met by the yearly revenue, which, at a rate of about 7s. a call with 35 messages a day, would come out at about £3,400. For local service the committee advise the adoption of a new scheme of message rates. The tariff at present in force in the Commonwealth is £9 a year for business service in cities, £7 a year in country places, and £5 a year for residence service. The proposed new rates comprise a flat rate and a message charge, the flat rate being based on the number of subscribers to the system, as follows: For 300 free messages the annual rate would be £4. 10s. with 5,000 subscribers, £5 with 20,000 subscribers, and £6 with over 20,000 subscribers. Any calls in excess of 300 up to 1,000 would be charged for at the rate of 1d. a message, from 1,000 up to 5,000 at ½d. a message, and from 5,000 to 20,000 at ·8d. a message.

Direct-Current Armatures with Alternating Current.—In a recent issue of the *Elektrotechnische Zeitschrift*, Messrs. Fleischmann and Orgler contributed a well-illustrated article on the properties of ring armatures which are supplied with single or polyphase currents through the commutator by means of stationary brushes. The authors give a simple explanation of the process in such armatures. They first consider a ring armature which receives single-phase alternating current from two

Digitized by Google

diametrically opposite brushes, the armature being fixed and the brushes revolving synchronously—*i.e.*, with the same speed as the vector of the current. They show that the E.M.F. induced in the windings, and therefore also the reactance of the ring, is entirely independent of the speed of rotation of the brushes. The magnetic flux varies at all points of the ring with the double frequency of the applied alternating current, the flux waves being pulsating waves; the variation of the flux all over the armature during a complete period is given in a series of diagrams. The authors next consider the same ring armature when it is supplied with two-phase alternating currents through two pairs of brushes displaced in space by 90deg. When the brushes rotate synchronously, the flux has a constant value at each point of the ring, and the reactance of the ring is zero. If the brushes are fixed and the armature rotate synchronously, while being supplied with two-phase alternating currents, then we have a field fixed in the iron and revolving in the space with the speed of the armature. It is thus seen that to supply two-phase currents through a commutator here has the same effect as is obtained with the rotating field of a synchronous motor when direct current is applied by means of slip rings. If such an armature is brought to synchronism in a bipolar revolving field produced by two-phase alternating currents, the armature will run as a synchronous motor, after the alternating-current excitation has been started. By moving the brushes it is possible to vary the relative positions of the stator and rotor poles. If, according to Heyland's method, the commutator segments are connected together by larger non-inductive resistances, the armature will revolve in a revolving field by itself. But it is doubtful whether—especially when loaded—it will approximate synchronism sufficiently to reach synchronism and run as synchronous motor when the excitation has been started.

Ions from Hot Platinum Wires.—The current number of the *Physical Review* has a long article by Mr. C. D. Child describing some investigations he has been making on the velocity of ions from hot platinum wires. The fact that the discharge from a positive platinum wire is greater than from a negative one led the writer to suspect that the positive ions move more rapidly than the negative ones, and for this reason, if for no other, the subject is worthy of attention. His conclusions on this matter may be summarised as follows: The discharge from a hot platinum wire at first decreases and then slowly increases. He observed that the positive discharge commenced a little below the temperature of red heat, increased at first rapidly as the temperature was at first increased, remained nearly constant through quite a range of temperature, and finally decreased somewhat. The negative discharge began at nearly the same temperature as that at which the positive began to decrease. It never became as large as the positive. Both positive and negative discharge increased rapidly as the potential difference between the wire and cylinder was increased. Four methods were used for comparing the velocity of the positive and negative ions. One of these compares the average velocity of one with that of the other. This showed the velocity of the positive to be the greater. Two methods compare the velocities of the most rapidly moving of the positive ions with the most rapidly moving negative. Both of these show the positive ions to have the greater velocity. One compared the slowest of the positive with the slowest of the negative. This showed that at the lowest temperatures the slowest of the positive ions have a much greater velocity than the slowest of the negative, but at higher temperatures a slower class of ions is produced, and the comparison of these with the slowest negative ions gave no definite results. It was also found that at a certain temperature ionisation is produced in the gas about the wire to greater than molecular distances. This is nearly the same temperature as that at which the negative discharge commences, as that at which the positive discharge materially decreases, and as that at which the very slowly moving positive ions commence to appear. Experiments on a wire enclosed in a glass tube indicate the presence in the tube of particles which diminish very greatly the velocity of the ions. The "emanation" appears to load the ions, and thus to diminish their velocity both when they are within an enclosed tube and when they are in an enclosed space. Thus the particles driven off from a hot wire do not appear to aid in the discharge, but, to materially check it. The writer, however, reserves further discussion of this question for another article.

High-Speed Electric Railways.—A paper by Mr. G. W. Meyer on the electrical operation of long-distance, high speed railways is abstracted in the current number of the *Electrical World*. At the outset it is stated that only pure three-phase traction is to be considered, and after some general discussion the author goes on to compare the relative advantages of the two following three-phase systems, the first, with transformer sub-stations distributed along the line, the second, with transformers on the motor-cars, the three-phase currents being supplied to the motor-cars at full voltage. The second system requires heavier motorcars than the first. He assumes a motorcar, with seats for 90 persons, to run at a normal speed of 180 km., and at a maximum speed of 200 km. per hour. For the first system the weight of a car with 12 wheels is 110 tons, hence the pressure on a wheel is 9·2 tons. For the second system the weight of a car is 145 tons, the pressure on a wheel 12 tons. The power required for a motorcar in the first system is 1,420 km., in the second system 2,000 km. He refers to the experience gained in very high-tension transmission in California, and believes that for traction also the tendency will be to use very high voltage, which could not well be transformed down by transformers placed on the train. For all these reasons he prefers the first system, with transformer sub-stations along the line, to the second system, with transformers on the trains. The author next discusses a project for an electric high-speed railroad from New York to Chicago, the distance being about 1,600 km., the present trains taking 23 hours. For the electric road he assumes three stations—at Philadelphia, Pittsburg, and Fort Wayne; he assumes a normal speed of 180 km., and a maximum speed of 200 km.; trains running at intervals of half an hour from both terminals, the total distance being passed through in nine hours. With the first system 100,000 h.p. are required, with the second 130,000 h.p. The essential advantage of the first system is that only very few generating stations are required, two or even one being sufficient; the one power house he suggests placing at Niagara Falls with 10 alternators, each of 10,000 h.p., generating three-phase currents at 11,000 to 12,000 volts, which are transformed up to 75,000 volts; he suggests placing 40 transformer sub-stations along the line each of a normal capacity of 2,400 kw. and a maximum capacity of 4,000 kw.; there the voltage is lowered to 6,000 volts; each sub-station has to supply distances of 40 km. length. On the other hand, with the second system, in which the transmitted currents are directly supplied to the motor car and transformed in it by transformers, he thinks it would not be possible to run a higher transmission voltage than 20,000. This would require 10 generating stations distributed along the line, each supplying a portion of the line of 160 km. He thinks the first system is to be preferred.

CAMPS BAY, CAPE TOWN, AND SEA POINT TRAMWAYS.

Among the important Colonial tramway systems, that of the Camps Bay and Cape Town ranks high. This system, as it exists to-day, is a natural extension of the previously existing Cape Town line, although the Camps Bay section is owned by a separate financial organisation. The construction of this tramway would have presented numerous difficulties under ordinary circumstances, but it will be admitted that these were considerably enhanced when it is remembered that the whole of the work was carried out during the progress of the Boer War. Not only did the course of the war prevent easy shipping facilities, but serious trouble arose from the difficulty of obtaining adequate labour. Yet in spite of these drawbacks the tramway system, comprising nine miles of difficult track work, has been completed without any serious delay. The whole of the materials for the system were supplied and erected by Messrs. Dick, Kerr, and Co., Limited, whose experience in the construction of foreign tramways has been unique as far as an English company is concerned. The same firm, it may be remembered, successfully completed the Barcelona and Madrid tramways, and the progress of this contract, curiously enough, was to some extent interfered with by the progress of the American-Spanish War. Another important Colonial tramway system which has been recently constructed by the same firm is that of the Calcutta tramways. To return, however, to the Camps Bay tramway, it may be stated that the construction has been carried out under special Act of Parliament.

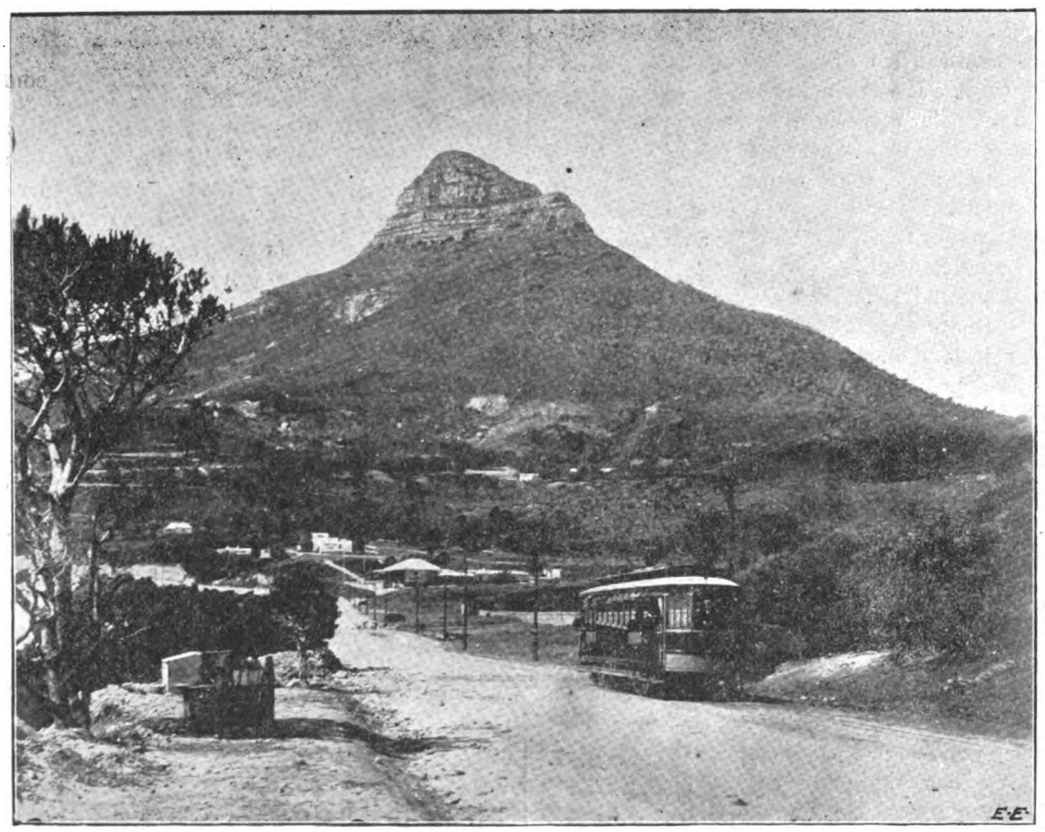

FIG. 1.—Typical View of the Camps Bay Tramways, Cape Town.

Commencing at the Round Church, Sea Point, on the south-west of Cape Town, where connection is made with the Cape tramway, the line commences on an easy ascent, but though gradual it has reached at the end of the first mile an altitude of nearly 300ft., and grades of 1 in 12, or 8·33 per cent, have been encountered. Continuing southward, Upper Clifton is reached, and at this point a magnificent view is obtained of Camps Bay, and the range of mountains—to wit, the Twelve Apostles—stand out clear and distinct. Continuing in a scarcely perceptible descent, the line passes the Old Toll House, and at Camps Bay the track leaves the roadway and continues its course over land purchased by the company. Some three-quarters of a mile distant stands the power-house. After passing the power-house the tramway leaves the existing roadway, and is laid over the private estate of a local land company; following a new roadway, which has recently been made for the purpose, the most southerly point of the tramway is reached at Oudekraal. Here the line diverges in a north-easterly direction, and after encountering the heaviest grades of the system the highest altitude is reached at Kloof Nek. At this point, some 800ft. above sea-level, there is obtained one of the finest views in the Colony. To the south the rugged scenery of Camps Bay and Oudekraal, to the north Cape Town and its world-famed Table Bay, while dimly in the distance lie the Blue Berg Mountains, the Lion's Head and Table Mountain being on either hand.

As affording some indication of the difficulties of construction, it may be observed that the average grade from Kloof Nek to the terminus at Burnside-road—a distance of little more than 1¼ miles—is slightly steeper than 1 in 12. Severe though this may be, it is exceeded in other places, where grades of 1 in 9 are encountered for short distances. The distance from the Round Church at Sea Point is, roughly, seven miles From the foregoing description it is clear that the laying of the permanent way involved more than the usual difficulties. It called for not only a considerable length of new roadway, but more than 75 per cent. of the existing roads had to be widened and graded. Though blasting operations on a large scale were necessary, they provided the compensating advantages of much excellent stone for concrete and road metalling; moreover, the decomposed granite proved a suitable material for surfacing the roadways. Besides making provision for carrying off the heavy rains by means of capacious drains and culverts, massive retaining walls had to be constructed, consisting of dry stonework laid in courses. In places these were of exceptional strength, measuring from 6ft. to 10ft. thick at the base, and from 20ft. to 25ft. in height, crossing the deep sluits of watercourses on the estate.

The gauge of the tramway is 4ft. 8½in., and is thus uniform with the Cape Town tramways, over which system running powers have been obtained. The rails are of girder section, weighing 90lb. to the yard; they are laid

Digitized by Google

on a concrete foundation, a strip of concrete 6in. deep and 18in. wide, composed of 5 to 1 Portland cement, being laid under each rail. Karri wood paving has been laid for a width of 1ft. 10in. on each side of the track, and a 9in. toothing course along the inner side of each rail. The rail joints are each bonded with two $^6/_0$ S.W.G. "Neptune" rail bonds. Special cast-steel points 8ft. 8in. long have been used.

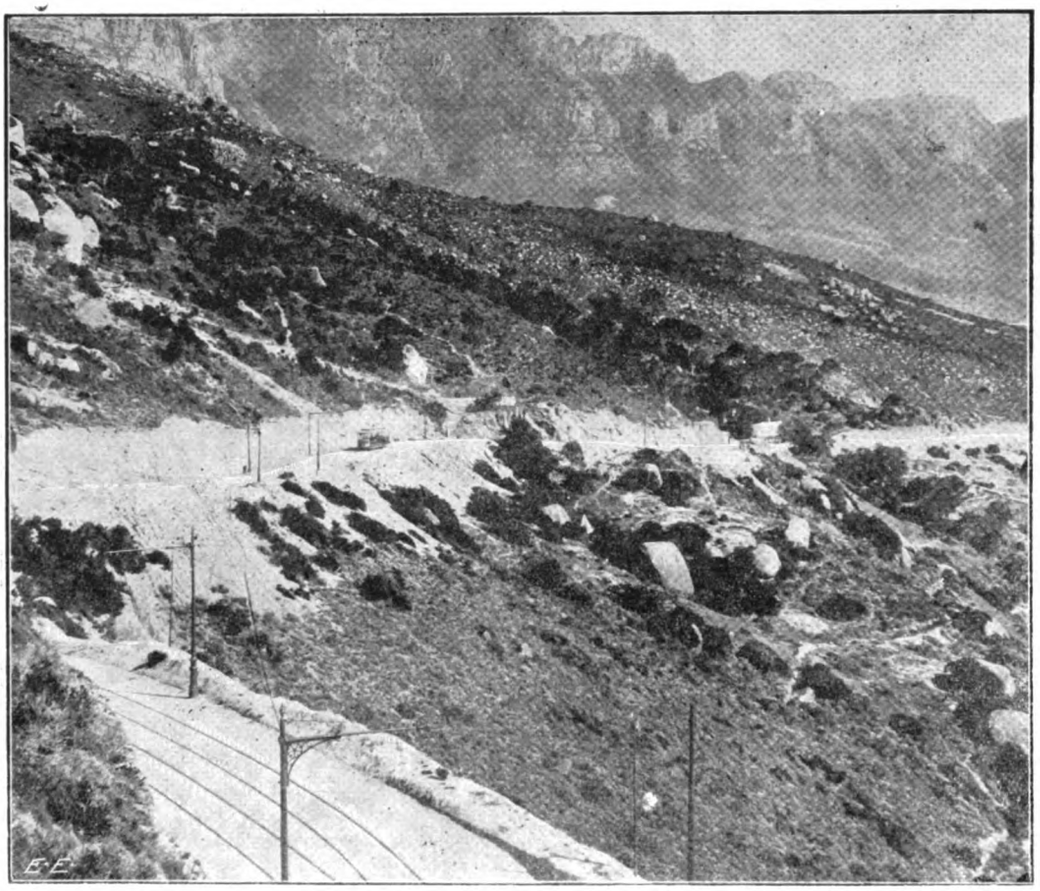

FIG. 2.—View of the Heavy Grades on the Line.

The side-wire system of overhead equipment has been adopted (Fig. 1), the trolley wire, No. 0 B.W.G., being carried at a height of 18ft. 6in. above the rail level. The poles are of mild steel, tapering from 7in. at the base to

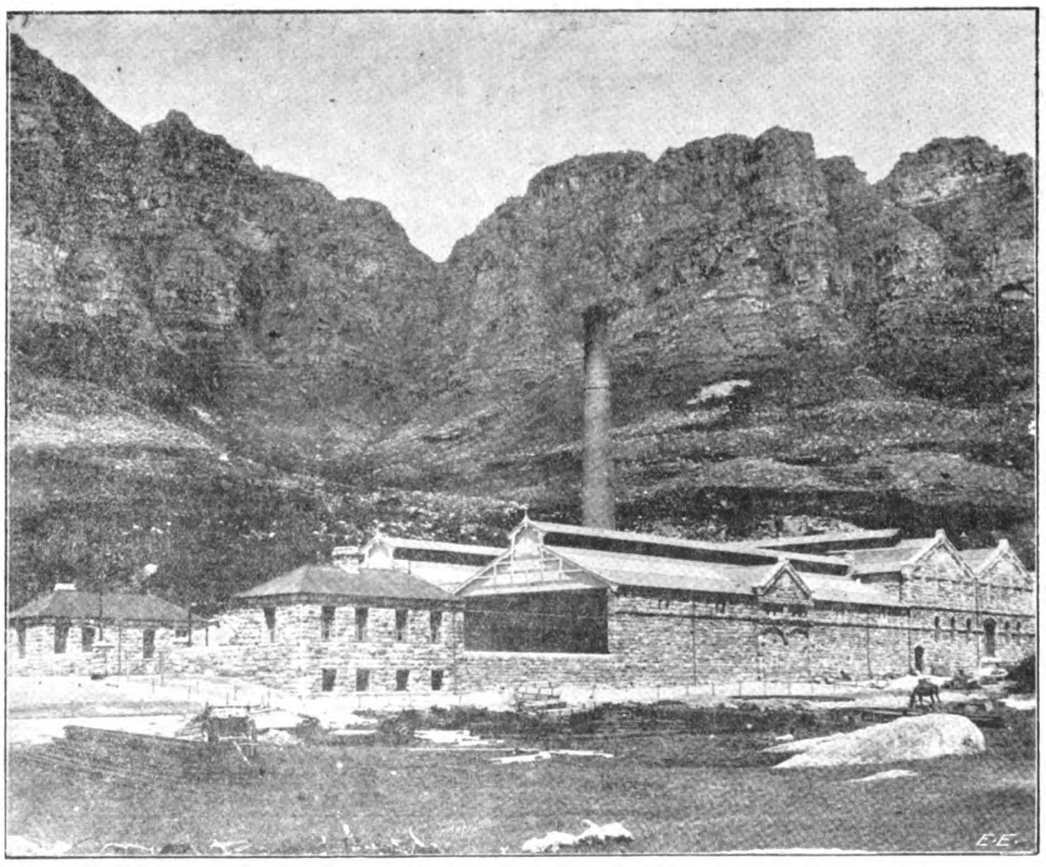

FIG. 3. The Power House of the Camps Bay Tramways, Cape Town.

Digitized by Google

3½in. diameter at the top, and are furnished with ornamental base castings, finials, and brackets. The arms vary in length from 6ft. 6in. to 15ft., according to the width of the road, the average distance of the farthest trolley wire from the centre of the track being 10ft. Owing to the tortuous character of the route, it has been found necessary to run the trolley wire partly on one side of the road and partly on the other to allow of the poles being fixed in the most suitable positions. As many of the curves are of very sharp radii, it will be readily understood that the wiring of these required considerable care to avoid the use of a large number of poles and the angles of the trolley wire being too acute. As will be seen from the diagram map, it is probably one of the most tortuous and heavily-graded systems equipped on the overhead system.

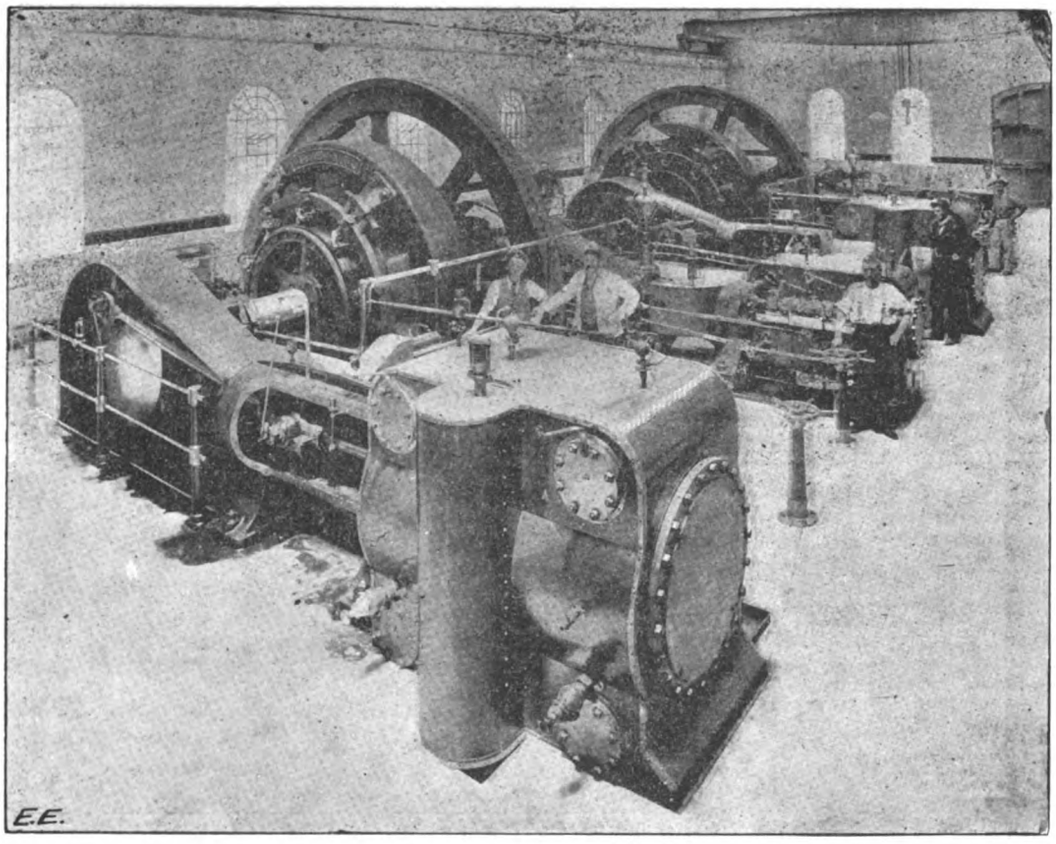

FIG. 4.—The Engine Room with Yates and Thom Engines coupled to English Electric Manufacturing Company's Dynamos.

The generating station and car-shed is situate at Camps Bay, almost at the southern extremity of the system. This site was the most suitable, owing to its proximity to the sea, from whence water is drawn for condensing purposes. Another reason lay in the fact that a continuous supply of fresh water for boiler feed purposes is obtainable from a spring, a small stream flowing therefrom

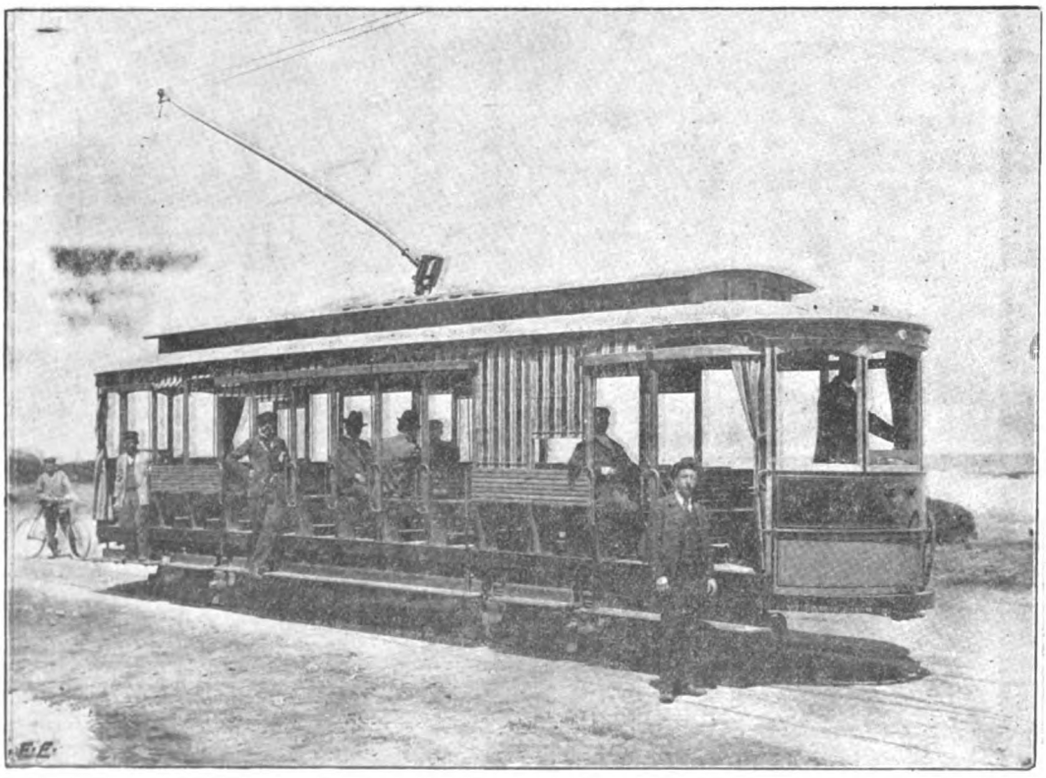

FIG. 5.—One of the Tramcars made by the Electric Tramway Carriage Works.

Digitized by Google

down Table Mountain. The position is fairly central, being near the apex of a triangle formed by the two branches of the route. The engine-room is 94ft. by 42ft., and consists of two floors and a condenser pit. An overhead travelling crane arranged for hand power and capable of lifting 10 tons runs the whole length of the engine-room, and has a lift of 16ft. The boiler-house is 94ft. long by 43ft. 5in. wide. The car-shed, which is also part of the same buildings, is 136ft. long by 94ft. wide, with eight lines of track, four of which have pits running their entire length. At the entrance to the car-shed are offices, mess-room, and stores.

The generating plant (Fig. 4) consists of two direct-coupled 400-kw. sets. The engines, constructed by Yates and Thom, are of the cross compound type, developing 720 b.h.p. with a steam pressure of 150lb. at the cylinders when running at 90 revolutions per minnte. The main shafts are 19in. diameter, and on these the generators and flywheels are keyed. The latter are 18in. diameter, and weigh about 24 tons. The cylinders are fitted with Corliss automatic valve gear. The generators were built at the works of the English Electric Manufacturing Company, Limited, Preston, and were subjected to severe tests by the engineers of the company, Messrs. Alfred Dickinson and Co., Birmingham, who were highly satisfied with the way in which their specification had been met. The output of each of the machines is 400 kw. at 550 volts; they are compound wound, and are in accordance with the standard practice adopted at Preston, and similar to those which Messrs. Dick, Kerr, and Co. have supplied to many tramway and lighting authorities in the United Kingdom. The chief features of these generators comprise the use of a high-permeability cast-iron magnet frame, into which are cast laminated steel pole-pieces. The armature is built up on a special form of spider, in which the sections of the rim are unconnected, thus avoiding shrinkage strains. The core is built up of steel laminations, spacing laminations being inserted to form ventilating ducts for cooling the interior of the core and the windings. The armature coils are laid in open slots on the periphery, and are interchangeable. The commutator is carried on its own ring, which is mounted on an extended hub of the armature spider. The commutator bars are of hard-drawn copper, and are firmly clamped by means of steel end rings Equalising rings are attached to the commutator and equalise any slight variations in the magnetic reluctance of the various magnetic circuits, thus checking the slightest tendency to spark.

The switchboard consists of nine panels, of which three are generator panels, three feeder panels, one station panel, one lighting panel, and one leakage panel. Two of the generator panels only are in use, the other being a spare panel. Each is fitted with a positive and negative quick-breaking switch, capable of carrying 1,000 amperes, a magnetic circuit breaker, and an ammeter reading from zero to 1,200 amperes. Two of the feeder panels are in use, the other being a spare. Each is fitted with an automatic circuit of the same type as those used on the generator panels, an ammeter reading up to 500 amperes, and a quick-break switch for connecting feeder to 'bus bar. The main station panel is fitted with a main ammeter reading up to 3,000 amperes, on which the total output of the station is constantly shown, and a recording wattmeter. It is also fitted with a recording voltmeter, with a working pressure of 550 volts. The leakage panel contains all the instruments necessary for testing for leakage, etc. The lighting panel is arranged for six 50-ampere double-pole circuit switches, with fuses and throw-over switches.

In the condenser pit are two surface condensers, with combined air and circulating pumps. These are of the Admiralty type, and are specially devised for using sea-water. The sea-water is supplied to the condensers by means of large cast-iron pipes, which are carried well out beyond low-water mark. To avoid the danger of seaweed being drawn up into the condensers, the suction pipe has been intercepted on the shore by a sump built in concrete carried well down below low-water level, which is easily kept clear. In the boiler-house are two water-tube boilers, each with a heating surface of 3,654 square feet, and capable of evaporating 12,000lb. of water per hour under normal conditions. Each boiler is fitted with a dead-weight safety valve and a spring valve set to blow off at 160lb. pressure. The collars are fed by means of two compound non-condensing duplex feed pumps, working at a pressure of 160lb., and capable of delivering 24,000lb. of water per hour against a boiler pressure of 160lb. Before being pumped into the boilers the feed water is passed through a fuel economiser, containing 288 pipes, fixed in the main flue. The chimney stack is 125ft. in height, and 5ft. inside diameter at the top. The works are equipped with the necessary machine tools for the purpose of carrying out the repairs, and comprise a large screw-cutting gap lathe, wheel lathe, wheel press, drilling machines, grindstone, smiths' hearth and fan, the whole being driven by an electric motor.

The feeders are lead covered and insulated with paper and vulcanised rubber. They are laid in cast-iron troughs 18in. below the surface and surrounded with bitumen. The main cables are laid in half-mile sections, and at the junction of each section a feeder pillar is placed in which the cables are connected to a 'bus bar, and from thence to the trolley wires in the usual manner. It is natural that climatic conditions should to a great extent determine the type of cars, and it will be seen on reference to the illustrations that variation has been necessary in the case of Cape Town. The cars (Fig. 5) are single-deck bogie type, part are what are known as gridiron open cars, and part are of the combined type. The former have a seating capacity of 65 passengers, and the latter of 54. The length of car is 40ft.; width, 7ft. 6in.; and height inside, 8ft. They were built for Messrs. Dick, Kerr, and Co., Limited, by the Electric Tramway Carriage Works, Preston, and shipped to Cape Town completely finished, the only work to be done before they could commence to run being to mount them on the trucks, connect the wiring, and fix the trolley poles. In passing, it may be observed that so popular has Camps Bay already become that the company anticipate that the present equipment of cars will shortly be found too few to cope with the traffic. The car bodies are mounted on trucks of the bogie type, each truck carrying two motors, one on each axle. Departing somewhat from the usual lines, the equipment of the cars comprises four motors, each of 25 b.h.p., so that each car is capable of developing 100 b.h,p. There is hardly any question that four motor equipments with long cars are imperative where grades are heavy, and in the case of Camps Bay the gradients are unusually heavy. Not only, however, is a proper distribution of power necessary, but the question of braking and retardation is of prime importance. The brakes, therefore, on these cars have received very careful consideration, three brakes having been fitted—viz., a hand-brake, with a brake block on each of the eight bogie wheels; an air-brake, acting in conjunction with the hand-brake; and an auxiliary slipper brake. In addition to these it is also possible, by throwing over the reversing switch, to convert the motors into generators, thus enabling them to act as a powerful emergency brake. The cars are operated from either end by means of special controller designed for four-motor equipments.

It may be stated that Messrs. Dick, Kerr, and Co., Limited, carried out the work to the specification of Messrs. Alfred Dickinson and Co.

ALDERSHOT ELECTRICITY WORKS.

These works, which were inaugurated last week by Lady Hildyard, have been carried out under the supervision of Mr. Nelson F. Dennis, the surveyor of the Urban District Council. When electric lighting was first spoken of in Aldershot, it was hoped that the town would get the contract for supplying electricity either in bulk or in detail to the various Army buildings situated in and around the town. At that time we believe a consulting engineer was called in, and gave a report as to the establishment of a station which would be capable of supplying all the camps as well as the town. The decision of the military authorities to erect their own electric supply station, however, put a new complexion on the matter, and the scheme was

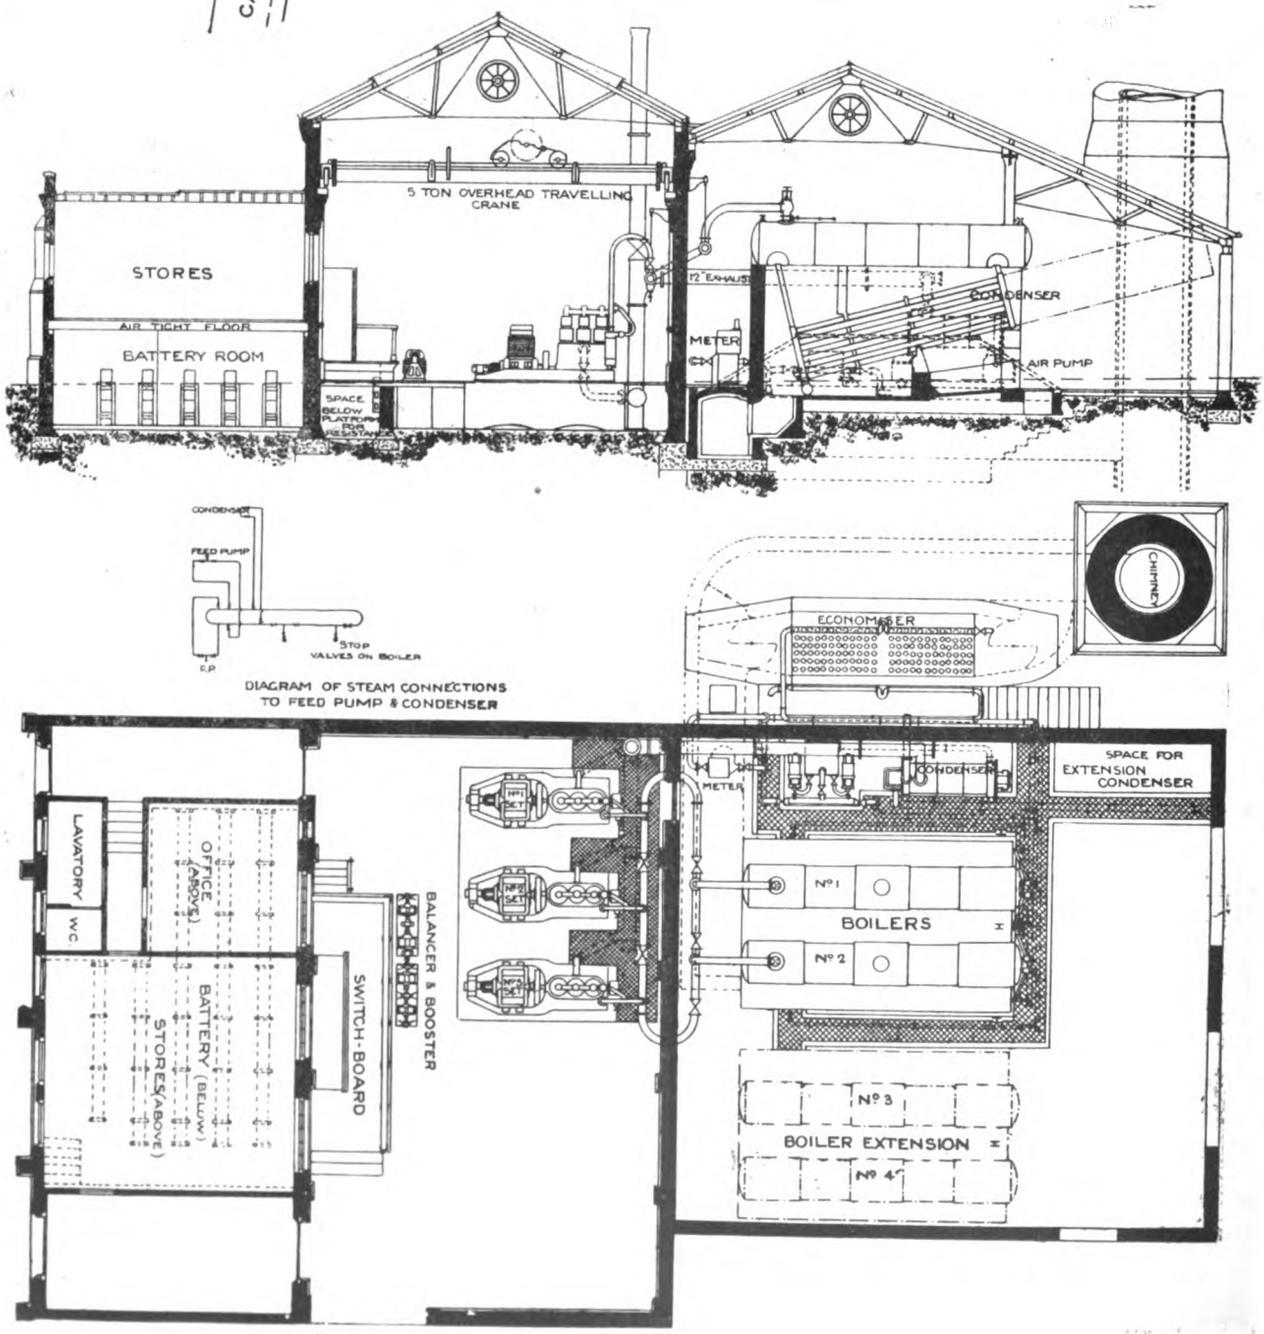
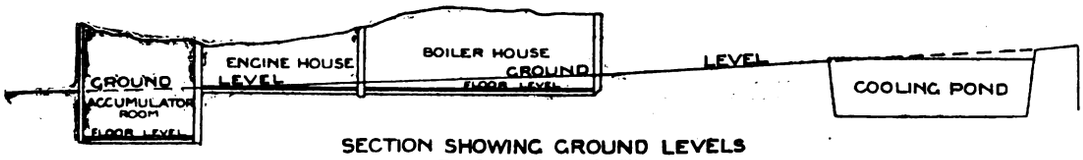


FIGS. 2 AND 3. – Plan and Sectional Elevation of the Aldershot Electricity Works.

Digitized by Google

not carried out. A committee of the Town Council was afterwards appointed to go round and inspect electricity works in some nine or ten towns in England. Mr. Nelson F. Dennis, the surveyor, accompanied this deputation, and had a considerable hand in the drawing up of the report. The decision arrived at was that tenders should be invited from contractors who were able and willing to supply everything required for the scheme with the exception of the buildings. The details were as a rule left to the parties tendering, but the output required from the plant and the size of the mains was, of course, the same in each case. The result of the invitation to tender showed a remarkable closeness with regard to the amount of the lower tenders, and the work was placed in the hands of Messrs. Thomas Parker, Limited, of Wolverhampton. We may say here that this reversion to the older method of employing only one main contractor, and making him responsible for the whole of the work, has in Aldershot produced excellent results. Messrs. Parker, Limited, selected for their sub-contractors firms of the highest order, and the result is that good harmony exists between the various items making up the complete system.

The works are situated in one corner of a large piece of land which has been acquired by the Urban District Council. In Fig. 1 we give a block plan of that portion of the site which has been allotted to the electricity department. On the larger piece of ground, not shown in this illustration, it is proposed to erect large municipal buildings, and the vacant space behind will be laid out as pleasure grounds. The buildings were designed throughout by Mr. Dennis, and are exceedingly well arranged for the purpose they serve. They consist, as can be seen from the general plan and elevation (Figs. 2 and 3), of an engine and boiler room, with offices adjoining. Under these offices is arranged the accumulator-room, which is most conveniently situated as regards the switchboard, so that the length of the connecting cables is small. The buildings now erected will contain a considerable amount of extension in plant without any alteration, as will be gathered by an inspection of the plan (Fig. 2). When this spare space has been occupied the building can be enlarged. In connection with the engines, which are working condensing from the very first, a cooling pond has been arranged. The position of this can be seen on the block plan (Fig. 1), while Fig. 4 shows a cross-section through the cooling pond and the building, and Fig. 5 gives the details of the pond itself. The water for condensing purposes is collected from the rain-water sewers of the high land lying behind the works. From the records of rainfall in the district, Mr. Dennis expects to keep this pond always full, and any rain which comes in will, of course, tend to change the water in the pond itself. When full this pond contains some 5ft. of water. Its other dimensions are 71ft. long by 39ft 6in. broad. The circulating water for the condensers is taken from the bottom of one corner of the pond and returned into it at the opposite corner. The chimney shaft (Fig. 6) is 110ft. high, and the flue in passing to it goes through a Green's economiser of 144 tubes. The scraper of this economiser is driven by a small Parker motor.



SECTION SHOWING GROUND LEVELS

FIG. 4.—Section of the Site.

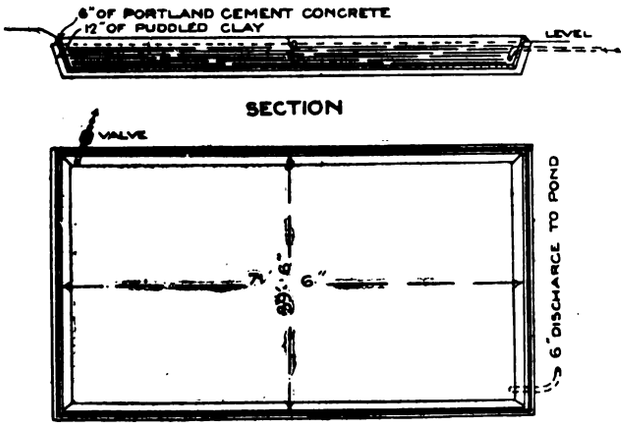


FIG. 5.—Details of Cooling Pond.

The equipment of these works consists of two Babcock-Wilcox boilers, each of which is capable of supplying two of the main generating sets at full load. These three steam dynamos, seen in Figs. 2 and 3, are Willans-Parker combinations. They consist of Willans engines of the 3 G type directly coupled to a Parker two-pole dynamo, capable of giving 80 kw. as a normal load, or 90 kw. on emergency. These dynamos, which can easily be used for traction purposes, if so required in the future, can give any voltage from 420 up to well over 500 volts

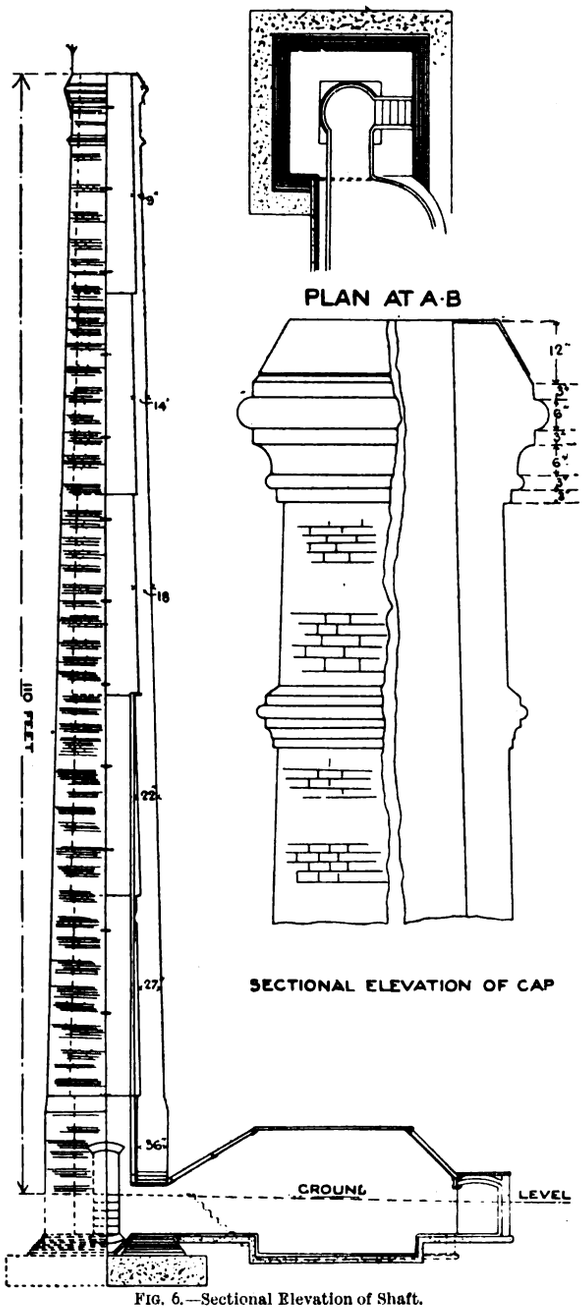

FIG. 6.—Sectional Elevation of Shaft.

Digitized by Google

as shunt machines. The armatures are wound on the Eickemeyer system, and the commutators have copper bars, and not gunmetal. The steam-pipes are arranged on the ring system, as will be gathered from the illustrations. The other electrical plant consists of a balancer and booster combination, which is placed by the switchboard platform. The boosters are, of course, used to charge the accumulators, while the balancers are capable of dealing with about 75 amperes of out-of-balance current on either side of the three-wire system. The switchboard is of the usual type as regards connections, but the details of the board itself show considerable improvements over the average switchboard for three-wire working. In the first place, the whole of the regulating apparatus for these two batteries of accumulators and for the field circuits of the dynamos are arranged on the middle wire, so that they are practically at earth potential. Of course, when regulating, there may be a few volts above or below this potential, but the difference is small. Kelvin measuring instruments are used throughout. The automatic switches in the dynamo circuits are of Messrs. Parkers, Limited, own make, and the release is effected by the interaction between a shunt and series coil, so that the switch operates at either no load or overload as the case may be. Another detail, for which we believe Mr. O. F. Francis is personally responsible, is the use of some winged thumb nuts for clamping all the fuses. These can be easily turned by hand, and can be more readily operated than an hexagonal nut requiring a spanner. There is also with the spanner a considerable risk of making connections with adjacent metal work, which risk is avoided with the present construction. We may mention here that Mr. Francis has superintended the whole of the works for Messrs. Parker, Limited, and that he will be responsible for the running of the station for the first six months. He was selected for the work with an idea that he would afterwards take charge of the plant as the borough electrical engineer, and from the care he has taken in the carrying out of the detail arrangements the choice could not be improved upon. The switchboard as at present arranged provides for three feeder circuits, three main dynamos, two batteries of accumulators, and the balancers and boosters. On another board at one end of the engine-room Mr. Francis has grouped together all the switch and fuse gear, which is so often scattered throughout an electric lighting station. On this board the instrument for recording the earth return current is placed, and also the switches and fuses for the lighting and power circuits in the building. A throw-over switch is provided, by which this load can be transferred from the one side of the system to the other, in order to compensate for any out-of-balance current on the mains.

The accumulators are of the D.P. type, of which 240 cells, each of 300 ampere-hour capacity, are provided and grouped in two main batteries. Twelve more cells of the same size have also been erected for use in connection with meter testing and as hospital cells. These batteries, which are of the D.P. Company's central-station type, can give a discharge of 100 amperes for one hour if so required. The current going into and out of each of the main batteries is registered on Chamberlain and Hookham meters. Two meters, one of which will run in each direction, are connected in each battery circuit. The reversal of the direction of rotation of the motors in these meters is prevented by means of small pawls acting on one-toothed ratchet wheels. By making the meter, which runs when the batteries are being charged, read 10 per cent. slow, the batteries should be kept in order if the two meters give identical reading.

The whole of the mains in the town were supplied and laid by the Callender Cable and Construction Company. The general arrangement of these mains can be seen in Fig. 7, in which the feeding points are indicated by a star

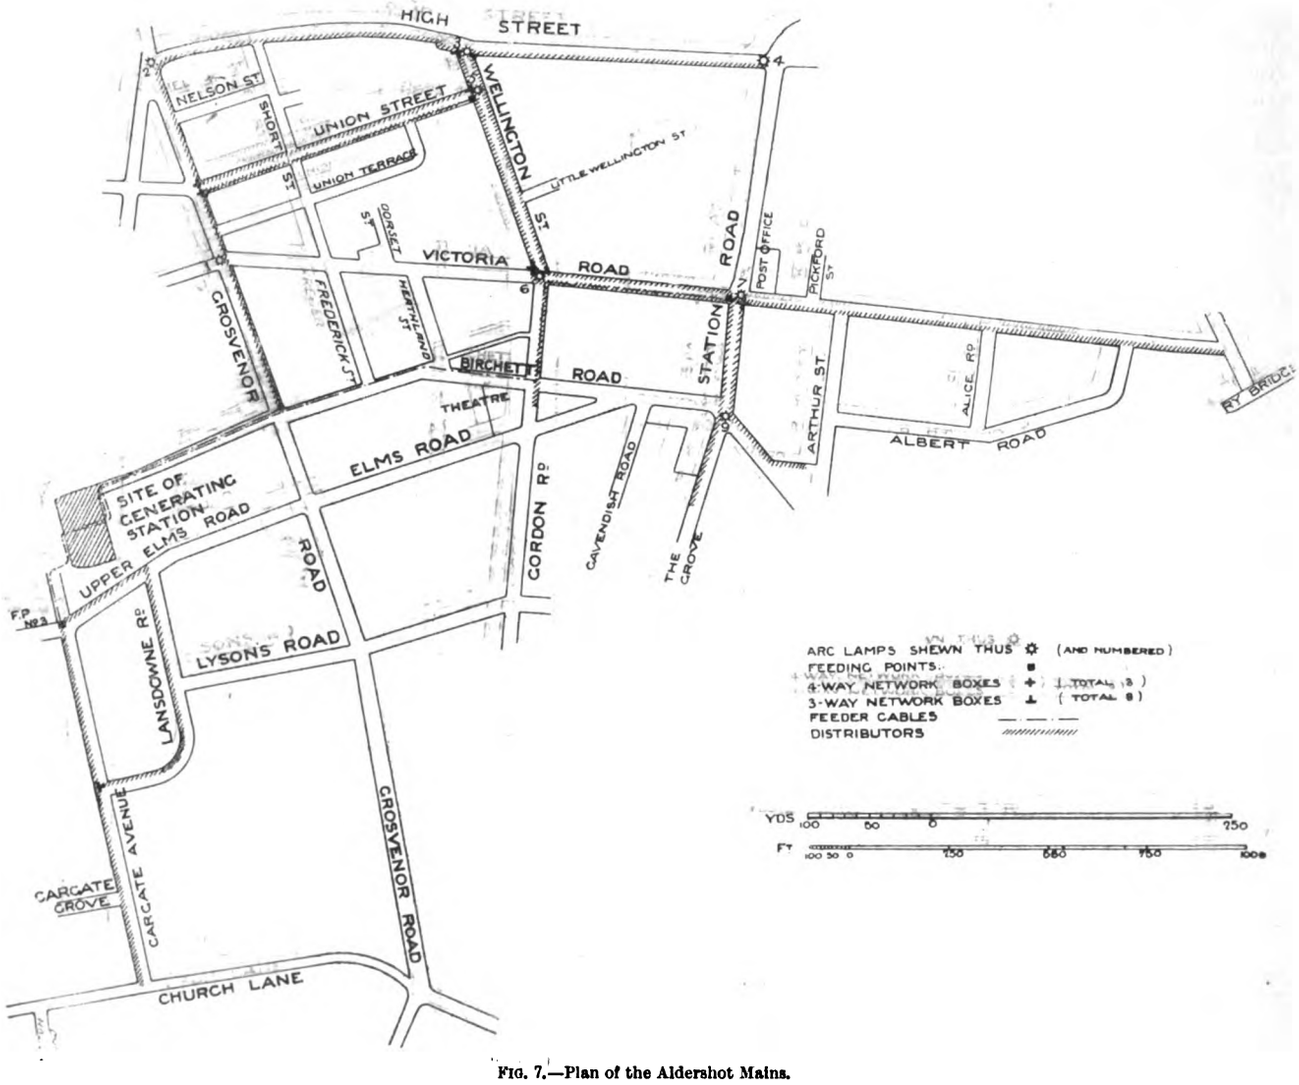

FIG. 7.—Plan of the Aldershot Mains.

Digitized by Google

with a white centre. The shading along the sides of the streets indicate where distributing cables are laid. The section of these distributing cables is, as a rule, ·1, ·06, and ·1 for the more important streets, and three conductors of ·06 in other cases. The No. 1 feeder, which supplies at the junction of Union-street and Wellington-street, has a section of ·4 of a square inch, as has also No. 2 feeder, which supplies at the corner of Station-road and Victoria-road. Besides these distributors and feeders, two arc lighting circuits have been laid from the station. At present only four arc lamps are supplied on each circuit, but they can easily be extended into eight or nine arc lamps per circuit. The whole of the cables are insulated on the Callender's system with vulcanised bitumen, and are laid on the solid system in wooden troughs with tile covers. Owing to the excellent footpaths of cement concrete used at Aldershot, it was decided to lay these cables in the roadway, just beyond the channelling, as this has kept down both the damage to the footpaths and the cost of making good. The arc lamps for the street-lighting, which were also supplied by Messrs. Callenders, are of the Oliver type. The excavations for the mains and the making good of the trenches were carried out by the surveyor.

The works are to run for six months by Messrs. Parker for a sum equal to 3¾d. per unit generated, but the Council guarantee a consumption of 50,000 units. Already nearly 50 consumers have been obtained, with over 2,000 8-c.p. lamps, exclusive of the public lighting. The charges are to be made on the Wright system, with 6d. per unit for the first hour's daily use of the maximum demand and 4d. per unit for all electrical energy in excess of this. For power the charges will be 3d. per unit for the first hour and 2d. per unit afterwards. We have to thank Mr. Nelson F. Dennis and Mr. O. F. Francis, the resident engineer, for their assistance in collecting the above information, and for the loan of the drawings from which the illustrations were prepared.

FORMERS AND FORMER-WINDING.

BY F. W. DAVIES.

(Continued from page 695.)

III. Formers for Ring Armature Coils.

Ring armatures are not used to so great an extent as they were formerly, except for machines for the higher voltages; such, for instance, as those for pressures of over 500 volts. For the ring type of armature former-wound coils are not often used, although for drum armatures hand-winding is the exception and former-winding the rule. Former-winding is only practicable for *wire-wound* ring armatures when the plain type of armature core is used. *Bar winding*, however, can be used whether the armature core be of the plain, toothed, or iron-clad type. In fact, as will easily be understood, the ring armature does not lend itself very readily to former-winding, especially when the coils are wire-wound. Nevertheless, for the sake of completeness, a brief mention of what has been done in this line will be made. The advantages which have been enumerated as accruing from the use of former-winding refer more particularly to drum-wound armatures, and are only partially realised in the case of ring-wound armatures. Not only is this so, but former-winding for wire-wound ring armatures is more expensive in most cases than hand-winding. Its use, therefore, is to be recommended only for very small machines designed for ordinary voltages, such, for instance, as those small motors developing a fraction of a horse-power, which are usually run off 100 and 200 volt mains. In such machines each armature coil consists of a large number of turns of very fine wire. If the armature is hand-wound, a length of wire sufficient to wind one coil has to be wound upon a winding shuttle, from which it is wound on to the armature core. It is in such a case as this that former-wound coils may be used with some advantage, as then the use of the winding shuttle is dispensed with. The armature core must, of course, be made in two or more sections, otherwise it will not be possible for the coils to be threaded on it. A ring armature core designed for use with former-winding is shown in Fig. 5, in which is also shown one of the segmental stampings of which the core is built. The armature core is made in two halves, which are hinged together by means of a pin passing through the hole marked A. It is shown open, ready to receive the coils. After the coils have been slipped over the ring core the two halves of it are closed up until the two holes, B and B_1, coincide. The two halves of the ring are then locked together by means of a pin, which passes through the holes, B and B_1, when the armature may be mounted on the spider in some suitable manner. The coils for such an armature may conveniently be wound upon a divided block former of similar design to that used

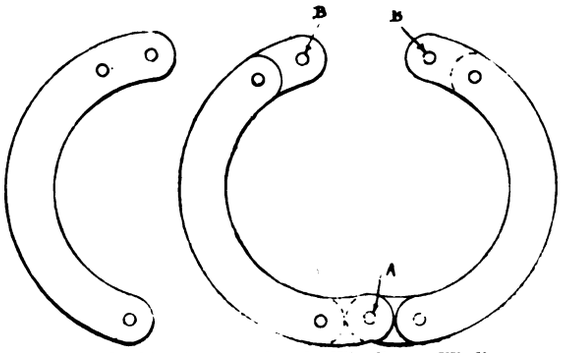

Fig. 5.—Ring Armature Core for Wire Former Winding. (Showing Detail of Segmental Stamping.)

for magnet coils (Fig. 2), but with the flanges inclined to one another at a slight angle, instead of parallel to one another as in the figure. By this means one side of each coil will be made narrower than the other. The coils must be placed on the core so that the wide part comes on the outside of the ring and the narrow part on the inside, on account of the peripheral space being less on the inside of the ring.

Bar winding for ring armatures is simpler than wire winding, as there is usually but one turn per section in a bar-wound armature. As has already been pointed out, every symmetrical bar winding is, strictly speaking, a species of former-winding. On account of the difficulty of bending conductors of large section, it is advisable to use a bar winding, whether the armature be a ring or a drum, when the conductors require to be much larger than ·03 of a square inch. Conductors larger than this, no matter whether solid or stranded, are found to be too unwieldy for wire winding. Bar-wound coils for ring armatures are very simple in construction. They are of practically the same shape as their hand-wound prototypes. In Fig. 6 is

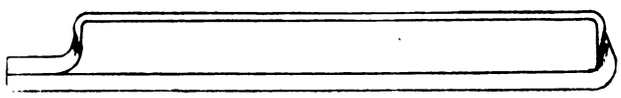

Fig. 6.—Formed Coil for Bar-Wound Ring Armature.

shown a coil for former-wound ring armatures of a type used by Messrs. Crompton and Co. It will be noticed that the conductor is arranged so as to be placed edgewise to the core on the inside of the ring. This is done for the same reason that one limb of a wire-wound coil is made narrower than the other—namely, that the conductors may be packed more closely on the inside of the ring. The coils are sprung over the core, and are then ready for coupling up. As these coils can be obtained from the manufacturers ready formed for assembling on the core, and as they are of exceedingly simple construction withal, it is not necessary to describe a former for them.

An alternative way of making the coils to that shown in Fig. 6 is to have the outside and inside limbs of each coil in separate lengths, which are riveted and soldered together when they have been assembled in their places on the core. This latter method is preferable to the other for very massive and stiff conductors, as it obviates the necessity for springing them open in order to get them on the core.

(To be continued.)

NOTE ON AMERICAN PRACTICE IN DYNAMO DESIGN.

BY T. SQUARE.

The fact that up to the present date almost every generating station of any size in the British Isles has been equipped with American machinery is one which the electrical firms of this country are, at last, beginning to wake up to; and we may hope that before long this unsatisfactory state of affairs will be, to some extent at any rate, remedied. The chief things which have been in favour of the Americans all along are their go-ahead business management, and the fact that, although some of the first examples of electric light and traction were in England, it was in the States that the subject was enthusiastically taken up, and where all the various details have been worked out. In fact, the whole modern system of "multiple unit control" may be said to have been perfected by them alone. At the present day, however, there are several firms in the British Isles, apart from the American firms with English branches, who can turn out most lines of electrical machinery quite as well and as cheaply as the Americans. This is especially true of continuous-current dynamos and motors. But now that the Americans have caught the popular fancy, it is very difficult to get the trade into our own hands again.

One great reason why the Americans have been so successful in the past is due to the fact that all the machines they put in ran fairly well. This can be attributed to the low speeds which they always adopted whenever possible. Almost anyone can design a machine which will run well at low speeds, but it is a matter of extreme difficulty to design machines over 300 kw. or 500 kw. which will run well, especially with regard to commutation, when coupled to a high-speed engine of the Belliss or Willans type. England may be said to be the home of the high-speed engine, and many English dynamo builders have tendered for machines direct coupled to these engines, often with very little previous experience. The usual result is an indifferent running and "sparky" machine, and the next time the customer has an order to place it goes to a foreign firm. The designing of large direct-current generators for high speeds is a difficult task, and where the Americans have attempted it they have in many cases turned out far worse machines than those of the English builders. The fact that C. A. Parsons and Co. have turned out several 300-kw. dynamos direct coupled to their steam-turbines at 3,000 revolutions per minute, is a good proof that English makers are as good as any for high-speed generators.

The output of any continuous-current machine may be said to be limited by one of two things—either heating or commutation. Small machines—say below 26in. diameter of armature—are usually limited by heating, larger machines by commutation. In other words, in a big machine we can increase the load until the sparking at the commutator begins to get troublesome, and still the temperature rise on the core of the armature will only be about 40deg. or 50deg. F., the temperature which is usually stipulated as a maximum being 70deg. F. Some people have the idea that a low temperature rise is an excellent thing under all circumstances, being willing to buy a machine much too large for its work if it will only give a low temperature rise, the idea being, as far as I can make out, that its efficiency must be very good, as there are very few watts being wasted in heating the machine up. This is, of course, quite wrong, as it is well known that a machine only partly loaded may have a lower efficiency than a smaller machine fully loaded. It is, however, a good thing to have a fairly low temperature rise on a machine which is to be used in some confined space where the normal temperature may be often about 90deg. F., as is the case with ship-lighting sets. It is also better to have a little lower maximum permissible temperature rise on a large generator than on a small machine, as the consequences of any damage to insulation resulting from over heating is much more serious. It is not a great matter to have a small 10-h.p. motor shut down for a day or two as a rule, but it may be a very expensive affair to do the same with a large 1,000-kw. generator in a heavily loaded station. Again, temperatures are usually measured on the outside of the armature, but the temperature inside the core is still higher. However, for the same outside temperature of armatures the temperature inside the core of a big machine will be much higher than that of a small machine, owing to the greater distance that the centre of the mass generating heat is from the radiating surface. It is, however, quite safe to work to 65deg. F. rise by thermometer on outside surface up to the largest sizes of machine without damage to the insulation. On small machines we can work to 75deg. to 80deg. F. rise, while in traction motors the rise may go up to 130deg. F. or so.

The time taken by a machine to reach a steady temperature—*i.e.*, to reach its maximum temperature rise—for any given load varies with the size of machine over very wide limits. Thus a small 1-b.h.p. fan motor will probably reach a steady temperature after one hour, whereas a large 1,000-kw. generator may require anything up to 12 hours. Machines up to 500 kw. will, however, have reached their maximum temperature in about six or eight hours, or at least the rise will be very slow, as this figure is usually taken as the duration of a test. The American standard temperature rises were fixed by a committee formed for the purpose, and are as follows:

For armatures: open machines, 65deg. to 75deg. F.; enclosed, 90deg, to 120deg. F.

For fields: 80deg. F., measured by increase of resistance.

For commutators: 75deg. to 90deg. F.

The Americans have been very much ahead of us in combining a good mechanical design with the cheapest possible construction. For instance, the magnet yoke, bed-plate, and bearing pedestals are in small machines usually cast in one. The poles are also cast into the yoke, so that all the machining to be done is to bore out the poles and bearings. Again, most English builders use a spider over the spindle to thread the armature core plates on to, so that if the spindle gets bent or damaged by rough treatment it can be replaced by a new one without pulling the armature to pieces. This is done down to the small 4-b.h.p. or 5-b.h.p. motors. The Americans, on the other hand, prefer to use a rather stiffer spindle, thus allowing for a certain amount of rough usage, and thread their core plates directly on the spindle, thus making a cheaper machine.

Another point where the Americans gain, especially in the manufacture of small motors, is that he turns out such a large number of similar machines at a time. Thus the Crocker-Wheeler Company make:

55-kw. machines	at about	25	at a time.	
20-kw.	„	„	40	„
Smaller	„	„	60	„

Each machine tool is set for doing one particular job, and the workman is kept at that one job alone, so that the cost of production is enormously reduced. The small sizes of motors and dynamos, too, are made only with six or eight standard windings, which are chosen to suit the speeds and voltages usually asked for, and the customer has to take these standard machines unless he is prepared to pay a substantially higher price to have a machine made to his own special requirements, and even then a great many American firms will not take the order, as they have quite enough work to keep them going on the standard types In England in too many cases each little motor is treated on its own merits, so to speak; special armature and field windings are got out and the little fads of the customer or consulting engineer studied as far as ever possible, the result being a machine no better than the American one, but far more costly.

In England nearly all business is done through a consulting engineer, and it is really rather ridiculous when a manufacturer gets an order for, say, a 10-h.p. motor to find a specification enclosed, covering about 20 pages, imposing all sorts of conditions, such as the current density in the armature and field conductors and in the brushes, the number of oil-rings in the bearings, etc.—in fact, practically designing the machine. If the manufacturer has to take

Digitized by Google

the responsibility for the good performance of a machine, he ought to have a free hand in designing it. If, on the other hand, it is to be built to a consulting engineer's design, he should take the responsibility for its performance. In America, the manufacturer is not worried like this; in fact, most small motors are simply sold "over the counter," the makers, of course, guaranteeing their satisfactory performance. In very many cases where an order has been obtained by a foreign firm, they have simply put in their standard machine, and no objections have been raised to the points where it differed from the specification. If this had been done by an English firm the machine would probably never have been accepted.

The magnet yokes of American machines are now made of cast iron in most cases, the only exception being for traction motors or in cases where weight is of importance. The difference in cost between a cast-iron or cast-steel yoke is slightly in favour of the former, as although the steel has a much higher permeability, the cast iron is much cheaper. The section required, and hence the weight, for cast iron is 2 to 2½ times that of steel. Cast iron, however, exercises a great steadying effect on the running of the machine if it is inclined to be unstable at all. This is because any slight change of flux through the yoke produces large eddy currents, which tend to stop any further change. This effect is also produced in many machines by fitting a ring or strip of copper round the poles. A cast-iron yoke of "hog-back" section is also, I think, a much nicer-looking job than the steel yoke with its stiffening flanges. The poles are usually cast solid with the yoke in machines up to about 6 h.p.; above this they are made of laminated steel plates about $\frac{1}{16}$in. thick, and cast into the yoke. The field coils are former-wound, and in many cases simply taped and whipped with string and put in place without any bobbin. They look very well, and work quite satisfactorily. In large compound-wound generators the series coils are only fitted to alternate poles, thus saving a certain amount of complication.

The General Electric Company, however, use round solid poles, and fit separate laminated pole shoes, which are fixed to the pole by countersunk cheeseheaded screws. This reduces the mean length of turn of the field winding, and so effects a saving in copper. Also there is no appreciable loss cause by the non-lamination of the pole, since the eddy loss set up by the teeth in passing is only a "skin" effect, and does not penetrate more than about 1in. Most firms make the flange, where the two halves of the yoke ring are bolted together, on the inside, which greatly improves the look of the machines, also a beading is cast around the top half of the yoke at the joint to prevent the necessity of chipping should the two outside surfaces not butt together nicely when erected. The brush gear is supported from the tail bearing for small machines up to about 26in. diameter of armature, but above this from the yoke ring, which affords a wider and firmer base.

As regards the armature, specially stiff spindles are used on all machines, and armature spiders are used above about 18in. to 25in. diameter of armature, this being about the usual point of transfer from four to six poles, and where owing to the smaller relative flux per pole a smaller core cross-section may be used. The flux densities adopted in American machines are about as follows:

Core	= 13,000 to 18,000	lines	per sq. cm.	
Teeth	= 18,000 to 21,000	,,	,,	
Poles	= 13,000 to 16,000	,,	,,	
Yoke	= 13,000 to 16,000	,,	,,	for cast steel.
	= 6,000 to 8,000	,,	,,	for cast iron.

The armature core plates are punched in one operation complete, to do which very complicated punches and discs have to be used. For large machines, of course, the old slot-by-slot method is still used, except in those cases where the core plate is made up of several segments, when each segment can be made at one operation. The slots are in all cases rectangular, and the windings are held in place by wooden strips or covers, which are slid in two small grooves at the top of the slot, as in Fig. 1. Great attention is paid to the quality of the iron, and the plates are carefully annealed after stamping so as to keep the iron loss as low as possible. This is a most important matter, not so much from the point of view of efficiency as from that of heating. In those machines whose outputs are limited by heating, it is as well to remember that of the total watts got rid of by the armature for a given standard temperature rise at least one-half is iron loss, hence the more we can keep these losses down the more we can increase the output of the machine. The armature should be most efficiently ventilated, so as to increase the permissible watts which can be got rid of. At least 15 per cent. of the total length of core plates is taken up by ventilating spaces, the core plates being held apart by brass distance pieces. These distance pieces are either made separately, and

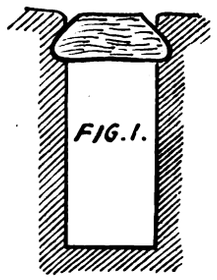

FIG. 1.

fastened in place one by one, or they may be all cast in one and fastened at one or two points only. The latter method is probably the cheapest. The end castings which are used to hold the core plates together, and to support the "end connections" of the armature windings, should be made of cast iron of high specific resistance, so as to prevent any stray field from causing much loss by setting up eddy currents. They should be well ventilated, so as allow of a good flow of air past the end connections of the armature winding. In four or two pole machines, however, it is found that practically the whole of the cross-section of the core is required for the flux, so that in very small machines ventilation has to be given up.

In large generators the spider has a number of radial arms, ranging from 4 to 20 or so, and the segments of the core plates (if the machine is large enough to require its core plates to be in segments) will each be dovetailed into at least two of these arms, as shown in Fig. 2. This exposes the inside of the core freely to ventilation, and the spider arms, together with the brass distance pieces in the ventilating spaces, act as the vanes of a fan in forcing air through the core of the machine. The armature coils, which are all former-wound on machines above about 12in. diameter of armature, are squeezed to shape in steam-heated presses after being wound. In some firms the formers are power-driven, but this has not been found to reduce

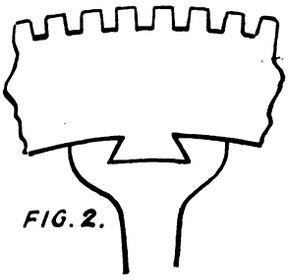

FIG. 2.

expenses. In small machines the armature coils are simply wound in loops and pulled into shape by hand. This is, of course, much cheaper, but it does not make such a nice-looking job, and also tends to bruise the insulation on the wires if they are of at all large section.

The insulation on the armature and in the slots varies very much with different makers. The slot is usually lined with micanite, and the coil limbs in both the top and bottom halves of the slot are held together with india-rubber, or impregnated linen tape, after being insulated with mica cloth or presspahn—*i.e.*, pressed cardboard. Each wire in the half slot is insulated from its neighbour by double cotton covering, braiding, or tape, according to its section. The Stanley Electric Company have got out a method of covering copper wire with boiled linseed oil, which they say is quite as good as double cotton covering,

Digitized by Google

and does not take up nearly so much space. The core plate are insulated from each other by varnish, but a piece of thin paper is placed about every ½in. to supplement it. The plates used vary from about 25 to 30 mils in thickness, and their permeability is specified to be about:

$\mu = 430$ at a density of 15,000 C.G.S. lines per square cm.
$\mu = 50$ „ „ 20,000 „ „ „

these being about the average top densities in the core and teeth.

Cross-connecting rings are nearly always used on machines with over four poles to prevent "bucking." There may be any number of them, but usually three or four are fitted. They are used to connect up all the points in the armature winding, which should be of the same potential, so that if one point is out of balance and tends to have a slightly higher voltage than its correct value, current immediately flows through the low-resistance cross-connecting ring from the other similar potential points on the armature, returning through the armature winding. This extra current causes a greater copper drop in the section which is out of balance, and so reduces its voltage until it is practically the same as the others. The number of points of equal potential in an armature winding is obviously equal to half the number of poles of the machine, hence each cross-connecting ring is connected to this number of points. These rings, of course, tend to even up any slight difference of potential between the brushes of the same sign, thus improving commutation, since the current set up by this small potential difference, which would have flown through the brushes, now flows

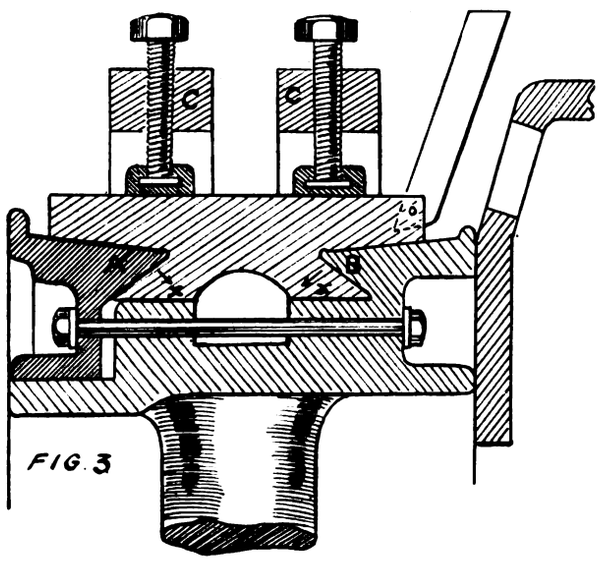

FIG. 3

through the cross-connecting ring, and so prevents the brushes from being overloaded. This current may be very considerable, as the resistance of the circuit is so low.

The commutator is nearly always mounted on a separate casting, which is keyed on to the spindle and butts up against the armature end casting, as in Fig. 3. The bars are of the dovetail or undercut type. The Americans do not like to have an "arch-bound" commutator, which is the usual English practice. By this is meant one which is kept rigid by the pressure between the sides of the bars alone, being supported solely by the two wedge-like projections, A and B, on the commutator body. Hence most of the best firms have the bottom of the commutator bars bearing down on to the commutator body, as at x in figure, and the pressure is put on only by the bottom faces of the two wedges, A and B. Of course, all parts of the commutator body which are touched or near the commutator bars are well insulated with asbestos and mica. The commutator parts are stamped out of copper strip, which is usually bought rolled to the correct level. About ⅛in. is left all round the bar for machinery. The bars are then built up on a dummy commutator body, which is slightly smaller in diameter than the actual one. The bars are insulated from each other with the best soft mica. While the commutator is being built it is held together from the outside by one or more clamping rings, C C_1, as in figure. When all the bars are in place the dummy commutator body is removed, and the commutator squeezed inwards as far as possible by means of the clamping rings. The commutator bars are then entirely held together by the clamping rings. It is then fixed up on the face plate of a lathe, and the inside and ends truly machined to gauge. The angle δ is usually about 10deg. or less, and the angle β is about 20deg. to 25deg. (see Fig 4). The outside is now the only part which is not machined, as the clamping ring is in the way. At this stage, then, the commutator bars are mounted in their position on the commutator body, and the wedge-plates, A, bolted up in place. The commutator is then as shown in Fig. 3. Lastly, the clamping rings are removed, and the whole armature is put in a lathe, and the outside surface of the commutator bars turned up perfectly true with the spindle. Carbon brushes are invariably used, and the current density is about 40 amperes per square inch of contact surface. The brush-holders are usually of the "parallel motion" type. The current density in the armature conductors is usually from 2,500 to 3,000 amperes per square inch, and in the field it varies from 800 to 900.

The speeds of American machines, as noted above, are, however, much less than those of English makers. The table given below shows the speeds and outputs of the General Electric Company's machines taken from their catalogue, compared with a mean English maker's speeds:

Output in kilowatts.	G.E. speed. R.P.M.	English maker's speed.	Approx. eff. Per cent.
25	305	800	85
35	300	650	87
50	280	550	89
75	270	500	90
100	270	450	91
160	230	400	92
200	200	350	92
300	150	350	93
400	150	300	93
550	100	300	93
800	100	250	94

As regards the size of machine required for a given output, each maker has his own rules on this, which have

FIG. 4.

been derived in most cases from tests on his own machines. Mr. Kapp has proved that the output of a dynamo in kilowatts is given by the formulæ:

$$KW. = D^2 L \times \text{revolutions} \times \text{constant};$$

or, in other words, the kilowatts per revolution $= D^2 L \times$ constant,

where D = diameter of machine in inches;
L = length of armature core in inches.

The value of the constant varies very much, indeed, according to the make and size of machine, and the conditions imposed. As a very rough guide we may take it as

8 to 14×10^{-6} for open machines up to 26in. diam. of arm.
20 to 25×10^{-6} „ „ above „ „

TUBE BILLS IN PARLIAMENT.

LORD WINDSOR'S COMMITTEE.

THURSDAY, MAY 15

The House of Lords Committee presided over by Lord Windsor continued the consideration of various "tube" railway schemes proposed for London, proceeding first with the opposition to the Central London Railway extensions.

Mr. Ellis, general manager of the Metropolitan Railway, recalled, said the Metropolitan Company was now about to spend a large sum on electrifying the line, and he thought they were entitled to consideration before further new railways were authorized. He was of opinion that the scheme proposed by the Central London Railway could not possibly prove remunerative. It was expected that the Metropolitan Railway would be run by electricity in 18 months.

Mr. Thomas Parker, M.I.C.E., electrical engineer of the Metropolitan Railway, stated that he was carrying out as rapidly as he could the electric equipment of the Inner Circle. When this was completed the carrying capacity of the Metropolitan and the District

Digitized by Google

would be increased by 40 per cent., and, of course, the ventilation would be immensely improved. He considered the public would prefer to travel in this way than in the ordinary "tubes," on account of the distance to which they had to descend underground, and the long underground passages they had to traverse.

Mr. G. H. Redford, chairman of the Parliamentary Committee of the London County Council, gave evidence as to the views of the Council on the subject. The County Council were of opinion, he said, that some body like the Light Railway Commissioners should be established to which all these schemes should be submitted before they came before Parliament. Meantime they had considered the schemes at present proposed. They were of opinion that power to purchase after a term of years should be given to the local authority. Power was given to purchase tramways overground, but if at any point the tramway got power to burrow underground it got a valuable concession for nothing, and there was no power to purchase. The Council also were of opinion that an enquiry should be held into the question of shallow tramways such as had recently been sanctioned by a committee of the House of Commons. They knew that such an enquiry would involve delay, but the County Council considered the matter of so much importance that they thought the delay would be justified. After considering the present schemes they were in favour of the Central London—first of all, because it would form a good service in itself, and also because it was capable of working into a larger system by exchange stations, because there was not so much danger of inflation of capital with regard to it as in the case of the other schemes, and because a more rapid service of trains could be had on a closed circuit than on the shuttle system.

Replying to Lord Zouche, Mr. Redford said he knew the line from Brompton to Piccadilly had been already sanctioned, and if the Central London scheme was sanctioned there would be two lines under Piccadilly, but he did not think that presented any serious difficulty. The County Council was in favour of the North-East London line.

Mr. Wheeler, K.C., for the Corporation of London, stated that they had come to a similar conclusion as the County Council. They considered the Central London scheme was the most advantageous not only for the City, but for the whole of London. The Corporation was in favour of the North-East London provided it did not come further west than Cannon-street.

Mr. Fitzgerald, K.C., then addressed the committee on behalf of the Central London scheme, and **Mr. Littler, K.C.,** on behalf of the Yerkes group.

FRIDAY, MAY 16.

On the committee resuming, **Mr. Balfour Browne, K.C.,** spoke in the interests of the combined scheme of the Piccadilly and City and the London United Electric Railways Companies for a line from Hammersmith to the City. The first recommendation of the proposal, he said, was that, in conjunction with the North-East London line, it afforded a great through route from the densely-populated parts of the Metropolis to the less densely-populated parts, and, therefore, helped to solve the very important question of the housing of the working classes. Secondly, it provided two important services for London. It conveyed passengers from the north-east to the centre and from the south-west to the centre. The third advantage was that of cheap fares. A fourth point greatly in their favour was that they proposed to make a railway from Clapham Junction to the Marble Arch, giving an important north and south communication, which was offered by none of their rivals. The fifth advantage of their line was that they made a new centre in London, for instead of going to the Bank they had their station at the Monument. As to speed, their service would be quicker than that of the Central London, as they averaged 19 miles an hour, with stops. Both the Central London and the Brompton and Piccadilly-circus companies had become aware of the fact that there must be a railway from Hammersmith along Piccadilly to the City, and they had both attempted to block that route in their own interests and to protect themselves against competition. He ventured to express the opinion that if either of those lines was sanctioned by the committee, it would not be constructed. There was no *bona fides* in either of them. He asked the committee to allow this Bill to proceed for a line which was not only proposed, but which would be constructed.

The room was then cleared, and after an interval of half an hour counsel and parties were readmitted.

The **Chairman** said the committee had decided not to proceed with the Central London Bill as far as related to the proposed railway from Shepherd's Bush *via* Hammersmith to the Bank, but they were prepared to consider the extension of their line beyond the Bank and the small branch lines at the West-end. With regard to the Brompton and Piccadilly Bill, the committee would not proceed with that portion of their proposed line between Piccadilly-circus and Charing Cross, leaving the other portions for future consideration. With regard to the London United Electric Railways, Piccadilly and City, and North-East London, the committee would not proceed with that portion of the United Electric Railway which ran from Addison-road *via* Shepherd's Bush to Hammersmith. The committee would meet on Monday week, and they proposed then to proceed with what further opposition there was to the United Electric combined scheme.

The committee adjourned.

LORD RIBBLESDALE'S COMMITTEE.

The result of the deliberations of this committee, which closed their sittings on Wednesday week, may be summarised as follows: Charing Cross, Euston, and Hampstead (Nos. 1, 2, and 3), passed; Edgware and Hampstead, passed; Islington and Euston, rejected; City and Crystal Palace, rejected; Great Northern and City, passed; Great Northern and Strand, passed; North-West London, passed; Baker-street and Waterloo, passed.

DISCUSSION IN THE LORDS.

An interesting discussion on the subject of what provision should be made to protect property owners from damage due to vibration, took place in the House of Lords on Thursday last week on a motion by the **Earl of Camperdown** that the special clauses to be proposed with reference to the damage done by underground railways be submitted for consideration by the House before being inserted in any Railway Bill. He said that special clauses had been drafted, and were now under consideration by private Bill committees. But he thought that, as these or similar clauses would probably in future be applied to all Bills relating to underground railways, this procedure involved a question of general policy, and, practically, an alteration in the general law. The clauses, therefore, in the first place, should be laid on the table of the House so that their lordships and the public might become acquainted with them, and that any questions might be raised in regard to them. They should come before the House in the same way as general Bills, for they affected the original jurisdiction of their lordships with which they should be slow to part to committees.

The **Earl of Morley** said that tube railways were novel, and there was practically no experience to guide them in deciding what damage might be done to adjoining property by their construction. He entirely agreed with the noble earl that something ought to be done. He also sympathised with his wish that the House of Lords should be thoroughly informed of all the clauses introduced into private Bills to further the object which he, and the House also, he believed, had in view. But the committees, whose members were considering with great care the clauses embodying suggestions as to what should be done to give further protection to owners of property than they had under the present law, had the great advantage of having the cases for the promoters of the railways and for the owners of property before them. The suggestions were being thoroughly discussed by counsel. It would be better to leave the elaboration of the clauses to the committee in the first instance. It would be perfectly open to the House afterwards to consider these clauses and make any alteration they thought fit. He would be happy to inform the noble earl when the Bills were coming on for third reading so that he could call attention to the clauses and take the opinion of the House upon them, which would be a guide to future committees and to himself. He suggested this as the more convenient course.

Eventually the motion was withdrawn on the undertaking of the Earl of Morley that the House should have copies of the new clauses before the third reading of the Bills.

FORTHCOMING EVENTS.

FRIDAY, MAY 23.

Physical Society. — At 5 p.m., ordinary meeting. Papers: "On the Ebullition of Rotating Water: a Lecture Experiment," by Mr. T. C. Porter; "The Conservation of Entropy," by Mr. J. A. Erskine; "Rational Units of Electromagnetism," by Mr. G. Giorgi.

THURSDAY, MAY 29.

Institution of Electrical Engineers (Dublin Section).—At 8 p.m., annual general meeting. A paper will also be read entitled "The Lighting and Driving of Textile Mills by Electricity," by Mr. M. Osborne.

Society of Arts (Colonial Section).—At 4.30 p.m., ordinary meeting. Paper: "Western Australia: Its Progress and Resources," by the Hon. H. W. Venn.

FRIDAY, MAY 30.

Royal Institution.—At 9 p.m., Mr. G. Marconi on "The Progress of Electric Space Telegraphy."

The Incorporated Municipal Electrical Association will hold its seventh annual convention in London from July 2 to 5.

APPOINTMENTS VACANT.

Switchboard Attendant, Eccles Corporation electricity works, £62 per annum, May 24.

Borough Electrical Engineer and Tramways Manager, Newport (Mon.) Corporation, May 31. Full particulars may be obtained from the town clerk.

Draughtsman, Leicester Corporation borough engineer's office, £135 per annum, May 27.

Demand-Note Clerk and Collector, Stepney Borough Council electricity department, £100 per annum, rising by annual increments of £10 to £150, May 30. See advertisement.

Assistant Engineer, Wimbledon Urban District Council Electricity Department, £78 per annum, May 28. See advertisement.

Mechanical Draughtsmen, with electrical experience. See advertisement.

Shift Engineers, Coventry Electricity Works and Cork Electric Tramway and Lighting Company, Cork, 45s., May 29. See advertisements.

Junior Switchboard Attendant, Hoylake and West Kirby Urban District Council, £52 per annum, May 28. See advertisement.

PRINCIPLE OR NO PRINCIPLE.

The moderate man has to take the kicks of both extremes, and never looms largely in the eyes of the world because he does not tub-thump loud enough. Likewise, he generally pays the piper, but does not call the tune—that is because the right way, which lies between the two extremes, is scarcely or never followed, the way tending toward the stronger or more blatant extreme. No doubt the first tramway was somewhat of the nature of an accident, likewise of an expedient. It got put down in a public street because that street was almost impassable to ordinary vehicles, and no one troubled about principle or what the future would bring forth. Upon what principle did the original tramway companies obtain their powers? We presume, like most new introductions, parliamentary sanction was obtained, but as there would be no opposition, and Parliament acts through expediency and not by principle, always taking the line of least resistance, sanction was easy. Once sanction obtained, precedent would hold good, and promoters only had to show a bolder front and a longer purse than opposers to make their case good and obtain what they asked for. The poor, long-suffering public was ultimately recognised, and tramway work harried and rendered almost impossible by limitation of time of ownership, with subsequent loss of control and property without due reward. He would be a bold man who to-day would argue that tramway traction did not interfere more or less with the general use of the street; and the question is being asked with greater emphasis every day, in what way are the rights of the general public to the street surface being considered? The frontagers have a say for or against a given tramway, but these are not the only people who use the street surface and whose business meets with interference. Colonel Crompton and others have been suggesting the formation of new main roads, contending that the nation has not in this respect kept up with the requirements of the times. They hold that automobilism is the coming tractive power, and that its free development is restrained because of the restrictions laid upon automobilists. Quite so, but if there were fewer impediments in existing streets, there would be greater room for the newer traction. However, we contend that the street surface is for the benefit of the whole community, and that the danger is arising when freedom of use of the streets will be impossible. If a tramway is considered to be an improvement upon the existing state of things and does not seriously interfere with the other traffic, then no serious harm can arise, but undoubtedly the Legislature is far too lax in allowing schemes which do seriously interfere with other traffic. In such cases, if a tramway is constructed, it should be constructed upon its own ground, and not upon street surfaces, which in the nature of the case are public property. Take as a last example of legislative action—the so far probable permission to construct a tramway along the Thames Embankment—the only road from East to West not at present seriously overcrowded. The construction of this tramway is promoted, we firmly believe, not because its promoters are convinced of its utility, but as a means to employ a stronger lever in the future for southern lines to cross the bridges. Parliament can make and unmake laws, but in its unrestricted permission to build tramways by those who possess the longest purse and most impudence it is going periously near to becoming the weakest link in the constitution. We conclude by again asking, what principle is followed in allowing the hundred and one interferences with streets, the aim of each one of which is to benefit a limited number, and not the whole of the community? If there is no underlying principle, and each

Digitized by Google

case is considered upon its merits, the sooner some principles are evolved the better, for "merit" in some cases simply means length of purse and persistency. Colonel Crompton's statement that tramway traction is nearly, if not quite, the worst method of moving a mass of humanity from a given point and distributing the items to other points, put forward in his inaugural address to the Mechanical Section of the British Association, has never been seriously disputed, much less disproved, and till it has been proved incorrect more weight should be given to the opponents of schemes when the schemes involve the partial blocking of old and narrow streets.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE INSTITUTION OF ELECTRICAL ENGINEERS AND THE PROPOSED "MODEL GENERAL CONDITIONS" FOR ELECTRICITY WORKS.

SIR,—I was much surprised to read in your issue of May 16 that during the adjourned discussion on the above subject, "Mr. Shoolbred having spoken in favour of the document," etc. I beg to say that I did nothing of the kind. Any remarks that I made were quite to the contrary, more especially as to the tendency which pervaded the whole of the document to make the contractor, and not the consulting engineer, the exponent of the views of the intending purchaser. This is evidenced especially by the clauses as to the drawings, the whole of which, including even the preliminary drawings, are to be supplied by the contractor.

I have always been given to understand, during the experience of a fair number of years, that it is by means of the architect or the consulting engineer that the intending purchaser seeks to explain to intending contractors the nature and extent of the works which he is desirous of having constructed.

If, instead of the purchaser's views being explained by his own adviser to the contractor, it is the contractor who is good enough to explain what he is prepared to supply in order to comply with the purchaser's requirements (as is proposed in the model general conditions), it is quite conceivable that the intending purchaser may somewhat differ as to what are his own requirements, and he might prefer that his own adviser should be the exponent on his behalf of his own views and requirements.—Yours, etc.,

JAMES N. SHOOLBRED.

32, Victoria-street, S.W., May 21, 1902.

REVIEWS.

The 1902 Edition of the General Electric Company's Complete Catalogue.

For the third time the General Electric Company have gathered together under one binding the whole of the range of catalogues and price-lists which they issue for their various departments. The binding of this third volume is coloured red and green to distinguish it from the others, and the book so made can be used for a great variety of purposes. As a whole it is a useful adjunct to the library of an electrical engineer, and in an office its weight alone renders it of service. Thus with practice it can be used with effect to speed the departure of an unwelcome visitor. The internal value, however, far surpasses its service as a projectile. Thus in it one can select any article used by electrical engineers, from the 1,500-kw. central-station dynamo down to the curling tongs for ladies, to which new stations are invariably counselled to look for their load. Another range of subjects varies from the telephone equipment for a large town to the electric alarm warranted to wake the dead at sunrise, or the apparatus for enabling a man to estimate the anatomical value of his own skeleton. From this catalogue one can purchase electric fittings of almost innumerable shapes and types of finish, and the price one can pay is also varied, from the cheap plain pendant up to works of art listed in guineas. In fact, the present volume is more complete than any other catalogue we know of, and it speaks well for its editors that its index and arrangement allow of any desired article being quickly turned up. The first few pages give illustrations of the various works of the company over which their 5,000 employés are distributed. These include the new carbon works at Witton, which form a comparatively small part of the huge electric manufacturing shops now nearly completed. At the carbon works arc lamp carbons are now being turned out in large quantities, these reviving what has been practically a lost industry in this country. In connection with the Witton works, near Birmingham, the company are erecting a large number of cottages for their employés on adjacent land. This will prevent the scandals over the housing question which have attended the moving of other large firms to new works.

We next find a host of useful information printed on a pink supplement—for those who wish to buy, sell, or manufacture—written specially in popular style, so that the retailer, who has not the implements of a drawing office or library always at hand, may be able to benefit equally with the trained engineer. Here we find, besides the indices mentioned above, tables of weights and measures with metrical equivalents, foreign money tables, data for house wiring, and comparison with gas for private plants, hints to purchasers, and a glossary of electrical terms. For those Colonial customers who have not always time to write home for quotations, a series of estimates for complete plants are included, and, finally, there is the General Electric Company's special telegraphic code, by means of which any of the 100,000 listed articles in the catalogues can be cabled for in conjunction with the ordinary commercial codes; and many electrical and mechanical expressions are coded as well, so that orders can be sent for all requirements.

We now come to the catalogue proper, which comprises the following sections: (S) switchboard and electric light supplies (80 pp.); (W) wires and cables (56 pp.); (M) instruments, meters, etc. (40 pp.); (E) arc lamps and engineering specialities (112 pp.); (T) traction supplies (16 pp.); (P) electrical plant (56 pp.); (H) electrical heating and cooking (24 pp.); (L) electric bells, etc. (95 pp.); (K) telephones, etc. (96 pp.); (O) electro-medical apparatus (32 pp.); (F and G) fixtures and glassware (272 pp.). At the end of the catalogue there is an art paper supplement with some excellently reproduced photos, showing the great variety of and enormous field covered by the installation work of the General Electric Company—from dynamos and switchboards to lighting and street telephones.

All these sections aggregate close on 1,000 pages, and (with few exceptions as in lamps, where the varieties are too great) every article has a catalogue number, and every class of article is accompanied by a short and concise description and specification, which can be embodied by contractors in their own estimates. These specifications and the blocks are so clear that no doubt can arise in the minds of buyers as to the quality or appearance of the article desired. All the articles illustrated are manufactured by the General Electric Company, and there is, therefore, no wonder that, in spite of their London, Birmingham, and Manchester works, they have had to go into the country to build additional works. As we have from time to time reviewed the various sectional catalogues a detailed description here is not needed, but a few remarks on the section which deals almost exclusively with dynamos and motors will not be out of place. Here we find the well-standardised "Byng-Hawkins" multipolar dynamos and motors, open and enclosed types, single and polyphase generators and motors, and various appliances connected with these. It is expected that the opening of the Witton works will make this section in future one of the most important catalogues issued by the firm. A yellow supplement completes this part, in which steam, gas, and oil engines, boilers, and other prime motors, not made by the General Electric Company, are listed for the special benefit of buyers abroad.

Digitized by Google

In conclusion, we can only repeat our remarks made in previous editions, that the General Electric Company's catalogue is an absolute necessity to electrical engineers.

"THE ENCYCLOPÆDIA BRITANNICA."

We have received a copy of the first of the new volumes of "The Encyclopædia Britannica," now being published by the *Times*, of Printing House-square, London, and by Messrs. Adam and Chas. Black, of Edinburgh and London. The new volumes now being issued will form in combination with the existing volumes of the ninth edition a complete encyclopædia. The first volume of the new series deals with additions required under letter "A," and contains two important articles of interest to electrical engineers The first of these is contributed by Mr. W. Hibbert, F.I.C., F.C.S., on "Accumulators." Mr. Hibbert's work in this direction is well known to electrical engineers, and the article, taking up some 10 pages of the encyclopædia, is worthy of careful perusal even by those who have a good general knowledge of the subject. He begins by explaining that the names given to Planté's first cell have been frequently misunderstood. The terms "secondary battery," "storage battery," and "accumulator" have been taken to indicate that there was an accumulation or storage of electricity or of electric current, but the error is not Planté's, as is clear from his declaration that his couple is able to give discharges of long duration, or to retain its charge for a long time, *et d'emmagasiner ainsi le travail chimique de la pile Voltaique*. The value of the cell arises from a happy combination of properties. The three active materials are peroxide of lead, spongy metallic lead, and dilute sulphuric acid. Of these the peroxide is an excellent depolariser; the lead is a sufficiently good electro-positive metal; and the dilute sulphuric acid has a very high conductivity for an electrolyte. Moreover, the two solid substances are not only themselves insoluble in the dilute acid, but the sulphate of lead formed from them in the course of discharge is also insoluble. Consequently it remains fixed in the place where it is formed; and on the passage of the charging current the original PbO_2 and Pb are reproduced in the places they originally occupied. Thus there is no material change in the distribution of masses of active material. Lastly, the active materials are in a porous, spongy condition, so that the acid is within reach of all parts of them. The resistance of the cell is low, while the energy of the chemical action to which it gives rise imparts a high E.M.F.

After reviewing the early work done by the above-mentioned experimenter, illustrations are given of the best forms of accumulators as manufactured at the present day, in order to show the forms of construction which have given the greatest success in regular work. The author, before going fully into the theory of accumulators, explains the need of the three active substances used in them, which consist of spongy lead on the negative plate, spongy peroxide of lead on the positive plate, and dilute sulphuric acid between them. The fourth substance—sulphate of lead—is also formed during the discharge, and also to a small extent during repose. The author gives the following figures for the density and specific resistance of the above substances. Spongy lead has a density of 11·3 and a resistance of ·00000195 ohm between the opposite faces of a cubic centimetre. The spongy peroxide of lead has a density of 9·28, and a specific resistance varying from 5·59 to 6·78 ohms. Sulphate of lead is a white powder with a density of 6·3. Its electric conductivity is so low that it may be classed as a non-conductor. The densities of these three solids being known, it is easy to follow the changes in volume which accompanying the formation of sulphate of lead on either plate. One hundred volumes of lead (on the negative plate) form 290 volumes of sulphate, and will, therefore, require three times as much space as before the action, while 100 volumes of peroxide (on the positive plate) form 186 volumes of sulphate, and will, therefore, fill nearly twice as much space as before. These expansion figures are not only important in themselves, but also throw light on the well-known tendency of the negative plate to run down before the positive. In a given discharge the quantities of sulphate of lead formed on the two lead plates are the same, but the expansion in the lead plugs (and consequent reduction of porosity) is 60 per cent. greater than in the positive plugs.

The author goes on to deal with the local actions which occur in accumulators and with the theory of accumulators generally. In so doing he gives a large number of curves obtained from experimental working under various conditions, which are of great interest. No less than 34 illustrations are used in the article, which concludes with a description of the accumulator cars used at Birmingham, and the advantages which may be derived from the employment of accumulators in a traction generating station.

The other article referred to above as appearing in the first of the new volumes deals with atmospheric electricity. This has been contributed by Dr. C. Chree, D.Sc., F.R.S., of the National Physical Laboratory. He commences by showing that investigations into the early history of atmospheric electricity would be the province rather of the antiquary than of the scientific man. In pre-scientific days lightning was usually regarded as the special vehicle of divine vengeance. Lucretius was perhaps the first who attempted to apply to its elucidation the scientific method. He pointed out that even the temples of Jupiter had not escaped the thunderbolt, which seemed to imply an incredible degree of inefficiency in the department over which that divinity was supposed to preside. Like most modern scientific men who have considered the subject, Lucretius had a theory of his own, and he might almost be looked upon as the parent of the "electric fluid" phraseology still so prominent in popular writings. Even in 1749, when Franklin proposed the famous kite experiment to test the identity of natural and artificial electricity, the electric fluid theory was probably held by most scientific men in a fairly literal sense. The electric fluid was supposed to reside in the clouds, whence it was attracted by any sharp point held upwards. Shortly after 1750, the observations by Lemonnier and others of electric phenomena in the atmosphere in the absence of cloud, led to some modification of ideas. It was only, however, with the introduction of improved methods and apparatus after the middle of the nineteenth century, mainly by Lord Kelvin, that there was any approach to exact measurements of atmospheric electricity. To understand the different methods employed or recommended, a brief survey of the phenomena is necessary.

At most places, in dry weather the electric potential near the ground is normally positive relative to the earth, and increases with the height. The existence of earth currents shows that the earth, strictly speaking, may not be all at one potential, but the potential differences between points on the earth's surface, say 1 km. apart, are insignificant compared to the normal potential difference between the earth and a point 1m. above it, and when considering this latter difference we may regard the earth as at a uniform zero potential. What is aimed at in ordinary observations of atmospheric electricity is the measurement of the potential difference between the earth and a point at a given height above it, or else the difference in potential between two points in the same vertical at a given distance apart.

The addition of sharp points was a step in advance. But the method can hardly be said to have been a quantitative one until the sharp points were replaced by either a flame (fuse, gas, lamp) or a liquid jet breaking into drops. In either case the theory is the same. The matter leaving the conductor, whether it be the products of combustion of a fuse, or the drops of a liquid, supplies the means of maintaining equality of potential between the conductor and the air at the spot where the matter quits electrical connection with the conductor.

He then discusses the older methods of dealing with the electrification of air, and describes in detail the advances made in such work under the guidance of Lord Kelvin, who substituted either the flame or liquid dropping apparatus for the water-dropper electrometer for the older methods. Interesting tables of the mean diurnal inequalities in atmospheric electricity as measured in observatories

Digitized by Google

in various parts of the world in different years are given and commented on by the author, who proceeds to draw conclusions from the same. For instance, he shows that a certain high thunderstorm frequency and low potential gradient vary in parallel lines. Thus, thunderstorm frequency and intensity are greatest about midsummer, when potential gradient is least, and there is at most stations a minimum of potential gradient in the afternoon at about the same hour as the thunderstorm maximum. The connection is, however, far from close. Thus we have the thunderstorm minimum occurring alongside of the early morning potential gradient minimum; and the diurnal and annual variations in thunderstorms appear much more accentuated than the corresponding variations in potential gradient.

The last part of this article deals with the phenomenon of aurora, of which much work has yet to be done. Dr. Chree comments on the fact that at the Danish polar station, Godthaab, Paulsen saw on several occasions auroral sheets, which seemed to be suspended vertically like curtains, and to sweep past with great velocity, travelling from magnetic south. At Paulsen's suggestion, Lieutenant Vedel, of the Ryder Arctic expedition, 1891-1892, kept a look-out for this phenomenon, and was able on a variety of occasions to observe the declination magnet during its occurrence. According to these observations—made on an island in Scoresby Sound, 70° 27′ N. lat.—the needle moved to the west as the auroral curtain approached from the south, oscillated as the curtain passed overhead, and then moved to the east as the curtain receded towards the north. Paulsen believes the phenomenon to imply the existence of an electric current directed downwards in the space occupied, or seemingly occupied, by the auroral curtain.

Numerous attempts have been made to determine the height of auroral displays. Simultaneous theodolite observations have frequently been made from two stations at a considerable distance apart. The calculated heights in mean latitudes have often exceeded 100 km. At Godthaab the calculations of the Danish observers often put auroral arcs at heights under 10 km., and occasionally under 2 km. From the observations at Sodawkyla, Lemstrong thought it doubtful whether the objects seen from the two ends of the base were really the same. The question has been treated with great fulness of detail by Cleveland Abbe ("Terrestrial Magnetism," vol. iii., 1898, pp. 5, 53, and 149). He seems disposed to doubt whether what the observer sees as aurora has an independent objective existence.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

483. Six 400-kw. machines connected across the outers in a three-wire station are on load; five of them are excited from the station 'bus bars, the sixth being a self-exciting machine. The armature bands of this self-exciting machine give way, and, jamming between the pole-pieces, earth the armature and blow the fuses on the main switchboard without affecting the + or − volts in the slightest. On examining the recording voltmeter cards afterwards a very slight drop is noticed a while before the main fuses went; at the point where the fuses did blow a slight rise is noticed. How can this be satisfactorily explained?—R. M.

484. In an Allis three-line engine of 4,000 h.p., driving a traction generator, the diameter of the shaft is increased in each successive line approaching the armature. Is this practice to be recommended as sound engineering? State reasons for or against.—C. I. S.

ANSWERS.

Question No. 477.—Explain the use and object of the fourth wire when used in connection with the distribution of three-phase current.

Best Answer to No. 477 (*awarded* 10*s.*).—One of the chief reasons for using a "fourth wire" in connection with the distribution of three-phase current is economy. To demonstrate this saving in copper due to the presence of the neutral or fourth wire in polyphase working, is quite easy. When a simple three-core cable is employed, the consumer's service wires are for lighting purposes attached to adjacent conductors, but when a fourth or balancing wire is added, the consumer's service wires are connected between any one of the three principal conductors and the fourth wire. From this it follows that if in each case the difference of potential in the consumer's premises is the same, the pressure between the three principal conductors can, when a neutral conductor is added, be increased over the pressure between them when there is no such conductor in the ratio of $\sqrt{3}$ to 1—in other words, while retaining the same pressure at the consumer's terminals, we can, when there is a fourth wire, raise the pressure on the three wires in this ratio, and seeing that the weight of copper is inversely as the square of the pressure for the same percentage loss, so far as the three principal conductors are concerned, the weight of copper is at once reduced to one-third. Let the neutral conductor which has to be added bear the same proportion to the combined area of the three principal conductors as in the three-wire continuous system, and we have the total weight of copper with neutral as only five-twelfths of the weight of the three-core cable—that is, considerably less than half. The advantage of using a fourth conductor for three-phase distribution will then be apparent. There are several methods of arranging the low-tension network with a neutral conductor. Fig. 1 shows one method which is used

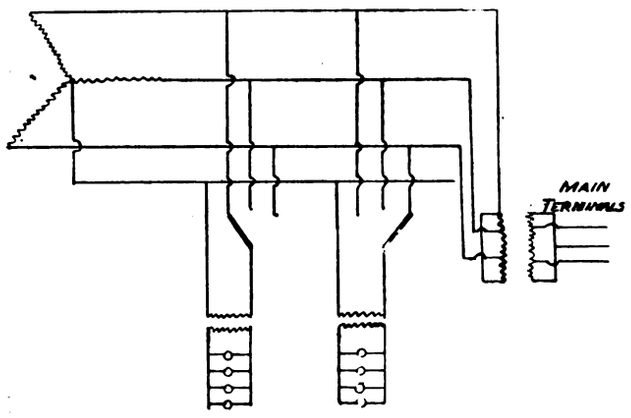

Fig. 1.

chiefly in America. From the station three-phase feeders are run each capable of supplying 500 kw. or more, these long feeders delivering power to areas, say, of a couple of miles in radius such wise that all consumers may be connected by short single-phase branches tapped off from one outside wire and the neutral. The necessary transformation is done by means of an ordinary transformer wound for whatever the system may be and the declared voltage on the secondary. This transformer either supplies an individual customer or a small local three-wire secondary network, the various branches being arranged to give a balance as near as possible. When motors are required to be operated they may be run from the three-phase mains, "delta" connected transformers preferably being used, or, perhaps, better still, a three-phase transformer, as this would be a very good balancer. It would be advisable (in fact, the Board of Trade require it) to earth the neutral wire in order that no potential difference other than that for which it is designed should be thrown on the transformer. This system is so connected together that motors can be operated with practically no effect on the lighting. No instance of this as yet exists in this country so far as I am aware; but the important scheme which is being arranged for Dublin on a different plan to the above may

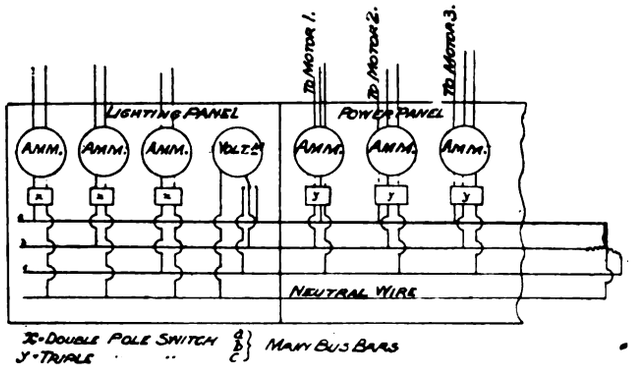
Digitized by Google

no doubt be followed by others, especially as the manufacture of induction motors will shortly be freed from the restrictions imposed by the Tesla patents.—A. G. S.

Answer to No. 477 (*awarded* 5*s.*).—If a three-phase installation is put down for motor power work only, there will be no necessity for having a fourth or neutral wire; but if it be intended to light the premises off the three-phase generating plant, it may be advisable to adopt a fourth-wire system.

Let us assume the current is generated at an E.M.F. of 400 volts; if the machine is star-connected the E.M.F. between any of the main leads will be 400 volts, but between any main lead and the neutral wire the E.M.F. will be $400 \div \sqrt{3} = 230$ volts. There are three methods, then, by which a lighting distribution can be carried out in connection with a three-phase current motor-power installation: (1) by connecting up the lamps in series across a pair of mains; (2) by reducing the E.M.F. by means of static transformers connected across pairs of mains; (3) by adopting the fourth-wire system.

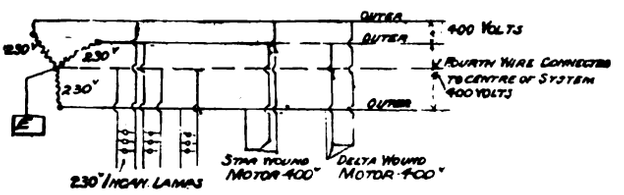
It must be borne in mind that the load on each pair of mains should be as nearly equal as possible, whatever be the system adopted. Thus, call the three main leads *a*, *b*, and *c*. If the lamps are connected in series, the same number should be connected across *a* and *b* as across *a* and *c* and *b* and *c*. Also, with static transformers the current taken from *a b* must equal that from *b c* and *a c* respectively.



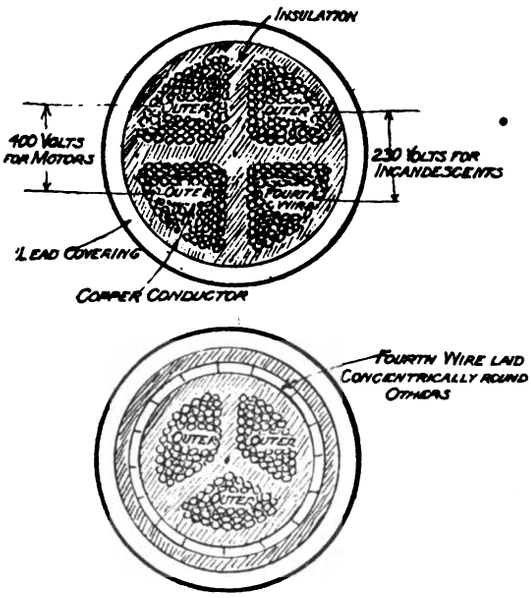
This is not an absolute necessity, but in order to obtain a good balance the loads should be kept as nearly equal as possible. When the fourth wire is used, the load between it and *a*, *b*, and *c* should also in each case be kept equal.

Each of the above methods of lighting distribution has been adopted in different contracts, and good results have been obtained from each. A typical case of the fourth-wire system is shown in the installation at the Bristol Carriage and Wagon Works. The figure is a diagrammatic sketch of a distribution board for a four-wire system. It will be noted that each lighting circuit is protected by a double-pole switch, the supply being taken from one of the main 'bus bars, and the 'bus bar connected to the neutral line, while each motor is protected by means of a triple-pole switch, the supply being taken from the three main 'bus bars. If this distribution board is fixed some distance away from the generating plant, the size of the neutral wire will depend upon the degree of balance between the three lighting circuits, as the only current which flows along this between the generating plant and the distribution board is that due to imperfect balance. The wire between these points may be considered as equivalent to the middle wire in the case of a three-wire direct-current distribution.—M.

Answer to No. 477 (*awarded* 5*s.*).—The fourth wire on a three-phase system is generally used when the mains distribute current to consumers for both lighting and power. It is used where the connections are on the star system of three-phase distribution, and acts in a similar way to the middle wire of a three-wire direct-current system—*i.e.*, as a balancing wire to provide for the return of any out-of-balance current which may be produced by the lighting load being unequally divided on the different sides of the system. It also enables us to make use of *two* voltages, as explained below, and a considerable economy is effected in the amount of drop for a given lighting load, or, in other words, less copper can be used for a given drop. The accompanying diagram shows connections and explains itself. The three outer conductors are connected up to the outer ends of the three legs of the star-wound



machine (or transformer) in the ordinary way for three-phase working, and the fourth wire is connected to the centre of the windings and also earthed at this point. The fourth conductor may be small in comparison with the other three, but is generally made the same sectional area, as it is just as well to have some spare copper and it makes a better cable. These cables are generally built up as per accompanying sketches.



Referring to the diagram of connections, suppose there are 400 volts between any two outers, then there will be $\frac{1}{\sqrt{3}} \times 400 = 230$ volts (approximate) between any outer and the middle wire. Motors either star or delta wound could be connected between the three outers, thus keeping the system always balanced as far as the power load is concerned. The incandescent lamps for lighting can be connected up at 230 volts between either of the three outers and the fourth wire, and these can be well balanced between the three sides of the system. The balancing is obviously about 30 per cent. easier than in the case of the ordinary three-wire direct-current system. Without the fourth wire the voltage between any two mains would be too high for incandescent lighting, or if the voltage *was* made suitable for incandescents, then the voltage between outers would be somewhat too low for efficiency in motor driving, to say nothing of the ease of balancing by means of the fourth wire and the economy of drop.—J. A. Morton.

Answer to No. 477 (*awarded* 5*s.*).—Three currents of equal average value, alternating according to three sine functions 120deg. different in phase, will have their algebraic sum at any moment equal to nothing; hence if in a three-phase system (1) equal E.M.F.'s are generated in three phases, (2) these are loaded equally, the phases can all be connected to a common point, the ends of the generator winding being also connected to another common point, and since these points are at the same potential, there will be no need for a return wire between them.

The use and object of the fourth wire, when used in connection with the distribution of three-phase currents, is to regulate the voltages on the three phases when this is rendered necessary (generally by the non-fulfilment of condition 2 above). Where a fourth wire is used, the star grouping must be adopted, and the wire is brought back to the common junction of the three circuits

Digitized by Google

of the generator, and serves to equalise the pressures whenever the loads in the three branches are unequal. This inequality will evidently not exist where the system only supplies three-phase apparatus, such as motors, which will take an equal amount of current from each branch. The difficulty arises chiefly in cases where lamps have to be supplied, but experience has shown that the fourth wire is even then not always indispensable. A three-phase equaliser can be added at some convenient point in the distribution. This consists of a three-phase choking coil, the three windings of which are united star fashion, the fourth wire of the circuits being brought to their common junction. When a three-phase transformer has its three cores connected together, so that the magnetic circuits are combined, it will exert an equalising effect, and induction motors are also found to have a similar influence.—A. L. R.

Question No. 478.—With a condenser to be capable of dealing with 12,000lb. of steam per hour, with cooling water at 60deg. F. to 75deg. F., and to sustain a vacuum of 26in., what is the best method of arriving at the diameter, stroke, and bucket speed of both single-acting and double-acting vertical air-pumps, also speed of water through the foot and head valves for single-acting bucket pump (Fig. 1)? Also speed of water through suction and delivery valves for double-acting piston pump (Fig. 2)? Also capacity of jet condenser and cooling surface required for surface condenser?

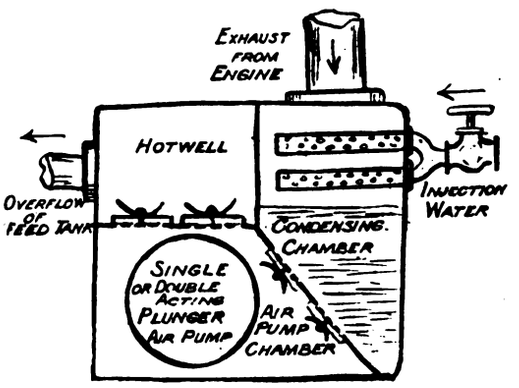


FIG. 1.

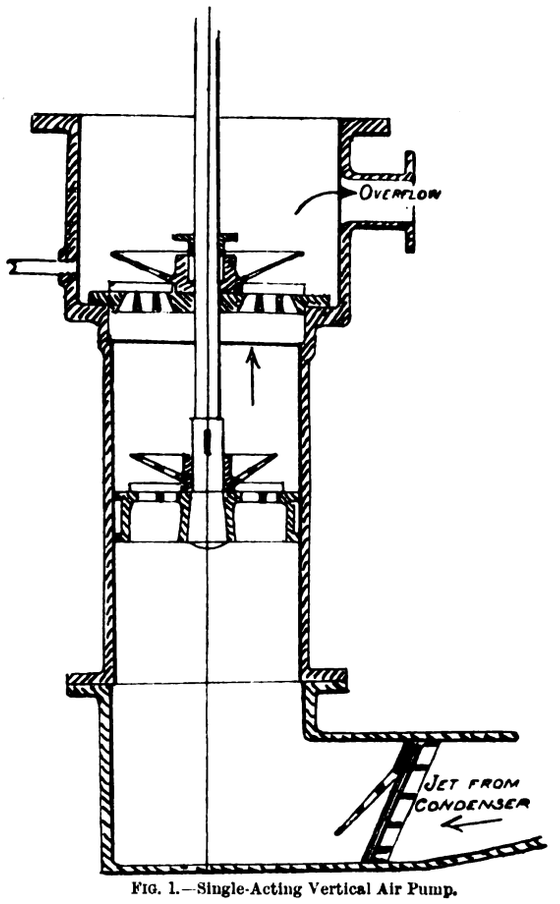

FIG. 1.—Single-Acting Vertical Air Pump.

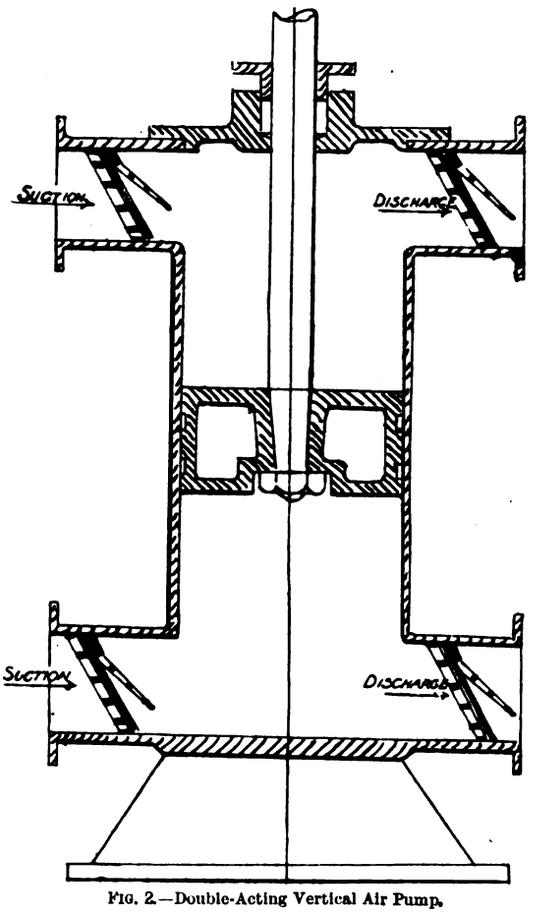

FIG. 2.—Double-Acting Vertical Air Pump.

Best Answer to No. 478 (*awarded* 10*s.*).—This question may be divided into two parts: (1) required the capacity of jet condenser, and particulars of single-acting and double-acting air-pump for same; (2) required the same for a surface condenser. Let us take the points in this order.

1. *Jet Condenser.*—This usually consists of a square box-like casting divided into three parts, as in Fig. 1: a condensing chamber, air-pump chamber, and hot-well. Owing to the fact that there is such a large clearance in the air-pump chamber—*i.e.*, space *not* swept through by the piston—due to the special design adopted, the vacuum obtained is not so good as that of a surface condenser. It is very difficult to get more than 24in. of vacuum, and certainly 26in. could not be obtained. Assuming this to be good enough, however, we can get out a rough design for one as follows: The cubical capacity of the condensing chamber should be from one-quarter to three-quarters that of the cylinder discharging into it according to the speed. For medium-speed engines one-half is about correct. The exact proportion varies very much according to the maker and the conditions of service. A rule which holds well in practice is to make the capacity of the condensing chamber about seven to eight cubic feet for each 1,000lb. of steam condensed per hour. According to this rule, it ought to be in this case = 8 × 12 = 96 cubic feet.

The Size of the Air-Pump.—This pump has to withdraw both the condensed steam and the injection water from the condenser. The condensing water required can be found as follows: The latent heat in 1lb. of steam at 24in. vacuum (= 3lb. absolute pressure) is about 1,016 B.T.U.'s per pound. The temperature of the hot-well should be about 110deg. F. say, hence the loss of sensible heat by the steam will be (140deg. – 110deg.) = 30 B.T.U.'s per pound, since 140 is the temperature corresponding to 24in. vacuum.

∴ The total heat given up per pound of steam = 1,016 + 30 = 1,046 B.T.U.'s.

The heat gained per pound of condensing water = 110 – 70, say = 40 B.T.U.'s.

∴ Number of pounds of condensing water per pound of steam $= \frac{1,046}{40} = 26.$

The air-pump in a jet condenser is nearly always worked from the engine; let us suppose that it makes 180 revolutions per minute. Now, the limit of speed at which it can

Digitized by Google

be run depends on that at which the water will follow it. This is theoretically 15ft.-16ft. per second; allowing for friction we might get 12. To avoid shocks and whirls, however, it is well to take it much lower, say 8ft. per second. The exhaust steam is 12,000lb. per hour

$$= \frac{12,000}{180 \times 60} = 1{\cdot}11\text{lb. per revolution.}$$

Condensed steam and injection water per revolution
$= 1{\cdot}11 + (26 \times 1{\cdot}11)$
$= 30{\cdot}1\text{lb.}$

Now, the air-pump has not only to exhaust this, but has also to pump out any air which leaks in, in order to maintain the vacuum. Also, there is always a certain back-rush of water just as the valves are closing at the end of the suction stroke. For these reasons we make an allowance of about 50 per cent.—*i.e.*, when working, the air-pump will only be about half full of water.

Suppose, first, the pump is *single-acting*; then each revolution of the engine corresponds to one effective stroke of the pump, during which it has to pass 30lb. of water.

Now, 1lb. of water = 27·6 cubic inches.

$\therefore$ 30lb. of water = 27·6 × 30 = 828 cubic inches.

Doubling this as explained above = 1,656 cubic inches.

Now, each revolution takes $\frac{60}{180} = \frac{1}{3}$ second.

A stroke takes half this = $\frac{1}{6}$ second.

$\therefore$ at 8ft. per second stroke $= \frac{8}{6} = 1{\cdot}335\text{ft.} = 16\text{in., say.}$

$\therefore$ area of pump plunger $= \frac{1,656}{16} = 103{\cdot}5$ square inches,

and diameter of pump = 11½in. (approximate).

If the air-pump is double-acting, we need only make it half the size. We may, therefore, halve the stroke if we wish, so getting a speed of only 4ft. per second, which is really too good; or we may reduce the speed to 6ft. per second, which is a very good figure, indeed, making the stroke 12in. and the diameter 10in. The latter is probably the best thing to do.

2. *Surface Condensers.* — Here the condensing is done by passing the steam through a nest of tubes which have the cold condensing water circulating in them. The tubes are usually of gunmetal §in. or ¾in. outside diameter, and about $\frac{1}{20}$in. thick. The amount of tube-cooling surface required is about 1 1 to 1·4 square feet per indicated horse-power for engines about 500 h.p. A fairly good rule which agrees well with practice is to take one square foot for every 10lb. of steam condensed per hour. Thus in this case cooling surface $= \frac{12,000}{16} = 1,200$ square feet. Assuming tubes to be 6ft. long and §in. in diameter, each tube has

$$\frac{{\cdot}625 \times \pi}{12} \times 6 = {\cdot}98 \text{ square feet.}$$

$\therefore$ number of tubes required $= \frac{1,200}{{\cdot}98} = 1,225.$

Assuming pitch of tubes to be 1in. approximate, external diameter of condenser if round = 3¼ft. to 4ft. roughly.

The Air-Pumps are here separate, and owing to their clearance being so much less, no difficulty will be found in getting the 26in. vacuum required. In this case, however, the air-pump has not to remove the condensing water, hence it may be made much smaller. As, however, the air has still to be extracted as with the jet condenser, we assume that only 20 per cent. of the pump is filled with water. Thus, for a single-acting pump we have, assuming 180 revolutions:

Pounds of water per stroke = 1·11lb.
$= 1{\cdot}11 \times 27{\cdot}6 = 31$ cubic inches (approximate).

$\therefore$ volume swept through by pump bucket = 31 × 5 = 155 cubic inches.

Assuming stroke of 8in., area of barrel = 20 square inches, say.

Hence diameter = about 5in.

A double-acting air-pump is not generally used, but if it were, it need only be half the size as before. The velocity of water through the foot, bucket, and head valves should not be greater than 10ft. per second, and the area of the valves should be proportioned to allow of this being done. The weight of the valves should be as small as possible, for it is evident that the air-pump cannot reduce the pressure in the condenser below that necessary to lift the valves.—T. SQUARE.

Answer to No. 478 (*awarded* 7*s.* 6*d.*).—The formulæ used in designing air-pumps are more empirical than theoretical. The majority of them express the volume of the air-pump in terms of the volume of the low-pressure cylinder or cylinders of the plant in connection with which they are to work, and although many of these formulæ give good working results when applied to the air-pumps of marine and slow-speed Corliss engines, they require modification when used in the design of air-pumps for dealing with the exhaust of quick-revolution engines. Other formulæ, again, connect the volume of the air-pump with the indicated horse-power of the plant under consideration, but two different types of engines may deliver into the condenser steam varying widely in temperature and weight, although the indicated horse-power of both may be the same. The details of air-pump design require very careful attention after the volume and water velocities have been decided, otherwise very moderate results will be achieved.

Referring to the case of the vertical single-acting air-pump in Fig. 1 to be used in connection with a jet condenser, this air-pump is required to pump into the hot-well 12,000lb. of condensed steam per hour, together with the amount of water required to condense it, and the accompanying volume of air. Suppose that the steam is exhausted at a pressure of 6lb. absolute, the corresponding temperature being 170deg. F. = t_1, the initial temperature of the injection water is, taking the higher of the two figures given, 75deg. F. = t_2. A vacuum of 26in. has to be maintained in the condenser, corresponding to a temperature of, say, 124deg. F. = t_3. Now, the amount of heat absorbed by the injection water in condensing 1lb. of this steam

$$= t_1 + \text{latent heat} - t_3.$$

By Regnault $= 1,114{\cdot}4 + {\cdot}3\,t_1 - t_3.$

But heat absorbed may also be written

$$W\,(t_3 - t_2),$$

where W = weight in pounds of injection required for every pound of steam condensed.

$$\therefore W\,(t_3 - t_2) = 1,114{\cdot}4 + {\cdot}3\,t_1 - t_3.$$

$$\therefore W = \frac{1,114{\cdot}4 + {\cdot}3\,t_1 - t_3}{t_3 - t_2} \text{ lb.}$$

Substituting actual values,

$$W = \frac{1,114{\cdot}4\ ({\cdot}03 \times 170) - 124}{124 - 75} \text{ lb.}$$

$$= \frac{1,041{\cdot}4}{49} = \text{(approximate) } 21\text{lb.}$$

$\therefore$ Weight of water to be discharged by air-pump
$= (21 + 1)$ 12,000lb. per hour,
$= 4,400$lb. per minute,
$= \frac{4,400}{62{\cdot}4} = \text{(say) } 70$ cubic feet per minute.

Now, ordinary sea-water contains $\frac{1}{20}$ of its volume of air at atmospheric pressure, which on entering the condenser will be expanded to $\frac{1}{2}^5$ its original volume; and the volume of the mixture to be pumped out every minute after the air has been raised to the temperature of the condenser

$$= 70\left(\frac{19}{20} + \frac{15}{40} \times \frac{t_3 + 461}{t_2 + 461}\right) \text{ cubic feet}$$

$= 94{\cdot}5$ cubic feet.

If the air-pump were a perfect pump, this volume would have to be displaced every minute by the bucket, but the efficiency of a single-acting vertical pump of this type is only about ·5, so that the volume to be displaced by the bucket per minute = (94·5 × 2) = 189 cubic feet. Now, the mean velocity of the mixture of air and water through the bucket valves should be about 480ft. per minute, and as it will be difficult to obtain more than 30 per cent. of the bucket area for the passage of water, the diameter of the bucket will be

Digitized by Google

$$\sqrt{\frac{189 \times 100 \times 144}{480 \times 30 \times 7854}} \text{ inches}$$

$$= 15\tfrac{1}{2} \text{in.}$$

The ratio $\frac{\text{diameter}}{\text{stroke}}$ is decided in the figure; in any case, it only remains to decide upon either the length of stroke or the number of strokes per minute, and the remaining term will be fixed by volume, to be displaced per minute.

With regard to the double-acting air-pump, if the efficiency given by it were the same as that obtained by the single-acting type, it would only be necessary to make the double-acting pump half of the capacity given above, but the efficiency of the double-acting air-pump seldom exceeds ¼, so that its capacity will be determined accordingly. In either pump, if D = diameter of pump and S = speed in feet per minute,

$$\text{Area through foot valve} = \frac{D^2 \times S}{1{,}000} \text{ square inches;}$$

$$\text{,, ,, head valve} = \frac{D^2 \times S}{800} \text{ square inches.}$$

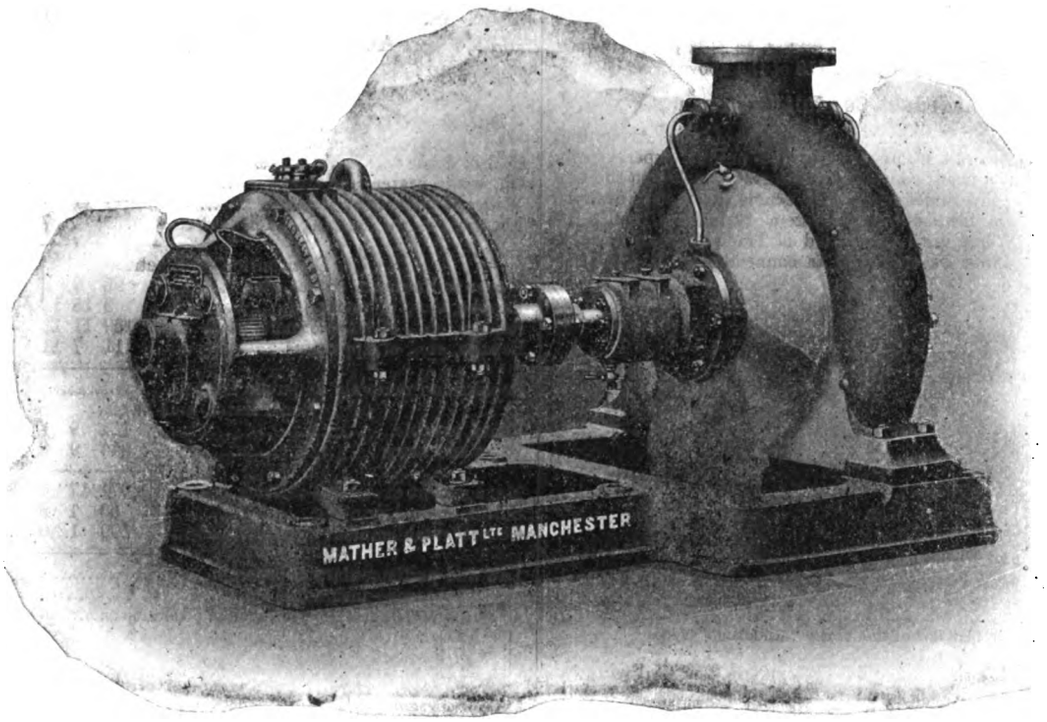
If the area through the foot valve be excessive, its action is liable to be sluggish, and the efficiency of the pump correspondingly decreased. The capacity of a jet condenser should be from ¼ to ⅓ the volume of the cylinder or cylinders exhausting into it, the latter figure being for use with quick-revolution engines.

With regard to the cooling surface required in surface condensers, with the terminal pressure assumed at the commencement—viz., 6lb. absolute—1·8 square feet per indicated horse-power will suffice with the cooling water at 75deg. F. It is generally regarded as a very satisfactory performance if one square foot of cooling surface will condense 13lb. of steam per hour. In conclusion, the design shown in Fig. 1 is hardly in accordance with the best modern practice.—C. L. B.

TRADE NOTICES AND NOVELTIES.

Electric High-Lift Pump.

Messrs. Mather and Platt, of Manchester, while standing in the front rank as pioneers in electrical engineering, have an equally good reputation in a considerable number of other branches of engineering manufacturing. Amongst the more recent of their productions is a high-lift pump driven by electric motors. Up to the present most of the mine pumps made for working against a considerable head have been of the slow-moving plunger type. Even then the shocks due to the reversal of the slow-moving plungers causes considerable wear and tear of the plant. Messrs. Mather and Platt have taken up the design of a multiple-chamber centrifugal pump, which is specially adapted for high lifts. The pumps are manufactured under the Mather-Reynolds patent. The feature of this pump is that it consists of one or more sets of vanes, or impellers, each set running in its own chamber, but upon a common shaft, the delivery pressure of the liquid varying directly as the number of chambers used. Thus, if an ordinary single pump can deliver water against a head of 30ft., the addition of another chamber will give a final delivery head of 60ft., while four chambers will enable the pump to discharge the same amount of water against a head of 120ft. With this multiple pump the firm have been able to deliver large quantities of water to a height of as much as 150ft., a result never attained before by a centrifugal pump. Recently they have introduced still greater improvements, and are now able to deliver water against as great a head as 200ft. with a single chamber, and at a high efficiency, some of the larger sizes giving out the equivalent of as much as 76 per cent. of the power put into them. In our illustration we give a view of one of these pumps, which have given great satisfaction in several installations. In one case in a Spanish silver mine they have been at work since July, 1888, delivering 1,000 gallons of water per minute against a head of practically 1,500ft. In this instance there are three sets of pumps in series, each capable of working against a head of 500ft. The pumps are placed up the shaft at 500ft. intervals. In this way the lowest pump draws directly out of the sump and discharges straight into the suction pipe of the pump 500ft. above, no lodgment for water being necessary; the middle pump in like manner, drawing direct from the first, delivers straight into the third or top pump, so that the column of water is entirely unbroken, and constantly flowing steadily onward. The result is manifest in the now continuous working of the pumping plant, the cessation of breakdowns, and practically the disappearance of the former vast bill for repairs and maintenance. Two or three times a year the pumps are stopped, the internal parts pulled out, examined, cleaned, and replaced, and the plant set to work again after the incredibly short stoppage of about four hours. The pumps are driven by direct-coupled motors, which are supplied with current from the surface, the old hydraulic engines having been altered so as to drive electric generators by belt from the flywheel. It is interesting to learn that the present electrical and pumping plant is run with 15 per cent. less coal than was used by the best of the former pumps; and not only that, but the coal now used includes what is required to generate steam for other purposes, such as for electric lighting and for keeping the spare steam dynamos warmed up ready for starting in case of a breakdown in the generating plant.



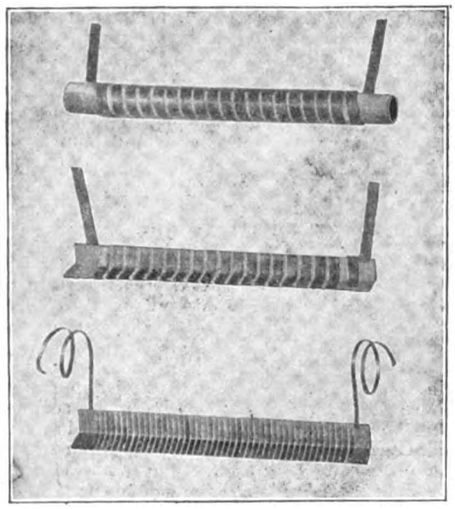
Mather and Platt High-Lift Centrifugal Electric Pump.

Field Rheostats.

The design of resistance coils has for years been an intricate problem with which electrical engineers have had a considerable amount of trouble. A good rheostat should be able to dissipate heat without danger to itself or to the surrounding apparatus. The British Thomson-Houston Company have standardised a type of field rheostat resistance which overcomes the many objections which exist in older forms. We refer to their packed card resistances, of which we give an illustration herewith. This form consists of a series of resistances built up in the following way: A tube of asbestos on a steel mandrel is wound with a definite amount of German-silver wire or ribbon, taken from the mandrel, and pressed into the card form shown. These cards are the unit resistances used in making the rheostats. They are assembled side by side with asbestos between successive cards, the number of cards depending upon the resistance required in the rheostat. To increase the radiating surface, iron plates somewhat wider than the cards are inserted at intervals between the resistances, and project beyond the

Digitized by Google

surface of the resistance section. The resistance cards and iron plates are then clamped by end plates and bolts. For heavier work, such as for the rheostats used in connection with railway motors, the British



Wound Tube and Pressed Cards for the British Thomson-Houston Rheostats.

Thomson-Houston Company still use spiral resistances supported between slabs of slate. Engineers interested in this class of work would do well to get the pamphlet No. 118 of the above firm.

The Armorduct Conduit System.

Mr. Fred Bathurst, the general manager of the Armorduct Improved Electric Conduit Company, has had unique experience in conduit work, and as a result considerable interest attaches to the new system which he is now introducing. Of course, he is still desirous of getting the single insulated wire system introduced, using the conduits as a return, but until the Board of Trade allow an earth in every house this cannot be employed in connection with a central-

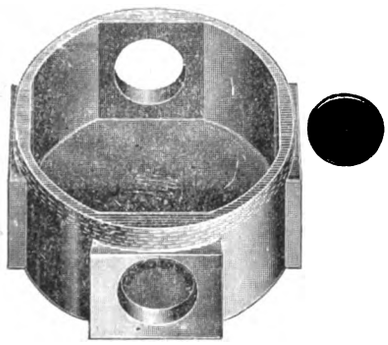


FIG. 1.—Circular Box of the Armor "Knockout" Type.

station supply. With the Armorduct system two insulated wires can be drawn into the same tube, and in certain cases the screw joint between the tubes and the boxes is dispensed with, as could not be done with the single insulated wire. The Armorduct itself is a high-grade mild-steel welded tube, with a specially smooth interior. The tubes are carefully coated both inside and out with a flexible moisture-proof enamel, which preserves the metal. We are also informed that the tubes can be easily bent cold without damaging it. As a rule the tubes will be supplied with a conduit thread, but they can be worked also with the ordinary gas thread if desired. So much for the tubing itself, and we now come to the boxes, which are of the "knock-out" type. This term

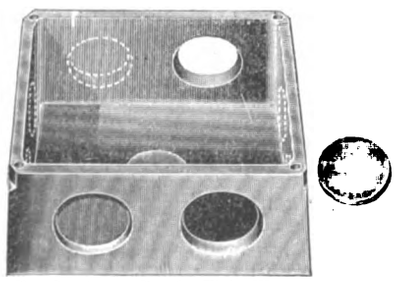

FIG. 2.—Square Box for Eight Ways.

has other significance than a high quality in this case. The boxes are supplied without any holes for the tubes, but there are in the sides of the box recesses cast in with a thin piece left as a seal, which can be knocked out with a smart blow from a hammer. Two of these boxes are shown in Figs. 1 and 2, in which this feature can be clearly seen. In connection with these boxes, which permits of these holes being knocked out as required on the job, the company have standardised a series of nuts (Fig. 3) which enable the tubes to be secured into the boxes without tapping the same. In especially damp places, however, the holes in the boxes can be screwed to give an absolutely water-tight joint, or an extra lock-nut can be added to the tube and a watertight joint secured by means of a packing between this and the square face on the box. In the illustration (Fig. 2) a

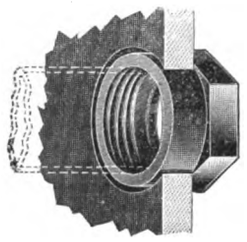

FIG. 3.—Conduit End applied to Side of Box.

square box is used in which no less than eight holes can be made if required. These square boxes will be found extremely useful where switching facilities are required for two or more separate circuits. The other details of the Armorduct system are also well designed, and the company should find a good demand for their wares.

HASTINGS ELECTRICITY ACCOUNTS.

From the accounts of the Hastings Corporation electricity works department it appears that the total expenditure on capital account to Dec. 31, 1901, amounted to £123,405. Abstracts of the revenue account, etc., are appended:

SOUTH SHIELDS ELECTRICITY WORKS.

The borough electrical engineer (Mr. J. H. Cawthra) in his first annual report to the Electric Lighting Committee points out that the first three months of the year under review were under the management of his predecessor. The capital expenditure has increased £10,312, bringing up the total amount spent to £138,801. Of this increase the sum of £6,450 has been laid out on new mains and some slight additions to the sub-stations, £536 on meters and other apparatus for consumers' premises, £2,811 being retention money held over on various contracts for new engines, alternators, boilers, pipework, etc. The kilowatt capacity of the plant installed at the depôt is the same as 12 months ago, and quite sufficient to meet all our requirements for some two or three years, probably more. The lamps connected have risen from 35,025 to 41,680, being an increase of 6,655, equivalent to 19 per cent.; whilst the consumers connected have increased from 680 to 778, this being an increase of 14 per cent. The maximum load on the station at any one time during the past winter was on Jan. 25, when the load was 767 kw., being an increase of 62 kw. over the previous year at the rate of 8 per cent., and the total maximum load is equal to the use of 25,566 8-c.p. lamps for the time being, this maximum load taking only some 48 per cent. of the normal capacity of the station. The number of units sold was 985,646, being an increase over the previous year of 229,820, equivalent to some 30 per cent. The public lighting has developed somewhat, the total number of arc lamps being practically the same, whilst the number of ordinary gas standards which have been converted to electric brings the total up to 283, being an increase of 175 since March, 1901. Coming to the revenue-earning side of the department, this appears at first sight somewhat disappointing, but on closely investigating the varied circumstances under which the department has worked during the two years forming the subject under review, the financial result is very satisfactory. The total costs chargeable against revenue amount to £5,914, being a decrease of £21 on the previous year, whilst, as before pointed out, the number of units sold equal an increase of 30 per cent. The total revenue amounts to £13,664, against £12,196 of the previous year, being an increase of £1,468, which leaves a gross profit of £7,750 against £6,261, which equals an increase of some 24 per cent., whilst the percentage of gross profit to the total capital expenditure is 5½ per cent., compared with 4·8 per cent. of the previous year. The amount required for interest and sinking fund is £7,155, against £4,793, an increase of 49 per cent. This is accounted for by reason of the readjustment of the sinking funds debited to the year ending March 31, 1901. After meeting all charges, including interest and sinking fund, there is a net profit of £594 against £1,468, being a decrease of £874, which drop will be readily understood in view of the foregoing explanation. From the amount of £594 shown as the net profit on the electric light undertaking must be deducted the sum of £163, being the loss on the working of the Holborn Quay during the past year. It must not be forgotten that during this past year the charge for electrical energy has been at the rate of 7d. and 2d. per unit during the two winter quarters, whereas during the previous year the charge was 7d. and 3d. for the last quarter of the financial year, this usually being the quarter from which the greatest amount of revenue is obtained, and therefore is in itself no small item; and, also, the fact must be taken into consideration that the quarter was made to extend over a period of some 16 weeks by not reading the meters until the financial year had actually expired, thereby reducing the first quarter of the succeeding year by some three weeks, accompanied by a corresponding decrease in the revenue. Mr. Cawthra calls attention to the exceedingly cheap rate at which current has been sold during the past 12 months. The average price obtained per unit for current supplied to private consumers works out at 3·9d. per unit against 4d. of the previous year, being a decrease of some 2·5 per cent.; whilst the price obtained for street-lighting is 1·3d. per unit against 1·8d. of the previous year, which is a decrease of some 28 per cent. The past year has been one comparatively free from breakdowns so far as the generating plant is concerned, not one single interruption in the supply having occurred. Regarding the mains department, he cannot report so favourably; from the commencement of the winter until the end of March there was considerable trouble on the distributors, the same constantly breaking down to earth. The King-street arc main also gave considerable trouble; this main was, however, found to be unfit for further use, and has been renewed. So far as possible, having regard to the limited time at his disposal, the whole of the plant has been maintained in a highly efficient manner, and will, he hopes, by the coming winter have been thoroughly and completely overhauled. Coming to the "cost of production," he calls attention to the greatly reduced cost of generation, etc., the actual cost of producing the energy sold being 1·29d. per unit, against 1·71d. of the previous 12 months, which is equal to a decrease in the working expenses of 24 per cent., this figure being absolutely the lowest cost of production now recorded by any electricity supply works, either municipalities or companies, who generate electricity for lighting purposes only—that is, works which do not enjoy the benefit of a tramway load. Two comparative tables follow, and, in conclusion, Mr. Cawthra states that the total costs per unit sold, including interest and redemption charges, amounted to 3·03d., against 3·23d. of the previous year.

WIGAN ELECTRICITY WORKS.

In his first annual report to the Electric Lighting, Power, and Tramways Committee of the Wigan Corporation, the borough electrical and tramways engineer (Mr. H. Collings Bishop) says: "Generally, I think you may feel that you have had a very successful year. The first few years are always a trying time in electrical works, the difficulties met with being very great. There are always a number of prejudices to overcome, and many other points to prevent the progress being as rapid as desired. Taking everything into consideration, the progress made has been exceedingly satisfactory, and I am also glad to be able to say that all my estimates have come out very close with the result obtained. I have now more data to go upon, so that I hope the estimates I now make for the current year will be even closer than those made for the past. The whole of the works in my charge have been efficiently kept in repair out of revenue, and the plant has been running throughout without any stoppage of supply. The applications in hand for new connections are very much greater than at the corresponding time of last year, and there is every prospect of a very busy time before the staff. I am very much indebted to Mr. Dewse for the large amount of data I am able to include in this report; he has now got the books in excellent condition, and we shall from now on be able to give you every month a statement of all costs and revenue for the preceding month. With regard to the capital expenditure on the electrical plant, the estimates that I placed before you in 1899 have not been exceeded, and in some cases a large amount of work has been executed beyond that mentioned in my estimates. I feel that I should impress upon you the necessity of always keeping a sufficient amount of spare plant in hand to allow for increased demand, and I would draw your attention to the difficulties of Manchester through not doing so."

A number of tables are appended to the report, from which we take the following details: total passengers carried, 1,907,244; total revenue from fares, £8,771. 10s. 1d.; total car miles, 195,969·5; average price paid per passenger, 1·1d.; number of cars in service, 18; passengers carried per car, 105,958; revenue per car, £487. 6s. 1d.; average car miles per car, 1,887; total revenue per car mile, 10·74d.; total length of track in operation, five miles one chain; revenue obtained per mile of track, £1,764; total passengers carried per mile track, 381,448. The total number of lamps connected at the end of the year amounted to 33,889, while the brake horse-power of motors connected to mains was 622½, and the maximum load demanded 453 kw. In a table giving a comparative results of total costs between Wigan and 19 other stations (above and below), Wigan is thirteenth on the list with a total cost of 1·679d. per unit sold, the average price obtained being 2·57d. for private lighting and 2·00d. for traction.

LEGAL INTELLIGENCE.

DUBLIN TRAMWAYS.

In the King's Bench Division of the Four Courts, Dublin, last week, Mr. Justice Johnson and Mr. Justice Kenny had before them the case of the Dublin United Tramways Company *v.* the British Thomson-Houston Company.

Mr. D. B. Sullivan, K.C., who, with Mr. Mahony, appeared for the defendants, said the action was brought to recover £10,500 for breach of agreement. Before an appearance was entered the defendants served a notice of motion to set aside the service of the writ as irregular. That notice of motion was duly served, and appeared in the list that morning. The previous night notice of discontinuance of the action was served by the plaintiffs, and counsel now wanted an order that their costs might be taxed.

The Court granted the order.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Shanghai.—The last day for receiving tenders for the proposed municipal tramway and motor 'bus service is June 30.

Beckenham.—The Electric Lighting Committee invite tenders for the supply of incandescent lamps. Tenders by June 6.

Dudley.—The Electric Lighting Committee invite tenders for the supply of incandescent lamps and oil. Tenders by June 6.

Poplar.—The Electricity Committee invite tenders for the supply of about 130 cast-iron arc lamp columns. Tenders by May 28.

Sophia (Bulgaria).—The General Post Office require tenders for £2,000 worth of telephone and telegraph material. Tenders by June 9.

Poplar.—The Electricity Committee invite tenders for the supply of special armoured cable, suitable for laying under water. Tenders by May 28.

Glamorgan.—Tenders are invited for wiring and fittings at Parc Gwyllt and Angelton Asylums, near Bridgend, Glamorgan. Tenders by May 31.

Calarashi-Stirbein (Roumania).—The Municipality invite tenders for the installation and working of electric lighting for 35 years. Tenders by June 13.

Fulham.—The Board of Guardians invite tenders for the supply, delivery, and erection on their premises of pipework. Tenders by June 5. See advertisement.

Greenock.—The Corporation invite tenders for the supply and erection of one 300-kw. steam dynamo, with steam and exhaust piping. Tenders by June 2. See advertisement.

Valparaiso.—The Municipality are inviting tenders for electric lighting and tramways. We understand that particulars may be obtained from the Chilian Consul. Tenders by Sept. 1.

Bury.—The Tramways Committee invite tenders for the supply and delivery of rails and fishplates, fishbolts and nuts, tiebars, points and crossings, and sole or anchor plates. Tenders by June 24.

Hull.—The Corporation invite tenders for the supply of 20,000 cast-iron holding-down plates (weight, about 42 tons). Full particulars may be obtained at the City Engineer's Office. Tenders by May 30.

Barking.—The Urban District Council invite tenders for motors, pipework, chequer plating, etc. Full particulars may be obtained from the Engineer, Electricity Works, East Barking. Tenders by June 6.

Brighton.—The Town Council invite tenders for the supply of 300 tons of steel girder tramrails. Specifications, etc., may be obtained from Mr. Thos. B. Holliday, tramways engineer, Lewes-road, Brighton. Tenders by June 9.

Lisbon.—The Portuguese Government Railway require 34,300 kilos of 1, 2, 3, and 4 mm. galvanised wire. Tenders by June 9 noon. Further particulars may be obtained from the Company's office, 28, Rue de Châteaudun, Paris.

Glasgow.—The Corporation invite tenders for one economiser, with induced-draught fan, and condensing plant. Particulars may be obtained from Mr. W. A. Chamen, the engineer, 75, Waterloo-street, Glasgow. Tenders by June 7.

Coventry.—The Electric Light Committee invite tenders for the supply and erection of steam and water pipes and accessories. Particulars may be obtained from the Electrical Engineer's Office, Electricity Works, Coventry. Tenders by May 26.

Burton-upon-Trent.—The Corporation invite tenders for the supply and erection of three 100-kw. high-speed tramway generators and switchboard, and three Lancashire boilers, steam-pipes, jet condensing plant, economiser, and accessories. Tenders by May 30.

West Ham.—The Corporation invite tenders for the construction of about eight miles of route length of tramways. Specifications, etc., may be obtained from the offices of Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster. Tenders by June 10.

Brighton.—The Town Council invite tenders for the supply of points, crossings, tiebars, bolts, and other fittings. Specifications, etc., may be obtained on application at the office of Mr. Thos. B.

Digitized by Google

Holliday, tramways engineer, Lewes-road, Brighton. Tenders by June 9.

Launceston (Tasmania).—The Corporation invite tenders for polyphase generating, transmitting, and distributing plant and apparatus, transforming apparatus, reconstruction of existing plant, and enclosed arc lamps and accessories. Tenders by Sept. 15. See advertisement.

Manchester.—The Tramways Committee invite tenders for the supply of cast-iron bases, collars, and finials for tramway poles; and tramway rail bonds. Specification, etc., may be obtained from Mr. J. M. M'Elroy, general manager, Tramways Department, 55, Piccadilly, Manchester. Tenders by May 24.

Govan.—The Council invite tenders for fuse boxes for house services, meters (not electrolytic), demand indicators, manhole boxes and connections, and joint-boxes for armoured cables. Particulars may be obtained from Mr. J. Brown, resident electrical engineer, Electricity Works, Govan. Tenders by May 27.

Stretford.—The District Council invite tenders for the following in connection with its scheme for supply of electrical energy: Steam-raising plant, comprising boilers, superheaters, economisers, etc.; generators, comprising engines, dynamos, condensers, pumps, etc.; and mains. Tenders by June 18. See advertisement.

Astrachan.—Erection of electric generating station and installation of public and private lighting, commencing with 150 arc and 6,000 incandescent lamps. Manufacturers who will undertake to finish the work within two years can obtain particulars from the Municipality. Agents will not be able to tender. Tenders by June 7-20.

Bury.—The Tramways Committee invite tenders for the work required in the construction of the permanent way in several parts of the borough—viz.: Fairfield section, Bolton-road section, Heywood-street and Knowsley-street sections. Specifications, etc., can be obtained on application at the office of Mr. Arthur W. Bradley, borough engineer and surveyor. Tenders by June 24.

Worthing.—The Corporation invite tenders for the supply and erection of one 250-kw. steam dynamo (continuous-current dynamo direct-coupled to a vertical enclosed high-speed engine), and one dry-back marine type boiler, with fittings. The specifications, etc., can be inspected and all information obtained at the offices of Messrs. Burstall and Monkhouse, 14, Old Queen-street, Westminster, S.W. Tenders by May 26.

Belfast.—The Harbour Commissioners invite tenders and designs for the decoration and illumination by electricity or otherwise of the harbour office and the south end of the Glasgow shed, Donegall Quay, in connection with the celebration of the coronation of King Edward VII. A detailed specification of the work proposed to be carried out must accompany each tender. Any further information required may be obtained from the harbour engineer, Mr. G. F. L. Giles. Tender by June 2.

RESULTS OF TENDERS.

Mansfield.—The Electricity Committee have accepted the tender of Crompton and Co. for pipework, at £2,486.

Insulating Compound.—The National Telephone Company have accepted the tender of Rowland Carr and Co. for the supply of insulating compound for the six months ending Dec. 31, 1902.

Limerick.—The Allgemeine Elektricitäts-Gesellschaft, contractors for the electric lighting of Limerick, have accepted the tender of Messrs. Rowland Carr and Co. for the arc lamp columns required.

Brighton.—The Tramways Committee have accepted the tender of J. Longley and Co., Crawley, for extension of the car-sheds, boundary walls, and certain other buildings at the tramway depôt, Lewes-road, at £4,849.

Willesden.—The District Council have accepted the tender of the British Insulated Wire Company for the supply and erection of arc lamp columns of the design and manufacture of R. Carr and Co., London, E.C.

Lowestoft.—The Town Council have accepted the tender of J. Abbott and Co. for extra pipework in connection with the condenser, at £249. 10s., and that of Geipel and Lange for two feeder switch-boards for the harbour crossing, at £110.

Swindon.—The Corporation have accepted the tender of W. T. Glover and Co., Trafford Park, Manchester, for the supply, delivery, and laying in the borough of Swindon (Wilts) of feeder and distributing cables, conduits, and accessories, at £5,411.

East Sussex.—The County Council have accepted the tender of J. E. Spagnoletti and Co., of London, amounting to £11,773. 11s. 2d., for electric light and power plant, and £1,940 for the tramways, in connection with the provision of electric light and power plant, and for electric energy for the tramway.

Edinburgh.—The Electric Lighting Committee have accepted the tender of Crompton and Co. for the supply of carbons for continuous-current arc lamps for the year from May 15, at the following prices: 18mm. by 12mm. 12in. long, £4. 11s. 2d. per 1,000 pairs; 22mm. by 15mm 12in. long, £6. 13s. 7d. per 1,000 pairs.

Rotherham.—The Electric Light and Tramways Committee have accepted the following tenders in respect of Contracts 9, 10, and 11 for tramways: (Contract No. 9) rolling stock, Dick, Kerr, and Co., London, £8,711; (10) overhead construction, Macartney, McElroy, and Co., London, £7,102; (11) permanent way, Macartney, McElroy, and Co., £55,419.

Southampton.—The Tramways Committee have received the following tenders for the laying of the proposed tramways in St. Denys-road: Douglas and Richards, £4,666 (accepted); F. Grace, £4,733; G. Wimpey and Co., London, £4,841; W. Griffith and Co., London, £4,905. 16s. 7d.; F. Osman, £5,160. 7s. 1d.; Coston and Co., £5,208; Saunders and Saunders, Birmingham, £7,178. 4s. Borough engineer's protecting tender, £5,000.

Southend.—The Town Council have accepted the following tenders: Norman Engineering Company, East Dulwich, for electric wiring; H. Morris and Bastert, Loughborough, crane, £135; R. Blackwell and Co., London, car-lifting appliance, £35; Rawlinson and Sons, Blackburn, tower wagon, £60; British Thomson-Houston Company, five feeder motors £8. 18s. each; D. King and Sons, Glasgow, 50 arc lamp columns at £8. 10s. each; Crompton and Co., testing machines, £92. 10s.

Wolverhampton.—The Corporation have accepted the following tenders for the supply and delivery of the machine tools, etc., necessary for the complete equipment of the repair shops at their tramcar depot: Dempster, Moore, and Co., Robertson-street, Glasgow, one 12½in. centre sliding, surfacing, and screw-cutting lathe with continuous box gap, complete with 12in. chuck boring tools, motor, gearing, fixed and delivered complete, £228; one hydraulic wheel press, complete with 6in. pressure gauge, £69. 10s.; one radial drilling machine, complete with drills, drill chuck, and motor complete, £140; one set plate-bending rolls, £34.

Alternators.—The British Schuckert Electric Company, Limited, have recently received several contracts for alternating-current work—including two 600-kw. two-phase generators for the Corporation of Coventry; one three-phase generator and two three-phase motors for the Oakbank Oil Company; two three-phase generators and three three-phase motors for the Lancashire and Yorkshire Railway Company. Messrs. Browett, Lindley, and Co., Limited, have received the order from the Bournemouth and Poole Electricity Company for two 1,000-kw. steam alternators, complete with condensers and accessories. The engines are to be of the three-crank triple-expansion type, running at a speed of 250 revolutions per minute, and the alternators are to be made by Messrs. Ferranti Limited, of Hollinwood.

London.—The London School Board have received the following tenders for electric lighting at Northwold-road New School:

Vaughan and Brown	£489	0	0
Comyn Ching and Co.	412	10	0
Drake and Gorham	392	0	0
D. Watson and Co.	372	15	0
Lund Bros. and Co.	368	0	0
Rashleigh Phipps and Co.	368	0	0
Marshall and Woods	322	0	0
Wells and Co.	314	0	0
J. C. Christie*	310	0	0

* Recommended for acceptance.

Glasgow.—The Parish Council have received the following tenders for the electric wiring at the new general hospital, Stobhill:

C. Hamilton, Limited, 247, St. Vincent-street, Glasgow (accepted)	£4,197
Middleton and Townsend, 21, Rutland-square, Edinburgh	4,511
J. M'Kenzie and Co., 64, South Woodside-road, Glasgow	4,685
McCulloch, Potter, and Co., 127, West Regent-street, Glasgow	4,948
J. Findley and Co., 12, Renfrew-street, Glasgow	5,356
Cook and Gilchrist, 4, Norfolk-street, Newcastle	5,419
Casselle and Co., 168A, St. Vincent-street, Glasgow	5,580
Anderson and Munro, 136, Bothwell-street, Glasgow	5,989
Reid and Co., 57, Hope-street, Glasgow	5,670
Lowden Bros., 332, Argyle-street, Glasgow	6,138
McAuley, Clark, and McLellan, 34, Ann-street, Glasgow	6,273
Osborne and Hunter, 93, Waterloo-street, Glasgow	6,850
McAlpine's Electrical Company, 60, Bath-street, Glasgow	6,691
Malcolm and Allan, 29, Lilybank-road, Glasgow	6,750

Paisley.—The Corporation have received the following tenders in connection with the Paisley and District Tramways Company's proposals: For converting the 600-kw. alternator in terms of Mr. Parkinson's scheme—Bruce Peebles, £2,100; with delivery in seven months; Siemens Bros. and Co., £2,350, with delivery in seven months; Crompton and Co., £2,455, with delivery not given; British Schuckert Co., £1,984, with delivery in four months (accepted); British Thomson-Houston Co., £2,670, with delivery in six months. Messrs. Siemens, Crompton, and British Thomson-Houston Co. did not include the flywheel. The following tenders for supply of alternating plant, were also received: Hick-Hargreaves, engine £1,750; alternator £1,830, speed 200; Belliss and Morcom, engine £2,070, alternator £1,600, speed 250; Davey, Paxman, and Co., engine £1,450, alternator £1,612. 5s., speed 300 (accepted); Willans and Robinson, engine £2,137, alternator £1,570, speed 300; Ferranti, engine £1,760, alternator £1,600, speed 250; Siemens, alternator, £1,035; British Schuckert Co., alternator, £935. For alterations and additions to the Adamson engine—Adamson and Co., £268, with £40 additional for packing (accepted). For supply of motor-generator—British Schuckert Company, £1,210, with switchboard £130 (accepted). For alterations and extensions of the condensing plant—Korting Bros., £1,642 (accepted).

Wireless Telegraphy Monopoly. — The German Government propose to invite all the maritime powers, but in the first instance Great Britain, France, and the U.S.A., to a congress in order to come to an agreement which would prevent any monopoly in wireless telegraphy. This is stated to be a direct outcome of the action of the Marconi station at the Nantucket lightship during the recent visit of Prince Henry of Prussia. When it became known that certain messages originated from the "Deutschland," which is fitted with the Arco-Slaby instruments, the Marconi station refused to accept or transmit the message. Various letters have recently been published in a number of papers in Germany and France, as well as in England and the U.S.A., in which Prof. Slaby and Marconi make several contradictory statements, amongst which we note that Marconi says that the synchronising of his instrument prevents the reception of messages from instruments of other makes, while Slaby says that his instruments may be synchronised for Marconi's instruments.

BUSINESS NOTES.

TRACTION.

Cleethorpes.—The authorised speed of the tramcars is to be reduced from 12 to 10 miles an hour.

Glasgow.—It is expected that the municipal tramway receipts will show a surplus this year of £100,000.

Rotherham.—The Town Council have accepted tenders in connection with the tramway scheme amounting to £72,000.

Fylde.—The Rural District Council have passed a resolution in favour of the proposed Preston and Lytham light railway.

Lancaster.—It is hoped to have the electric cars running in July, rapid progress having been made with the construction of the new lines.

Rawtenstall.—The Town Council have approved the heads of agreement with the company who are promoting the Rossendale Valley Tramways Bill.

Portsmouth.—The Corporation have retained Mr. Rotter as their consulting engineer for the tramways, and a new general manager is to be appointed.

Plymouth.—It was stated at the last meeting of the Borough Council that the Beaumont section of the tramways was not likely to be a financial success.

Clacton.—The Light Railway Commissioners have granted the application of the Clacton-on-Sea and St. Osyth Light Railway Company for an order.

Wilpshire.—The tramway extension to Wilpshire having been inspected by Major Druitt, of the Board of Trade, was last week opened for passenger traffic.

Prestwich.—The Urban District Council and the Manchester Corporation have come to terms with regard to the working of the tramway system in the district.

Nottingham.—The Mapperley section of the Corporation electric tramway system was opened last week. This is the fifth route which has been inaugurated up to the present.

Ramsgate.—The local Bench have inflicted a fine of £5 on the Isle of Thanet Electric Tramway Company for running their cars at an excessive speed—*i.e.*, 16 miles an hour.

Byker.—An electric watering-car has arrived at the car-sheds here, and is being fitted up. The travelling tank is of a capacity sufficient to carry several thousand gallons of water.

Swindon.—Application is to be made by the Town Council for an extension of time for 12 months in which to complete the tramways authorised by the Corporation order of 1901.

Maidstone.—The Rural District Council have decided that they cannot consent to the construction of a light railway between Maidstone and Barming as proposed by the Corporation.

Stalybridge.—At a meeting of the Stalybridge, Hyde, Mossley, and Dukinfield Tramways and Electricity Board last week plans were approved of the track construction in connection with the proposed tramways.

Barrowford.—A Sub-Light Railway Committee of the Urban District Council have been appointed, with power to make all necessary arrangements for the carrying into effect of the Council's light railway order.

Mansfield.—The Town Council are in communication with the promoters of the light railways as to when they are likely to commence their work. The Corporation have gone in for an expensive plant to supply the cars with electricity.

Rochdale.—The Bury-road section of the new electric tramways, which are in course of construction by the Rochdale Corporation, was opened for traffic yesterday, the Board of Trade inspection having taken place the previous Thursday.

Aberdeen.—A plumber was working at the electric tramway depôt last Saturday last when he accidentally caught hold of a live electric wire. The shock rendered him unconscious, and he only survived an hour after being taken to the hospital.

Institution of Electrical Engineers.—At the annual general meeting of the members of the above Institution last night, the house list for the session 1902-3, which will be found in our issue of 25th ult., was adopted without amendment.

Bradford.—Mr. James Hill, chairman of the Tramways Committee of the Corporation, and Mr. C. J. Spencer, manager of the city tramways, have returned to Bradford from their American trip, which was undertaken in order to see present-day tramway practice in America.

Hastings.—Last week the Town Council rescinded their resolution noted in these columns by which they declined to consent to the promotion of a Bill by a company for powers to construct tramways in Hastings. The whole matter is thus opened up for further discussion.

Common Council.—Replying to a question at the last meeting of this body, the Remembrancer stated that protective clauses to safeguard the interests of property owners along the line of route were being inserted in all the Bills before Parliament for the construction of tube railways.

Dundee.—The Fairmuir electric tramway is now so far completed that a service of cars is being run from Albert-square to the burgh boundary. The double line of rails is laid all the way except a short piece between Arklay-street and Main-street, but it is intended to use the one line at that place.

Rochester.—The City Council have decided to make application to the Light Railway Commissioners next November for an order authorising the construction of a system of light railways within the city boundaries. The Chatham Corporation have agreed to confer with Rochester as to the advisability of establishing a joint scheme.

Thornaby.—At the last meeting of the Town Council attention was called to the necessity for an improved guard to the tramcars, and it was explained that the tramways company had promised to adopt any improved system of guard which might be suggested and found practicable, but as yet none had been suggested to them.

Gloucester.—The Rural District Council have passed a resolution approving the scheme for a light railway between the Gloucester city boundary and Brockworth, and expressing the hope that the County and City Councils will agree to some practicable scheme. The Corporation intend to formally apply to the Light Railway Commissioners for an order this month.

Leicester.—The Corporation Bill came as an unopposed measure before Lord Morley's Committee one day last week. The object of the Bill is to construct tramways and make other improvements, the estimated cost of the whole being £424,356. Formal proof having been given, the Bill was allowed to pass the committee stage, and was ordered to be reported for third reading.

Scarborough.—On Thursday further Standing Order proofs relating to the Scarborough Tramways Bill were submitted to Mr. Jenne, one of the examiners of private Bills of the House of Commons. The proofs being satisfactory, the examiner ordered the measure to be reported to the House of Lords for second reading. The Bill has already passed all the stages of the House of Commons.

Yarmouth.—By the end of the present week everything will be ready at the power station for the supply of current to the tramways. The track has now only to be laid along the North Quay to the Vauxhall railway station. If the points and crossings are delivered as expected, the work will be completed within a month. Ten cars have arrived and the remainder are to be delivered within a week.

Fleetwood.—A new accumulator house has been established by the Blackpool and Fleetwood Tramroad Company between Bispham and Fleetwood. In this building are 250 cells, with a capacity three times greater than those at the Bispham generating station. The batteries are controlled by a Highfield booster. The electrical equipment has been installed by the Chloride Storage Battery Company.

Pontypridd.—A Bill to confirm certain provisional orders came before the Examiner of Bills in the House of Lords for proof of compliance with Standing Orders last week, when an order authorising the Pontypridd Urban District Council to construct additional tramways in their district was ordered to be reported for second reading, proof of compliance with the Standing Orders of the House having been given

Halifax.—A proposal is before the Town Council to proceed forthwith with the construction of the tramway extension from King Cross by way of the Pye Nest-road to Sowerby Bridge. The important question of dealing with parcels traffic by the Halifax tramways system is about to come to the front. A special committee have just been appointed to go into the question with a view to inaugurating a service.

South Shields.—At a special meeting of the Town Council at the end of last week the tramway question was fully discussed. Eventually a motion was agreed to in favour of promoting a Bill in the next session for powers to provide "an adequate scheme of tramways for the borough." A committee was afterwards appointed to settle routes, gauge, system of traction, and other preliminary details, and to report thereon.

Proposed Monorail in Scotland.—It is announced that Mr. Behr is preparing plans for a railway on the monorail principle between Glasgow and Edinburgh, and a start has been made with the survey preparatory to the promotion of a Bill in Parliament next session. The promoters of the scheme are negotiating with the North British Railway Company with a view to the measure being supported by that company.

Pontefract.—A Bill to confirm certain provisional orders which came before the Examiner of Bills in the House of Lords last week contained an order authorising the West Riding Tramways and Electricity Supply Company to construct tramways in the borough and rural district of Pontefract and the urban district of Knottingley. Standing Orders being complied with, the Bill was sent for second reading in the House of Lords.

Manchester-Liverpool Express Railway.—The *Liverpool Courier* announces the Board of Trade have given their sanction to the Manchester and Liverpool Electric Express Railway Company to proceed with the construction of the line, and it is expected that a start will be made next month at three points—Warrington and the opening country just outside the suburbs of Liverpool at one end, and outside the suburbs of Manchester at the other.

Berlin High-Speed Trials.—A note in one of the daily papers says that the high-speed experiments on the Berlin-Zossen Electric Railway are to be resumed shortly. It may be remembered that the special car was expected to reach speeds of 130 miles an hour, and even more. As a matter of fact the highest speed attained was 100 miles, and this only for a short time. The permanent way is now being improved, and heavier rails are being laid on suitable sleepers placed close to one another.

Clydebank.—A sub-committee of the Glasgow Corporation's Tramways Committee have met a representative committee of the Clydebank Town Council in conference on the question of the extension of the city electric lines to that burgh. The Glasgow extension lines are already well forward towards the boundaries of Clydebank. The Town Council of Clydebank already hold a provisional order of their own for tramway construction, and the main questions of the situation refer to the terms on which that order should be handed over to Glasgow.

Hammersmith.—After several interviews with the agents representing the London County Council concerning the proposed tramway

Digitized by Google

in Queen-street, it has been agreed with the Borough Council that the County Council will widen, at their own expense, the carriageway of Queen-street between Bridge-road and the northern boundary wall of the parish churchyard to 60ft. The County Council will also be prepared to continue the widening by taking a strip off the eastern side of the churchyard, provided it can obtain the necessary consents, and conditionally upon the Borough Council assisting in obtaining the consents and contributing one-third the cost thereof.

Madrid.—Extensions are shortly to be made of certain street car lines, and other lines are contemplating a change from mule power to electricity. The Tramway Company of Seville have obtained authority to apply electric traction on a new piece of the "Parque" line from the Avenue of Maria Luisa by the riding ground of Las Delicias to the Venta de Eritana. An application has been made by Don José Batlle y Hernandez for a concession for a system of electric tramways from Sevilla—one to San Juan de Aznalfarache, another from Castilleja to la Cuesta y Sines, and another from Camas to Santiponce.

Electrical Mail Vans.—At 8.20 on Tuesday morning the new electrical mail van started its daily run from Mount-pleasant with a special delivery of mails to Waterloo. This is the first occasion that an English-built electrical motorvan has been used for this purpose, and the postal authorities are now giving this new system an extended trial in the City and West-end services. After considerable tests the authorities have selected one of the Carl Oppermann's electric delivery vans made in Clerkenwell for this service, the motive power being furnished by a set of the "A. B. C." accumulators (Oppermann patent). The contractors for the van were Messrs. Julius Harvey and Co., of Queen Victoria-street.

Edinburgh.—The dispute between the town and the tramway company has at last been finally adjusted. The points in the agreement are first that all litigation against the company be dropped. This will permit of the cars running on Sunday. Secondly, the company agree to pay the arrears of rent and interest to Martinmas last in full. Thirdly, the half-year's rent to Whitsunday should be fixed at £35,000. The fourth clause dealing with the sliding scale of rent contains a number of sub-clauses, the chief being that payment of any interest in unpaid rent may be spread over a period, but the balance is to bear interest at 3 per cent. All claims by the company against the Corporation are withdrawn.

Walsall.—The Tramways Committee report that the South Staffordshire Tramways (Lessee) Company have fixed a number of ½d. stages for scholars and children, and have reduced the tram fares from The Bridge to Wednesbury and to Darlaston from 3d. to 2d. The Board of Trade have approved of the anchor joint being substituted for the Dicker joint in the tramways proposed to be laid by the Corporation. The question of purchasing 28 new cars has been deferred until the spring of next year, with a view to advantage being taken of the latest improvements. Instructions have been given to the town clerk to apply to the Board of Trade to inspect the tramway transformer station in Hospital-street and the cables in connection therewith as soon as the works are completed.

Railway Automobiles.—The United States Consul at Rouen, in a recent report, states that railway automobiles are beginning to be considerably used in Europe: (1) as early and late postal trains; (2) on branch lines and others where passengers are few; (3) on trunk lines where it is often difficult to secure convenient secondary trains; (4) in industrial centres and city suburbs. Furthermore, the automobile railway train can be attached for a certain distance to an express and detached at the station where the road branches. There is an economy in the *personnel* of the train, and in the expense of traction, in material, capital, and maintenance, and an additional traffic because of the increased number of stations made possible by the facility of stopping and starting. Up to the present time the carriages constructed are steam and electric.

Barton Bridge.—At the last monthly meeting of the Davyhulme Parochial Committee, plans were submitted of a proposal for the construction of a system of tramways which will connect Barton Bridge with Glossop. It is intended to promote the scheme in the next session of Parliament. After leaving Barton, where it is proposed to connect with the Trafford Park tramways, the line will proceed to Davyhulme and Urmston, and crossing the River Mersey by a bridge will enter Sale. The tramways will also cover the following places: Northenden, Cheadle and Gatley, Bramhall, Poynton, Hazel Grove, Marple, Ludworth, Chisworth, Charlesworth, Broadbottom, Mottram, and Glossop. The Davyhulme Parochial Committee offered no objection to the proposed tramways, but the plans are to be submitted to the Parish Council for acceptance.

Hampstead.—Protests continue to be raised in this district against the proposed extension beneath the heath to Golder's Green of the Hampstead Heath, Euston, and Charing Cross Tube Railway, which has been passed by the House of Lords Committee. The objections to the tube passing under the heath may be stated as follows: (1) No underground railway should be allowed to go under London's open spaces for fear of spoiling the vegetation by draining off the soil, and for fear of disfiguring their beauties by the erection of stations, ventilating shafts, etc. In this case the promoters have promised that there should be no station on the heath. (2) The readiness of people to subscribe for open spaces will be less than it is if the open spaces are to run the risk of being spoilt as soon as secured. (3) The object of tube railways should be to tap centres of population.

Wolverhampton.—The deadlock between the Corporation and the British Electric Traction Company with reference to tramway communication with Bilston and Willenhall continues. The whole difficulty arises over a short piece of track, about a quarter of a mile in length, which still remains unconstructed. The Corporation will not do the work, and the British Electric Traction Company contend that they cannot undertake it until a mutual arrangement is arrived at. While this edifying controversy is going on the townships mentioned above are totally deprived of any through communication with Wolverhampton, which they ought to have had months ago. It is time that the Corporation awoke to the fact that prompt action is necessary, and if they will not make the few hundred yards of tramway in question themselves, they should at least allow the company to undertake the work.

Leeds.—Amongst the provisional orders included in a confirmatory Bill considered by the examiner in the House of Lords on Friday was one authorising the Corporation to construct additional tramways. The examiner, finding that the Standing Orders of the House had been complied with, sent the Bill for second reading. The latest extension of the city tramways is a circular route between the existing termini at Chapeltown and Roundhay by way of Moortown. This line has been in course of construction for the last two months, and the work has been pushed forward as rapidly as possible with a view to running cars on at least a section of it by the Whitsuntide holidays. The western portion between Chapeltown and Street-lane was completed about a fortnight ago, and the overhead equipment has been supplied for this section in the meantime. Part of the route was open for traffic on Whit Monday.

Motorcars in Burma.—The French Consul at Rangoon has forwarded to his Government some interesting information on the subject of the importation of motorcars into Burma. He says that the great obstacle in the way of importing the cars into that country is to be found in the impossibility of securing essence of petrol of the density of 680deg., which is usually required for such motors. The only essence which could be manufactured on the spot from oil found in Burma attained at best a density of 760deg. to 770deg., no lower degree being obtainable from this raw material. Ordinary petrol, steam, alcohol, or electric motors are, therefore, the only ones that can satisfactorily be employed in Burma. The consul especially recommends the import of voiturettes, and reminds the manufacturers that the duty is 5 per cent. *ad. valorem*, and that no special license is required for driving an automobile in Burma.

Tramway Track Work.—We have received from Messrs. Askham Bros. and Wilson, Limited, Yorkshire Steel and Engineering Works, Sheffield, a very fully illustrated pamphlet describing tramway junctions, cross-overs, lay-outs, depôt sidings, etc., constructed by the firm for a large number of municipal authorities, etc., in various parts of the country. We are informed that five acres of floor space have been specially equipped at the Sheffield works for the construction of this class of track work. Besides views of the works, premises, and the various construction shops, some good examples are shown of intricate sections of tramway cross-overs and junctions which have been constructed by the firm, including those at Farnworth, Sheffield, Leeds, Grimsby, West Hartlepool, Nottingham, Huddersfield, Halifax, etc. An interesting sketch map shows the extent of the firm's operations in connection with the tramway and light railway work of the kingdom.

Cardiff.—The whole of the tramway track in Cardiff has now been reconstructed, and the overhead equipment is making rapid progress towards completion. Horse-car traffic has been resumed on the Bute-road route to the docks, and it is probable that electric traction will be commenced on this route in a fortnight or three weeks. The Board of Trade inspector was to have visited Cardiff this week, but a letter received has intimated that he could not come. He will, however, be in the South Wales district at an early date, and will then make the final inspection of the Cardiff system. The Sunday cars will probably commence running a week hence. Whit Monday proved an unusually profitable day for the new electric cars. No less than 103,000 passengers were conveyed from one part of the town to another—the total receipts amounting to £429 odd. This sum is nearly three times the ordinary day's takings, and almost twice as much as was taken last Whitsuntide, when horse traction was in vogue.

Cheltenham.—At the end of last week the Light Railway Commissioners (the Earl of Jersey, Colonel Boughey, and Mr. H. A. Steward) held a local enquiry into the application of the Cheltenham and District Light Railway Company for powers to extend their light railway to Charlton Kings and to Leckhampton. The case for the promoters was that the extensions were necessary to connect the districts mentioned, which were really suburbs of the town, with the centre and business parts of Cheltenham and with the Midland station at Lansdown. As to the outlying districts themselves, a number of witnesses both from Charlton Kings and Leckhampton gave evidence in favour of the extensions, and largely signed memorials from both parishes to a like effect were also put in. After hearing counsel on both sides, Lord Jersey announced that the Commissioners had decided to recommend the Board of Trade to issue the order as asked for, subject to the elimination of the portion of the High-street route between Cambray and Bath-road.

Birkenhead.—In moving the Tramways Committee's minutes at the last meeting of the Town Council Dr. Pearson said that they had not yet been able to get the actual figures made up with regard to the first year's working of the electric trams, but the net profit would be something over £5,000 after paying all charges, interest and sinking fund, and depreciation. Of course, it was not yet possible to absolutely estimate the depreciation of a tramway electrical undertaking, so that it was proposed to pay the £5,000 into a reserve fund, which would certainly more than cover everything. He pointed out that only one line—New Ferry—had had a full year's working; Conway-street, Higher Tranmere, and Claughton-road had been running seven months; Prenton and Shrewsbury-road five months; and Docks Station three months. On last year's basis they might look for a very big increase on that £5,000 next year. The Tramways Committee recommend the borrowing of £3,700 for the erection of tramway offices at the Laird-street depôt.

London County Council Tramways.—Last week Mr. H. Hobhouse's Committee of the House of Commons further considered

Digitized by Google

the London County Council's Tramways and Improvements Bill, the portion immediately dealt with being that authorising the widening of Hampstead-road at its Tottenham Court-road end, so as to give a width between the walls of the houses of 80ft. A proviso in the Bill stated, however, that the widening should not be commenced until the St. Pancras Borough Council had sanctioned the introduction of a Bill for the continuation of the line of tramways, at present terminating in the Hampstead-road, along Tottenham Co rt-road to Oxford-street. The Chairman announced that the committee were agreed that the proviso must go out. It would tend to prejudice the question of the tramway next year, and the County Council would have full discretion to carry out the widening or not as they chose. The preamble having been found proved, the clauses were adjusted, and the Bill, as amended, was ordered to be reported to the House.

Wigan.—Major Druitt on Friday inspected the extensions of the Corporation electric tramways to Boar's Head, New Springs, Martland Mill Bridge, and Frog-lane, and, after travelling over the various lines, sanctioned the opening of the new services. The first annual report of Mr. H. Collings Bishop, the borough electrical engineer, just issued, gives interesting details of the working of the Corporation tramway system during the past year. The total revenue from this source has amounted to £8,771. 10s. 1d., which works out at 10·61d. per car mile. The expenditure has been 9·83d. per car mile, including sinking fund and interest 3·24d., wages 3·18·l., traffic expenses, comprising current, management, etc., 3·41d., leaving a profit of ·78d. per car mile, representing a sum of £638. 15s. 9d. This has been handed over to the borough fund account. The total number of passengers carried in the year has been 1,907,244, equal to the whole population 31 times over; total revenue from fares, £8,771. 10s. 1d.; total car miles, 195,969·5; average price paid per passenger, 1·1d.; number of cars in service, 18; passengers carried per car, 105,958; revenue per car, £487. 6s. 1d.; average car miles per car, 1,887; total revenue per car mile, 10·74d.; total length of track in operation, five miles one chain; revenue obtained per mile of track, £1.754; total passengers carried per mile track, 381,448. The total capital expenditure amounted to £69,349. 10s. 10d., and the capital expenditure per mile of track open to £13,869. 4s.

Proposed Tramway Combination.—A circular has been issued to the shareholders of the North Metropolitan Tramways Company from which it would appear that the British Electric Traction Company, having come to an agreement with the County Councils of Middlesex and Hertfordshire, is prepared to absorb the first-named undertaking. The Middlesex County Council have already agreed to hand over the greater part of their district on a 30 years' lease to a private undertaking, that in the case of the Hertfordshire County Council being of 12 years longer duration. The lines which have been authorised, or for which applications for authorisation are pending, include the greater portion of North and North-East Middlesex, with some parts of Hertfordshire; and the promoters have recognised that the new system would be incomplete without such a "feeder" as would be supplied by the lines of the North Metropolitan Company, hence the offer which has been made to the shareholders in this company to exchange their holdings. The proposition is one which directly affects the London County Council, who already own the bulk of the North Metropolitan lines, and in eight years' time the lease which the company now holds will expire. If in 1910 the Council are in the same mind as at present that lease will not be renewed, and the traffic will be worked direct. But in the meantime the Council have deposited its plans for the electrification of all the lines, and this will have to be carried out in any case. All that the proposed new arrangement would secure would be the lines in Hornsey, Tottenham, and Edmonton, which are purchasable in 1905, the unexpired lease of eight years, and the plant and rolling-stock of the old company.

Swansea.—On Friday last the Earl of Jersey, Colonel Boughey, and Mr. H. A. Steward, Light Railway Commissioners, held an enquiry into the application of the Glamorgan County Council for power to construct light railways from the Swansea borough boundary at Morriston to Pontardawe. Mr. Littler, for the promoters, said the application was to construct two railways, but they were continuous, and only divided for the purpose of convenience. He recalled the fact that in 1899 the British Electric Traction Company applied for similar powers, but were opposed by the Swansea Corporation and the Glamorgan County Council, and did not succeed. The railway would run from Morriston along the highway, where a very considerable number of steel, tinplate, and chemical works and collieries were situated. Recently Swansea had been extending in the direction of Pontardawe, beyond which there was Ystalyfera. It was not at present proposed to carry the line beyond Pontardawe, because the County Council did not consider it would be wise to do so as yet. The line would be 5¾ miles in length, and the estimate of its cost was £38,010, with £6,110 for overhead equipment and £3,860 for feeders. The number of cars required for a quarter-hour service on weekdays and a half-hour service on Sundays was eight. Taking these at £600 each, and £2,000 for stabling, gave a total capital expenditure in round figures of £55,000. The South Wales Electrical Power Company were prepared to enter into a lease and pay a rent which would at least cover the interest and sinking fund, and there would be an arrangement by which the County Council would share in the profits, and although terms had not been completely arranged as yet, he could assure the Commissioners that the line would not cost the county anything. The Earl of Jersey, at the conclusion of the evidence, said the Commissioners had decided to recommend the Board of Trade to grant the necessary order. The objection of the Swansea Corporation to the repeal of part of their order of 1901 will be settled through the Board of Trade.

Blackpool.—The borough treasurer's report of the past year's working of the municipal tramways shows a deficiency of actual profit below estimate of £4,562. The income amounted to £41,817, as against expenditure amounting to £28,259, leaving a gross profit of £13,558. Against this gross profit there were charges amounting to £10,079, leaving a disposable profit of £3,479. The estimated profit was £8,041, so that on this estimate the actual result is somewhat disappointing. From the £4,562 below estimate, however, must be deducted £1,723, the excess expenditure over loan on conversion of Promenade route from conduit to overhead system, as this item was not taken into account in the estimates, so that had this amount not been charged against the year's revenue, the disposable profit would have been £5,202, as against an estimate of £8,041, or a difference of £2,831. The total capital outlay is £214,099. 10s., towards the redemption of which there is accumulated the sum of £16,725. The total of the reserve fund is £2,778, of which £2,500 is invested on mortgage of realty, and the balance is in the hands of the Corporation's bankers. Under Section 57 of Blackpool Improvement Act, 1901, the Corporation may provide out of revenue a reserve fund, if they think fit, by setting aside out of revenue such sum as they may from time to time think reasonable. Such fund may be accumulated until it amounts to one-fifth of the aggregate capital expenditure on the undertaking. The reserve fund already accumulated amounts to about 1¾ per cent. on the capital outlay to March 31, 1901, but the amount carried to the fund has not, says the report, been based upon any well-defined principle; rather has it been determined by the contingency of available surplus profits. The treasurer suggests that the committee consider this question of depreciation with a view of arriving at a rate of percentage of amortisation of the capital assets commensurate with the life of the different classes of capital expenditure. Out of this sum should be provided the sinking fund for redemption of the loan debt, the balance being carried to "reserve." The advantages of forming a substantial and scientific reserve fund, he says in conclusion, are too obvious for comment.

LIGHTING AND GENERAL.

Oban.—The sites for arc lamp-posts have been selected.

Stalybridge.—Active steps are being taken to procure sites for transformer stations.

Chatham.—The question of appointing an electrical engineer has been referred back to committee.

Redruth.—The agreement between the electric lighting company and the Council has been sealed.

Londonderry.—Specifications are being prepared preparatory to an application for sanction to a loan of £35,000 for electric lighting.

Edinburgh.—The Town Council have agreed to the electric lighting of Causewayside from Grange-road to Mayfield Free Church at a cost of £104.

Burton.—A number of extensions of electric light mains will be made, which, according to reports, promise to be very profitable to the department.

Guildford.—The proposal of the Town Council to purchase the works of the Guildford Electricity Supply Company, Limited, has been abandoned.

Callender's Cable and Construction Co.—The directors have resolved to pay a further interim dividend of 10s. per share on shares 1 to 30,000 in respect of 1901.

Lytham.—The *Blackpool Times* says if Lytham must have the electric light, they may do far worse than obtain it "in bulk" from St. Annes; or arrange a joint scheme.

Beckenham.—Mr. Cairns has resigned his seat on the Electric Lighting Committee, and the vacancy has been filled by Mr. Blake. Mr. London has been elected chairman and Mr. Mann deputy chairman.

Bangor.—The electrical engineer (Mr. Price White) in his last report states that 25,823 units of electricity had been sold during the March quarter, an increase of 7,026 units as compared with the corresponding quarter last year.

Stock Exchange.—Application has been made to the Stock Exchange Committee to appoint a special settling day in Marconi's Wireless Telegraph Company's further issue of 7,264 shares of £1 each, fully paid, Nos. 149,820 to 157,083.

London Gazette.—A first and final dividend of 2s. 1¼d. per £ has been declared in the estate of R. Foster and W. Baker (trading as R. Foster and Co. and the Nelson Electrical Engineering Company), Scott-street, Nelson; payable at official receiver's office, 14, Chapel-street, Preston, from May 27.

Margate.—Questions were asked at the last meeting of the Town Council respecting the introduction of electric lighting for the streets. It was stated that at present there was no possibility of electric light being utilised, as the Corporation could not come to terms with the Isle of Thanet Electric Light Company.

Groenock.—For the five weeks ended May 3 36,594 units of electricity have been generated for lighting, and 29,640 units sold, and 67,437 units have been supplied for traction. In consequence of a report by Mr. W. M. Nelson, engineer, regarding the necessity of providing additional generating machinery to meet the probable demand during next winter, the Council have agreed that the engineer be instructed to prepare a specification for a 300-kw. generating set, and advertise for offers.

Sale of Plant.—The Electric Lighting Committee of the Leyton Urban District Council, having adopted steam plant of much larger units, are prepared to sell a number of gas-engines, Dowson gas generators, and accessories, the whole forming a complete plant capable of supplying electricity to a small district, and certain engines, dynamos, and gas generators taken together will make suitable sets of plant for factories. The plant is sold as in good working order, and may be inspected on application at the works. Offers for the whole or parts will be considered, and must be sent in by June 25 next.

Digitized by Google

Surbiton.—The Council have obtained the formal sanction to the borrowing of the £50,000 required for the electric lighting, and have sealed the agreement with Messrs. Callender.

Stonehaven.—The Town Council are corresponding with Messrs. Barlow and Young, who propose to apply to the Local Government Board for an electric lighting order for Stonehaven.

Bridgwater.—The Town Council have consented to the application of the Bridgwater and District Electric Supply and Traction Company, subject to clauses being agreed to, for a provisional order for electric supply for lighting and power purposes.

Kensington.—The Borough Council are purchasing from the Brompton and Kensington Electricity Supply Company the seven electric arc lamps and columns erected by them on the south side of Kensington High-street at £24. 10s. per column.

Competition.—As a sequence to the promise made by Signor Pini two years ago at the Como Volta Festival, the Agricultural Society of Lombardy offers now a prize of 1,500 lire (£60) for the best essay on the influence of electricity upon vegetation, and especially agricultural produce.

Nuneaton.—The Urban District Council are taking steps to raise the sum of £5,000 (by two instalments of £3,000 and £2,000) required in connection with the electric undertaking. It is proposed to commence with laying of cables in Manor Court-road and the lighting of that portion of the town.

Radcliffe.—Messrs. W. Allen, Hardman, Lund, Slingsby, and Yates have been appointed by the District Council a Works Sub-Committee to consider matters relative to the position, construction, and the general arrangement of the buildings and machinery required for the electricity undertaking.

Burnley.—The Rural District Council are canvassing the ratepayers within the area to be included in the suggested application to the Board of Trade for a provisional electric lighting order with a view to ascertain the number of persons likely to use electric light in the event of the Council being able to supply the same.

Islington.—Extension of mains are to be made as follows (subject to the London County Council's sanction to loan): Sunnyside-road section, £1,723; Warltersville-road section, £2,016; Hornsey-lane section, £2,730; sub-station and fittings, £661; Highbury-terrace, £252; Liverpool-road, £190; City-road, £330.

Electric Launches.—An international exhibition of motor launches will be held at Wannsee, Berlin, next month. Particulars may be obtained from the Secretary-General, Berlin Universitätstrasse.—The King is having a new summer house built at Virginia Water and also a slip for the electric launch he is about to place upon the lake.

Canals.—A proposal is on foot to introduce steel barges to be worked by electricity on the Birmingham and Worcester Canal. This will also probable involve the widening and deepening of the Severn and the Birmingham and Worcester Canal, so as to form a continuous water route for vessels of 300 tons burden from the Midland metropolis to the sea.

St. Paul's Cathedral.—The electric installation is now complete. The choir pendants were first used at Easter; the dome and the nave were also lighted for the first time with electricity on Whit Monday. Under the dome handsome new pendants, suspended from brackes fixed near the arcs of the quarter-domes, have been put up during the last few days.

Nernst Lamps.—We have received from the Electrical Company, Limited, Charing Cross, a new price list for Nernst lamps, type A 1,902. It contains only a few small alterations, but we notice that the company point out that to ensure good working the voltage of burner and resistance combined should not be lower than the highest pressure ever received in the mains.

Bolton.—The following reduced scale of charges has been adopted for current for motive power from April 1, 1902: first 500 units per quarter, 2½d. per unit, less 10 per cent. if paid within 21 days; second 500 units, 1½d. per unit, less 10 per cent. if paid within 21 days; all units above this, 1d. per unit net. The price for tramway current has been reduced from 1·5d. to 1·4d. per unit.

Leeds.—We note from the accounts of the Corporation's electric lighting department for the year ending March 25 last, an abstract of which appears in another column, that in comparison with the previous year the revenue has been affected to the extent of about £8,000 by a reduction of prices and the abolition of meter rents. The accounts, however, after providing for interest and sinking fund charges, show a surplus of £3,170. 0s. 2d.

Wireless Telegraphy.—It is stated that Prof. Fessenden's and Mr. Marconi's wireless systems will be installed in Alaska. The first system guarantees 30 words per minute, and supplies two sets of instruments for 13,000dol. Under the latter a guarantee of 12 words over a longer distance is given—viz., 165 miles—and two sets of instruments will be supplied for 22,010dol., with a royalty of 500dol. after the first year and one-half of all commercial earnings.

Cardiff.—Mr. A. Ellis in his last report states that during the last month the voltage generated showed an increase of 32 per cent. on the same month last year, the output 31 per cent. and the revenue 30 per cent. The public and private supply had been well maintained. Permission was given to extend the mains along Tudor-road to the car depôt at Clare-street. The estimated cost was £224, and the engineer thought that there would be a profit on the present basis.

Cults.—Mr. Balfour, of the firm of Messrs. Lowdon Bros. and Co., electrical engineers, Dundee, who has purchased the property of the Cults Electricity Supply Company, has made a thorough inspection of the engines and boilers at Cults, and proposes to put in extra mains at once in order to supply customers who are without the boundary of the present mains. We learn that operations will be commenced immediately the sanction of the court has been obtained to the bargain, this being necessary on account of the sellers being in liquidation.

Hamilton.—At the last meeting of the Town Council the Electric Lighting Committee reported that the price offered by Messrs. Edmundson, London, the contractors for the lighting of the town, for the generating station at Almada Hill, inclusive of buildings, was £32,302. In view of the fact that Messrs. Edmundson had agreed to have the works completed and the light turned on by the end of the year, the committee's recommendation that the agreement be now completed was adopted.

Hammersmith.—Since the last Council meeting 11 additional consumers have been connected, representing a maximum of 307 8-c.p. lamps, and during the same period two consumers have been disconnected, the present number of consumers now taking current from the mains being 1,008. The Council have agreed to the London and North-Western Railway's scheme for the extension of the electric supply mains to the north of the borough, including the laying of a main along Hythe-road.

Personal.—Much interest was centered in a very pretty wedding which took place at St. James's Church, Exeter, on the 15th inst., the building being crowded with spectators. The marriage was between Mr. Harold Rippon, electrical engineer and contractor, of Exeter, and Miss Miriam Adelaide Stevenson, eldest daughter of Mr. C. H. Stevenson, of the same city. Amongst the many serviceable and handsome wedding presents we note a silver cigarette case to the bridegroom from his employés.

Maidstone.—The Urban District Council's Electric Light Committee state in their last report that the following lamps have been applied for and connected: number of consumers who have applied, 128; number of consumers connected, 101; total current applied for in 8-c.p. lamps equivalent 14,727, made up as follows: private lights, 8,217; motors. 5,730; public 780—total 14,727; total lamps connected to date 7,576, made up as follows: private, 4,326; motors, 2,530; public, 720—total, 7,576.

Whitehaven.—The following new scale of charges for current supplied for purposes of power is proposed: to consumers using 75 per cent. of their maximum demand for an average of 40 hours per week throughout the quarter, 2d. per unit; to consumers using 75 per cent. of their maximum demand for an average of between 40 and 100 hours per week throughout the quarter, 1½d. per unit; to consumers using 75 per cent. of their maximum demand for an average of over 100 hours per week throughout the quarter, 1d. per unit.

Walsall.—According to the last report of the Electric Lighting Committee, the total number of consumers supplied on April 30 last was 225. During the past month the total units generated at the station was 36,823. The total output from the main generators was 35,383 units. The total units from the transformers was 27,188 (estimated). The machinery was run for 473 hours. The wages paid amount to £90. The tenders for the supply of a battery and booster for the Hospital-street sub-station have been referred to the electrical engineer for report.

Middlesbrough.—The Electrical Lighting Committee last week recommended a reduction in the price for current as follows: for anything up to 250 hours' use of the maximum supply demanded, 2d.; for anything over 250 and under 500 hours' use of the maximum supply, 1¾d.; for anything over 500 and under 750 hours' use of the maximum supply, 1½d.; for anything over 750 and under 1,000 hours' use of the maximum supply, 1¼d.; and for anything over 1,000 hours' use of the maximum supply demanded, 1d. After discussion the matter was referred back.

Aberdeen.—A report is being prepared showing the cost of lighting in all the streets at present lit by gas, and what the estimated cost of the electric light for the same area would be. Four Bremer arc lamps have by way of experiment been erected in Albyn-place under the direction of the city electrical engineer, Mr. J. A. Bell, and so far as they have been tried have given satisfaction. The lamps have been placed at a distance of 80 yards apart, while those in George-street are only 40 yards apart, and those in Union-street, which were the first of their kind to be erected in the city, are 75 yards apart.

American Railroads and Telegraphs.—A Reuter dispatch states that the Pennsylvania Railroad Company has notified the Western Union Telegraph Company that the existing agreement, under which the telegraph company's lines are operated over the Pennsylvania Railroad Company's system, will terminate at the close of six months. The decision is a result of the failure to secure certain concessions from the Western Union Telegraph Company. The railway company's decision, however, will not prevent a renewal of the agreement with the telegraph company should the directors decide that it is advisable.

Australian Telegraph Rates.—The Eastern Extension, Australasia, and China Telegraph Company notifies that a tentative arrangement has been come to with the Federal Government of Australia by which the reduced tariffs now in force in the four contracting States—namely, 3s. per word for ordinary telegrams, 2s. per word for Government telegrams, 1s. per word for Press telegrams—will be applied to the States of Victoria and Queensland pending the negotiations which the Prime Minister (Mr. Barton) proposes to conduct with the company's directors in London for a uniform agreement for the whole Commonwealth. The reduced rates will come into force on 1st prox.

International Cables.—The Association of Chambers of Commerce having urged on the Post Office the establishment of additional and improved cables between the United Kingdom and the Continent, a reply has been received stating that besides the additional cable laid last year to the Netherlands, a new cable to Germany has been laid. These are constructed to yield the best attainable results in practical working. A direct wire has also been opened between Liverpool and

Digitized by Google

Paris. With regard to telephonic communication, a new cable to Belgium has been laid this month, and the negotiations for an extension of the Anglo-French telephone service to the principal towns in both countries have recently been brought to a successful conclusion.

Earl's Court.—Paris in London is already a very attractive show, although the principal electrical wonders, such as the moving spiral way, for instance, are only in the stage of construction as yet. Some of the features of last year have been transformed by means of new paint and new names, and the Chinese dragon has become Le Dragon rouge, and carries its passengers on its accumulator cars as merrily as ever. The trip to Canton has become the River Styx—sticks used to be the word as far as the punts were concerned, and the more they stuck the greater was the fun. The inclined electric stairway is still in use, the moving diorama, the theatrephone, etc. The main show is, of course, the Palais des Costumes—of great artistic value and beauty.

Broadstairs and St. Peter's.—At the last meeting of the Urban District Council a communication was received from the Board of Trade with reference to the Broadstairs electric lighting order, formally transmitting, for the observations of the Council, a description of the system the undertakers proposed to carry out for the supply of energy. It was stated that the Board, with the concurrence of the Postmaster-General, had provisionally approved the proposal of the undertakers to make a connection with earth, on the condition that such connection must be made at one point only—viz., at the generating station. It was notified that this might be at any time revoked by the Board of Trade. The work of laying the cables has been commenced in Albion-street.

Lowestoft.—All places of worship are to be supplied with current at a fixed rate of 6d. per Board of Trade unit. A cable is to be laid from the Grand Hotel to the new Congregational Church at a cost of £45. The resident electrical engineer in his last report states that there are now 11,495 8-cp. lamps connected to the mains, representing 243 consumers, thus giving a total of 310 extra 8-c.p. lamps for the month, representing eight consumers. Applications for about 1,100 lights are in hand. The switchboard house on the south side of the river has been completed to his satisfaction. The town clerk has been directed to look into the policy for the insurance of the workmen under the Workmen's Compensation Act, and in case the outside workmen are not covered thereby, to effect a further insurance for them.

Sudbury.—An enquiry has been held by Mr. H. H. Law into an application by the Corporation for sanction to a loan of £12,000 for electric lighting. The following is the estimate of the capital outlay proposed: purchase of site for electricity works (proportion of cost), £100; proportion of buildings for electricity works, including foundations for generating plant, brickwork for boiler, etc., £850; generating plant, including boiler, steam dynamos, exhaust feed-water heater, pipework, feed pump, battery of accumulators, main switchboard, station lighting, £5,900; underground mains for public and private lighting, including 91 new lamp-posts and lamp brackets, with fittings and connections complete (but not including incandescent lamps), £3,350; house service connections, meters, and cut-outs, £1,000; legal and expert services and contingencies, £800.

Bermondsey.—At the last meeting of the Borough Council the Finance Committee reported that the loans already raised for the electricity and dust-destructor works and flag-making plant, including purchase of land, amount to £33,899. 8s. The Council on Feb. 18 last sanctioned further loans amounting to £31,700, but in order to cover the liabilities already incurred, and to be incurred, it is necessary that an additional loan of £10,300 be raised. They recommended that the loan be applied for, which was agreed to. The Council have accepted the electric lighting order as granted by the Board of Trade. The Board have struck out St. Olave district from the order, and inserted a clause relative to Rotherhithe, providing for the sale of the undertakings of the London Electric Supply Corporation comprised in the parish of Rotherhithe to the Council, should the company desire to sell. The Council in those circumstances would have to pay the company the fair market value of the Rotherhithe part of the company's undertaking as a going concern, the value to be determined, in default of agreement, by arbitration.

The Mordey-Fricker Meter.—This meter, which is being manufactured for the Mordey-Fricker Electricity Meter Company, of 82, Victoria-street, by the British Insulated Wire Company, was on view at the Royal Society conversazione last week. The meter is of the clock type arranged on novel lines, in that the clock only goes when the current is on, and its rate depends on the amount of current which passes. In this way the counter on the clock train serves as a record of the electricity. The hairspring of the clock is replaced by a magnetic control, which consists of a disc of slate in which a number of small needles of iron are embedded. Two coils, through which the current to be measured is passed, embrace this oscillating disc. The proportions of the apparatus are so arranged that the iron is worked on the rising part of the characteristic curve, which is essential to give accurate results. The meter has to be wound by hand. The claim made for this new type of meter is that it is accurate, it is independent of the kind of current supplied, working equally well with direct and alternating currents of any frequency, and last, but not least, that it can be supplied at reasonable rates. We understand that the new company will be introducing a prepayment type of meter in the course of a month or two.

Birmingham.—The Electric Supply Committee of the City Council on Friday issued their report giving the financial results of the working of the department during the year ended March 31 last. The units sold during the year, as compared with the previous year, were as follows: 1902—3,391,099 units, £61,384. 4s. 4d.; 1901—3,040,822 units, £55,810. 4s. 2d., being an increase of 11·5 per cent. in units sold, and 9·9 per cent. in money value. The revenue account shows a gross profit of £18,514. 2s. 9d., and as the charges for interest and sinking fund amount to £23,327. 2s. 3d., the net result is a deficiency of £4,812. 19s. 6d. This is due to the charge of £8,731. 11s. 6d. for the conversion of a portion of the system from 110 to 220 volts with which the revenue account had been debited. This sum, being of the nature of special expenditure, largely increasing the efficiency of the system, might not unreasonably have been charged against the renewal fund, in which case there would have been a gross profit of £27,245. 14s. 3d., and a net profit (after providing for interest and sinking fund) of £3,918. 12s. The change of the system to the higher voltage has been nearly completed, and at the present time there only remains a small district to be dealt with, the cost of which it is estimated will not exceed £3,000.

Spennymoor.—A start has been made at the Northern Counties Electricity Supply Company's large power station. The building has been erected by Messrs. Douglas Bros., of Heaton-on-Tyne, the Callender Cable Company laying the mains. The plant consists of two water-tube boilers, by Messrs. Babcock and Wilcox, fitted up with mechanical chain-grate stokers; two combined three-crank engines, running at 450 revolutions per minute, and giving 350 h.p., supplied by Messrs. W. H. Allen and Son, of Bedford, direct coupled to a 200-kw. machine from Messrs. Crompton and Co. The switchboard was supplied by Messrs. Dorman and Smith, of Salford. There are also two batteries of 250 accumulator cells of R-17 plates, supplied by the Chloride Company, Manchester. On Monday last the engines were set in motion in the presence of a Board of Trade representative, who also tested the cables with about 1,000 volts. In all there are already over 2,000 lamps connected in places of business, and in a large number of workmen's dwelling houses, on the penny-in-the-slot principle, with a guaranteed light for 5½ hours for 1d. for six lights. The first light was switched on on Saturday by Mrs. R. Clark, wife of Mr. R. Clark, of the firm of Clark and Co., electricians, Spennymoor, and everything passed off without the slightest hitch. The company have been invited by the Urban District Council to tender for next season's street lighting.

Wigan.—The electricity generated during the year ended March 31, 1902, totalled 725,043 units. Of this 579,904 were sold, 76,000 were used on the works, and 69,144 were used in distribution and unaccounted for. Of the units sold each successive quarter shows an increase over its predecessor, which is encouraging. At the commencement of the year 11,401 lamps were connected, and these have been augmented by 22,498 during the year, which brings the total at the end of the year to 33,899. The total motors connected to mains number 86. The total capacity of the station is 1,200 kw. The maximum load demanded is 453, to be held as reserve 300, leaving available for fresh connections 447. Four boilers have been installed. Two are in use, one to be held as reserve, and one available for extra demand. We extract from the accountant's report as follows: "Electric revenue—the balance to credit of revenue account is £2,202. 11s. 10d., against a debit balance the previous year of £1,271. 7s. 8d., and the balance to debit of profit and loss account £2,300. 5s. 6d. against a debit balance of £4,221. 1s. 2d. the previous year. The amount expended on motors and fixing same—viz., £5,613. 11s. 3d.—appears in the balance sheet as stock in hand, your committee having decided to capitalise this account as soon as the necessary formulæ have been completed. Electric capital—the total expenditure on this account is £86,312. 2s. 4d., loans outstanding £77,242. 5s. 6d., and loans repaid £2,757. 14s. 6d."

St. Petersburg.—The annual report and balance-sheet of the Eclairage Electrique de St. Petersburg, Limited, has just been issued. During the last year new boilers and plant have been added, bringing the total up to 8,000 h.p. An agreement has been entered into between the three companies supplying the city, which has had the effect that all competition with regard to acquisition of customers from each other has ceased to exist. The length of feeders and cables has increased from 241,846m. in 1900 to 257,624m. in 1901, exclusive of 67,017m. for public lighting; 1,023 transformers, aggregating 9,173 kw., have been installed; the number of meters increased from 2,958 to 4,230, and that of subscribers from 4,287 to 5,340. The lamps connected rose from 183,790 to 217,776 giving with the public lamps a total of 222,741. Amongst the total lamps and motors connected there are over 88 per cent. incandescent and about 5½ per cent. arc lamps, 5·2 per cent. motors and 0·7 per cent. fans, etc.; 85·6 per cent. of these pay by meter. The receipts from all sources amounted to £108,000, against £86,150 in the preceding year. The receipts by meter increased by 34 per cent., and those for motors 54 per cent. The expenses were about £400 less than in the previous year, and came to £72,480. There was a great reduction, about £2,000, in the cost of production, and £1,000 in that of distribution, but new fuses made up for this saving. The cost of production per unit works out as follows: fuel, 1900, 0·9—1901, 0·792; oil and other material, 1900, 0·072—1901, 0·033; salaries and wages at station, 1900, 0·148—1901, 0·120; maintenance and various, 1900, 0·063—1901, 0·071. Total, 1900, 1·183—1901, 1·016. The total of units produced in 1900 was 8,798,342, and in 1901 9,878,815. Without counting the bonus payable on redemption, the 4½ per cent. shares of this company at the present price bring in 6 per cent.

LEEDS ELECTRICITY ACCOUNTS.

From the accounts of the Leeds electric lighting department just received it appears that the total expenditure on capital account up to March 25, 1902, amounts to £505,029. Abstracts of the revenue account and general balance sheet are given herewith.

PROVISIONAL PATENTS, 1902.

MAY 12.

10822. Improvement in or in connection with overhead wires used for electric traction and similar electric installations. Henry Cracknell, John William Cracknell, and Charles Thornes Phillips, 30, Park-row, Leeds.

10826. Improvements relating to clockwork operated electrical switches. Francis Collins, 10, St. George's-crescent, Liverpool.

10837. Improvements in and relating to starting switches for electric motors and the like. Thomas Harrison and George Alexander Smith, 47, Henry Nelson-street, South Shields.

10841. An improved form of insulator for electric fittings. Charles Thomas Arnold Henshaw, 7, Meadowbank-crescent, Jock's Lodge, Edinburgh.

10856. Improvements in switchboards for illuminating electric lamp signs, and cards or tickets for automatically actuating the same. Mortimer Norden, 33, Chancery-lane, London. (Complete specification.)

10881. Improvements in electric incandescent lamps with rare earth filaments. William Alfred Crook and Edward Mines, 6, Lord-street, Liverpool.

10888. Improvements in electromagnetic devices. Luigi Cerebotani and Albert Silbermann, 111, Hatton-garden, London. (Complete specification.)

10889. Improvements in or relating to telephone receivers and transmitters. Walter C. Runge, 111, Hatton-garden London.

10890. Improvements in or relating to telephone systems and apparatus therefor. Walter C. Runge, 111, Hatton-garden, London.

10899. Improvements in electric circuit protecting devices. Sebastian Ziani de Ferranti and Charles Cornfield Garrard, 18, Southampton-buildings, Chancery-lane, London.

MAY 13.

10934. Improvements in arc lamps. Joseph Devonport Finney Andrews and Electrical Productions, Limited, 61, Carey-street, Lincoln's-inn, London.

10938. An improved electric switch. William White, 165, Queen Victoria-street, London. (Friedrich Rohr, Spain.)

10945. Improvements in and relating to electric detonating fuses for blasting and mining purposes. Harold Bonser, 33, Chancery-lane, London.

10952. Improvements in and relating to electric alarms operated by clockwork. Emil Richard Männel, 27, Chancery-lane, London. (Complete specification).

10957. Improvements relating to electricity meters. Friedrich Lux, 45, Southampton-buildings, Chancery-lane, London.

10971. Improvements in or relating to electric arc lamps. Frederick William Le Tall, Westinghouse-building, Norfolk-street, Strand, London. (Hugo Bremer, Germany.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published June 5.

1901.

5172. Electric thermal device for working switches, registering apparatus, and the like. Charlton and Barton.

5427. Manufacture of electric cables and apparatus therefor. Dover.

7629. Secondary batteries. Celestre and Gondrand.

10206. Electric railways and tramways on the surface-contact system. Cruvellier.

10374. Step-by-step telegraphic apparatus. Mordey and Steljes.

10374. Train control systems for electric railways. British Thomson-Houston Company, Limited. (Case.)

11857. Armature windings for dynamo-electric machines. Arnold and Collischonn.

12975. Secondary batteries. Madden. (Date applied for under International Convention, March 19, 1901.)

13182. Manufacture of ornamental vases, bottles, and other ornamental vessels, electric switch caps, and other articles. Deacon, Birkett, and Faulkner.

14237. Electric arc lamps. Girdlestone and Thorkelin.

15155. Conduits for carrying electric conductors. Hirst and Boyes.

15918. Method of electrical distribution for traction Marillier.

17105. Machines for perforating strips of paper for use in telegraphic transmitters, automatic musical instruments, and for other purposes. Wright and Green.

18830. Automatic electric fire-alarm. Brewster.

20384. Variable-pressure electric current transformer. Ritzer. (Date applied for under International Convention, March 11, 1901.)

20561. Feeder or junction box for electric mains. McGillivray and Carr.

24054. Resistances for arc lamps and other electrical apparatus. Davies.

24239. Cases or holders for Nernst lamps. Drake, Sheppard, Ram, and Nernst Electric Light, Limited.

26604. Instruments for recording varying magnetic fields or the currents producing them. Siemens Bros. and Co., Limited. (Siemens und Halske Aktiengesellschaft.)

1902.

1736. Arrangements for controlling and regulating the supply of electricity to medical heating apparatus and the like. Phillips.

5103. Method of and apparatus for connecting the conductors or armour of electric cables and the like to junction boxes, earth-plates, and other parts. Callender's Cable and Construction Company, Limited, and Ward.

5663. Electrical fuse boxes. Waterhouse, and Simplex Steel Conduit Company, Limited.

6229. Electric typewriters. Kochendörfer.

6379. Continuous-burning arc lamp with inclined carbons. Rignon and Eisenmann.

6648. Signal telegraphs. Lavens and Lavens.

7383. Electric arc lamps. Högner.

7851. Electrical sterilising and preserving apparatus. Lake. (Giroux and Seddon.)

7858. Electric vacuum discharge tubes. Krouchkoll.

7898. Conduits. Budd.

7995. Production of metallic deposits by electrolysis. Jensen. (Firm Dr. G. Langbein and Co.)

8667. Method of regulating the pressure of alternating-current dynamo-electric generators. Siemens Bros. and Co., Limited. (Siemens und Halske Actiengesellschaft.)

NOTES.

Acknowledgment.—We beg to acknowledge the current number of *Science Abstracts*, which, as usual, has its full complement of abstracts of current scientific literature.

Faraday House.—Prof. C. A. Carus-Wilson, M.A., M.I.E.E., commenced a special course of lectures to the senior students of the Electrical Standardising, Testing, and Training Institution upon dynamo, motor, and transformer construction on Monday evening last.

Society of Arts.—It is announced that the annual conversazione of the above society will take place at the Royal Botanic Gardens, Regent's Park, on Tuesday, June 24, from 8.30 to 12 p.m. Each member is entitled to a card for himself and lady, and he can also obtain extra cards of admission at his own cost on application to the secretary of the society.

State Laboratories.—We note that a commission of the State of New York has been appointed to consider the question of the establishment of a State electrical laboratory to provide independent authoritative information on questions of electrical science, and an official standardising laboratory for electrical measuring instruments, apparatus, and standards for the protection of municipalities and the general public in the use of electrical energy. The commission is not expected to issue its report till the fall of 1903.

Lectures on Space Telegraphy.—Present lecture arrangements at the East London Technical College, Mile End-road, include two special courses by Mr. J. T. Morris, A.M.I.E.E., on interesting subjects. The first course, consisting of six lectures, deals with the principles involved in wireless telegraphy and their practical applications. This course is very fully illustrated by experiments. The other subject on which Mr. Morris is lecturing at the above college is "Electric Traction Principles and their Application to Electric Railways." A syllabus of the courses may be had on application to the director of studies at the college.

Water Power in Spain.—We hear that it is proposed to utilise a waterfall on the Jarama River, about 11 miles distant from Madrid, to generate electricity for lighting and power purposes in the city. In the first instance about 3,000 h.p. will be developed. It is thought that electrical energy for power purposes would have a large demand in and around Madrid from the considerable number of factories which already exist and others projected in the district. The tramways in the city, also, are expected to be extended very soon, when a change will be made from mule to electric traction, so that the development of electrical power in the neighbourhood is likely to prove a successful enterprise.

Power Transmission in California.—An electrical water-power plant, the largest in the United States, and capable of generating upwards of 300,000 h.p., is about to be laid down in California for the transmission of power to San Francisco, a distance of 175 miles. According to a San Francisco newspaper, the scheme involves the construction of about 10 miles of canal and tunnel in order to obtain a vertical fall of 1,600ft., the water being obtained originally from the Feather River. Recently several water appropriations have been made on the part of the Feather River, with the object of converting 13,000 acres of peat swamp into storage reservoirs, and it is in connection with this work that the above scheme is to be undertaken.

Institution of Junior Engineers.—A large party of the members of the above institution recently paid a visit to the Great Eastern Railway Works at Stratford. In the locomotive machine shop, automatic bolt machines and general machinery for dealing with locomotive work were seen, and large planing machines, etc., were in operation in the erecting shop, where locomotives, both new and repaired, were in various stages of construction; in this shop, also, pneumatic tools were seen tapping and drilling. Pneumatic tools were also at work in the boiler shop, and hydraulic riveters and flanging machines, together with general machinery appertaining to boiler work. The party also visited the locomotive department and the Westinghouse brake shop.

Students' Section.—The report of the hon. secretary, Mr. H. D. Symons, on the work of the above section of the Institution of Electrical Engineers for the session 1901-2, states that 13 meetings have been held during the period. The average attendance of students has been good, and the discussions on the papers have been well maintained. Thirteen works and installations of special interest in the neighbourhood of London have been visited on various Saturdays during the session. Reference is also made in the report to the students' visit to Newcastle at Easter, occupying five days from Tuesday, April 8, to Saturday, April 12, during which time Stockton-on-Tees, Sunderland, and Jarrow, besides other works in Newcastle, were separately visited.

Electric Lighting in East London.—It may be within the memory of some of our readers that some four years ago the County of London and Brush Provincial Electric Lighting Company obtained parliamentary powers to supply electricity in the hamlet of Mile End Old Town, the Limehouse district, and the parish of St. George's-in-the-East. For various reasons the company did not put their powers into effect, and eventually the districts concerned applied for and obtained their own provisional order subject to arrangement with the Brush Company, who, however, claimed as much as £22,000 for the extinction of their rights. The matter was according referred to arbitration, with the result that the arbitrator has reduced this claim by no less than £17,000, and ordered the payment of a sum of £5,000 to the company. This is to be levied on the three parishes and districts named, who will then be free to put their provisional orders into operation.

The Factory Act of 1901.—It was announced in the early part of the week that the President of the Board of Trade has consented to receive a deputation from the Institution of Electrical Engineers on the question of the incidence of the Factory and Workshops Act of 1901 in its application to the generation and sale of electricity in this country. The reception was originally fixed for 12 o'clock noon yesterday, but owing to urgent business Mr. Ritchie has been compelled to postpone the meeting to next Thursday, June 5, at the same hour. It will be understood that the sending of a deputation to the President of the Board of Trade is the direct outcome of the conference of representatives of the electrical industry held the week before last to decide what action should be taken with regard to the framing of regulations for electrical undertakings under the new Factory Act, and the Institution are to be congratulated on having secured an appointment with Mr. Ritchie in so short time.

The Electric Searchlight.—We understand that some practical tests as to the efficiency of the electric searchlight for purposes of coast defence will commence at Sheerness next Monday and continue all next week. Orders have been issued for the mobilisation of a body of troops on that day, who will be responsible for the defences of Sheerness and the Isle of Grain while the electric searchlights at the entrances to the Rivers Thames and Medway, and on Bruntwick Island and the opposite shore, where

Digitized by Google

the Medway boom crosses the river, will be tested. The searchlights will be operated by a detachment of Royal Engineers. Official announcement is further made that the coast defences in the West of England also are being tested this week. The two ports of Plymouth and Falmouth are to sustain an attack by torpedo craft, and the searchlights will consequently be brought into use as in wartime. The efficacy of the electric searchlight to locate these vessels—which will steam at full speed, and without lights—at night time will thus be practically demonstrated.

Royal Meteorological Society.—The first of the afternoon meetings of the session was held on the 21st inst., when Captain D. Wilson-Barker read a report prepared by Mr. W. H. Dines and himself on the wind force experiments which had been made on H.M.S. "Worcester" off Greenhithe and at Stoneness Lighthouse, 817 yards from the ship on the north bank of the river. These experiments were in continuation of those on the exposure of anemometers at different elevations which were carried out on the "Worcester" a few years ago. All the observations were made with the pressure tube anemometer. The broad general result is that the lighthouse experiences steadier and stronger winds than the "Worcester," the velocity being about 6 per cent. greater, notwithstanding the fact that the elevation is less than half, but that in both positions the extreme velocities reached in the gusts are about equal. Dr. H. R. Mill also read a paper on "The Cornish Dust Fall of January, 1902." From a consideration of the meteorological conditions at the time and for several days before, the author is inclined to believe that the evidence points to the dust having been transported in the upper air from the African deserts.

Electric Lighting in South Africa.—Mr. Bennet Burleigh, the able war correspondent of the *Daily Telegraph*, in a lengthy dispatch from South Africa, has some information to give which will be read with interest by electrical engineers. Writing on the recent Boer peace conference, and describing the arrangements made for the reception of the Boer delegates at Vereeniging, Mr. Burleigh says that both electric lighting and water were laid into the camp. The electrical installation consisted of arc and incandescent lights, the former for the open spaces and the latter for the tents. As is well known, most of the mines in South Africa have their own electrical generating plants, and current for the impromptu installation referred to was obtained from this source. The laying on of electric lighting to the temporary encampment erected for the conference is, perhaps, not a great achievement in itself, but it serves to show the progress of electricity as a lighting agent in what is comparatively a new country. Indeed, in New South Africa it is a small and poor village that does not boast of having the electric light, and, as in this particular instance, the current is often obtained in out-of-the-way places from the mines having their own generating plants. It may be recalled that many of the temporary hospitals in South Africa on the veldt and in the towns are lighted by electricity, the installations being similar to that quoted above.

Electrolytic Preparation of Paris Green.—The following interesting and simple method for the preparation on a commercial scale of Paris green, the aceto-arsenite of copper, is proposed by Mr. Richard Franchot, of Niagara Falls: A copper anode is dissolved in a mixed solution of calcium acetate and arsenious acid, whereupon the separation of the insoluble double salt occurs directly. The reaction is strictly anodic, and in order to maintain the separation of the cathode products, the cathode, a sheet of copper, is enclosed in a linen bag, which performs the function of a diaphragm. It is essential that this separation should be complete, since either the hydrate or the hydrogen formed at the cathode would destroy the regular course of the reaction, the former by the precipitation of the corresponding copper compound, and the latter by the reduction of arsenious oxide with liberation of the highly poisonous gas, arsine. It would seem that investigators have not touched upon this field to any extent, though Mr. Franchot's work recalls the method whereby Scheele's green has been produced by the electrolysis of an 8 per cent. solution of sodium sulphate with copper electrodes in the presence of suspended arsenious oxide. In this case the copper is dissolved as a sulphate, and the arsenic as sodium arsenite and the regeneration of the sodium sulphate. Mitis green has also been produced in an analogous manner, the arsenious oxide being replaced by a solution of the pentoxide, which trickles slowly into the bath around the cathode.

Internal Resistance of Galvanic Cells.—A paper by Mr. C. H. Ayres, jun., in which are given the results of an investigation to determine experimentally whether the internal resistance of a cell is a function of the current, is abstracted in the current number of *Science Abstracts*. The method adopted was a modification of that due to Kohlrausch, one of the resistance arms of the bridge being made up of a fixed capacity in series with a variable resistance, and the other arm of a fixed capacity in series with the cell. The remaining arms consist of a slide wire. If a b are the sections of the wire, then for equilibrium we have $r_1/r_2 = a/b = c_2/c_1$. The method of operation is to move the slider until a minimum is found, then vary r_2 (r_1 being supposed fixed) so as to improve the minimum; then move the slider again, and so on. The value of r_2 was found by measurement on a separate Wheatstone bridge. The cell is either on open circuit or shunted with a known resistance as desired. Any capacity effect due to polarisation unites itself with the capacity already in circuit, and thus an error of that kind is avoided. This method determines both capacity and resistance, but the figures given only refer to the latter. Both paper and mica condensers were used, the latter having a capacity of 30 microfarads. Measurements on known resistances showed that the method was accurate to $\frac{1}{2\frac{1}{2}}$ per cent. Upon testing Daniell, Leclanché, and dry cells the author found the resistance was independent of the current. The experimental part of the paper is followed by a theoretical part which shows how the accuracy depends upon the inductance, capacity, and resistance, and upon the frequency of the current.

Modern Induction Coils.—Prof. Trowbridge has a short article in last month's *Philosophical Magazine*, in which he describes a recent development of the induction coil. The high-frequency discharges of a Thomson-Tesla coil are probably the largest sparks yet obtained from any kind of induction coil, but although these may possess enormous voltage, yet the total quantity of power usually obtained from a Thomson-Tesla coil is not very large. Of the primeval induction coils, the Apps inductorium is said to have given a 6ft spark. From an apparatus of the Planté type, in which condensers are discharged n series, but are charged in parallel, the author says he was unable to produce a spark more than 7ft. long. He believes, however, that suitably constructed induction coils may be capable of considerably exceeding this sparking distance. The principal features of the coil used by Prof. Trowbridge are the relative short but powerful primary winding, consisting of a single layer of wire, and

Digitized by Google

a special form of electrolytic interruptor on the Wehnelt principle. These two elements are connected in series across 110-volt mains. A small motor is employed to impress a definite frequency upon the electrolytic interruptor. The current in the primary circuit varies between 5 and 10 amperes, representing, roughly, from ½ kw. to 1 kw. of primary power, with a secondary sparking distance of 30in., at a frequency of from 5,000 to 60,000 interruptions per minute. It is mentioned, however, that the primary current is probably much in excess of the indicated current at the commencement of each cycle of induction. From his experiments in this direction, Prof. Trowbridge deems it possible that by suitable design, developing the electrolytic interruptor in the primary circuit, long sparks liberating many kilowatts of power may soon become available.

New Form of Cavendish Balance.—An interesting study by Mr. G. K. Burgess on a new form of Cavendish balance is abstracted in the current number of the *Electrical Review* of New York. According to this writer, the sensibility of Cavendish's method for the determination of gravitation constants would be much increased if, while still preserving heavy masses hung from the balance arm, the tension which this weight exerts on the suspension wire could be suppressed. This possible, nothing would prevent realising a measurement as sensitive as might be desired. The attraction between the two systems of spheres—the fixed and moving systems—would remain a definite quantity, and allow increasing the deflection of the movable system by reducing more and more the diameter of the torsion wire. With this object in view, the weight of the turning system is compensated by a float immersed in a mercury bath, and capillary action that may tend to hinder the mobility of the system is eliminated, and if the zero remains constant under this condition, an instrument of unlimited sensibility is secured. A length of 12cm. was chosen for the lever arm, and from the ends of the balance arm two lead spheres of 2 kg. each were hung, the whole being buoyed by a cylinder immersed in mercury, whose surface was covered by dilute sulphuric acid; a rod passing through the mercury and acid connects the cylinder to the balance. The points of support for the spheres are below the centre of inertia of the system, giving the balance arm the form of three sides of a rectangle. With this arrangement the torsion fibre has to support a weight of only 5 grm. or 10 grm., which allows of using a fine quartz fibre. Besides a gravimeter, this apparatus might become accidentally both a magnetometer and electrometer, thus introducing sources of error due to magnetic or electrostatic attractions. These effects must be carefully eliminated.

Glass-making in the Electric Furnace.—In the course of an interesting article in the *Electrical World* on the subject of recent developments in electro-chemistry, Mr. C. T. Townsend mentions two patents granted to German inventors which relate to the utilisation of the electric current in the manufacture of glass. The first of these patents, issued to August Voelker, describes a device which both melts the raw material and refines the glass, applying to the former operation the arc and to the latter the resistance principle. The electric furnace chamber devised by Chamatte, surmounted by the reflecting dome, carries electrodes, beneath which the raw material is fed from hoppers. The molten mass overflows into a refining pot, which is constructed with integral perforated partitions. Into the lateral chambers formed by these partitions dip carbon electrodes, between which the circuit is closed by the molten mass. Under the influence of the heat developed the glass becomes fluid and is rapidly cleared from gas bubbles, while the perforated partitions prevent its contamination by fragments from the electrodes. With reference to the current used, the statement is made that it may be assumed that five amperes for each square millimetre of electrode surface is a fair maximum. The other patent referred to was taken out by Johann Zuhne, and describes a rather complicated structure operating on analogous principles. The raw material is melted by passing through a series of arcs, developed between a horizontal prismatic bar of carbon and a series of horizontal electrodes ranged along either side. The central bar is hollow and laterally perforated for the injection of hydrogen to raise the temperature of the belt of arcs. The raw material thus fused flows through a run-way in the base of which are embedded any of the usual Nernst conductors, by the heat of which it is brought into a highly fluid state before it is discharged into the refining pots. This furnace is said to be applicable to the highest grades of optical glass, colourless, and absolutely uniform in structure.

A Wireless Telegraph Tuning Device. — Mr. Marconi now claims to employ in his wireless telegraphy operations a tuning apparatus which makes the messages exchanged between any two stations, or between ship and shore, absolutely secret. It will be remembered that some time ago the possible "tapping" of wireless messages by a third party was one of the principal objections to Mr. Marconi's system, but, as he recently explained in the course of a lecture to a Dundee audience, he has completely overcome this difficulty. As bearing on the point, we understand that an agreement has been entered into between Prof. M. I. Pupin, of Columbia University, U.S.A., and the Marconi Wireless Telegraph Company by which this company obtain the right to the use of a tuning apparatus invented by Prof. Pupin, which is also said to ensure absolute secrecy in the transmission of wireless messages. It is further claimed for this arrangement that it will enable as many as 12 messages to be sent simultaneously between two stations. The apparatus is also available for ordinary messages by wire, and for such purposes Prof. Pupin still retains the right to it. He believes that it will greatly increase the sending capacity of telegraph wires. Taking the professor's own description of his invention, "there is an infinite number of points on the scale of inductance, and it is possible so to adjust two wires that they may receive messages from each other at this infinity of attunements." This would make it extremely difficult for a hostile operator to pick up a wireless message. It would have been interesting to hear what Mr. Marconi has to say on this subject of tuning at the Royal Institution to-night, but unfortunately he is at present laid up by an attack of influenza, and the discourse which he was announced to deliver on the progress of electric space telegraphy has been postponed to a special Friday evening on June 13. In this emergency Prof. J. A. Fleming has kindly agreed to deliver a lecture on "The Electronic Theory of Electricity" at the Royal Institution to-night.

Lightning Conductors.—A correspondent of the *Standard* in a short communication under the above title offers a number of useful hints on the subject of lightning conductors, which he commends to the attention of the Lightning Research Committee. The earth connection he regards as "the very heart of a lightning conductor," and should, therefore, receive more attention than is usually bestowed upon it. From actual experience the writer makes the following suggestions: The conductor should be of only one kind of metal from earth-plate to point; if of iron, the pieces should be welded; if of copper, very hard brazed, with protection of brazed part against decay.

Digitized by Google

Where joints are unavoidable, care is to be taken, not only that the electrical connection is sound at the time, but that without attention it will be likely to remain so. An easy means is required for testing the connection between each earth-plate and its lead above ground. In his judgment, the first object of a conductor is to establish connection between earth and sky in such a manner that there is a constant flow, restoring gradually, instead of suddenly, the balance of electrical pressure, thus anticipating and preventing, or, at any rate, greatly mitigating, the violence of a discharge For this purpose he thinks that an electrically perfect connection between one steeple conductor and a good earth connection (more than one if possible) would protect a good area all round, forming, as it would, a cloud of earth electricity, on which that of the storm would expend its force. That such a flow takes place the writer is assured by the evidence of his galvanometer when testing on the approach of a storm. The second object of the lightning conductor—but one which in the minds of the majority seems to be the first idea—is the carrying off of a strong discharge. In this case a large amount of wire entanglement is required to catch the lightning. He advocates separate systems, with loose, detachable wire connections, through which lightning will pass, as thus it is easy to test the efficiency of each system and the connection with and resistance of its earth, both important matters.

Electricity in Cotton Mills.—The advantages of electricity for driving purposes in the large cotton mills of America is the subject of an interesting article by Mr. W. B. S. Whaley, recently published by *Dixie*. It seems that in these electrically-driven mills the motors are placed overhead, so that they occupy no floor space, with the additional advantage that they are quite out of reach of the hands employed in the works. No special machinery is required for lighting the mill, as current for this purpose is taken from the generator producing the power. By actual experience with electrical driving, there is a saving in friction alone of 20 per cent. Also, the producing capacity of the machinery operated is, in actual practice, increased about 4 per cent., due to the steadiness of this method of driving over the ordinary practice of ropes and belts, and to the more uniform speed obtained throughout the plant. The economic problems solved by the installation of these electrically-driven cotton mills are, therefore, very important, and are a great advance on all previous practice. The plants are also readily available for furnishing current for power purposes outside the mill itself, and a considerable additional revenue from this source is often secured, as they can supply power at a lower figure than that at which isolated plants can generate. For example, in Columbia, S.C., the Olympia Mills power plant not only drives three different cotton mills, but also furnishes the light and power company with current for working their street cars and for lighting purposes, and more economically than the individual companies could maintain separate plants, while the Olympia Mills sell the current at a substantial profit. Another State which is making great advances in this direction is South Carolina, which will shortly have no less than 15 of these electrically-driven cotton mills in operation. Electricity is also finding extensive use in the sawmills of America. In one instance the company not only supplies power for its machine shops, etc., but also lights a large hotel and several other buildings in the neighbourhood of its works. The electrical plant installed consists of four 45-kw. and two 400-kw. 250-volt direct-current dynamos, the former being driven by a 225-h.p. Reynolds-Corliss engine and the latter by a direct-connected Harrisburg engine of 150 h.p. The combined electrical horse-power is over 300, and capable of 50 per cent. overload for long periods, or 100 per cent overload for short periods.

Fuel Oil.—In an interesting paper presented to a scientific society in Texas last month, Mr. W. W. Reed discusses the comparative advantages of oil and coal fuel for steam purposes, deciding ultimately in favour of the former, not only on account of its low cost, but because of the many other advantages to be gained by its use. In comparing the heat values of the two fuels, the author takes as his basis of comparison the number of heat units contained in each. Thus he gives as the heat value of petroleum from 17,000 to 20,000 British thermal units, and assumes an average value of 18,500 British thermal units. For the different coals found in the States he gives values ranging from 9,900 to 13,500 British thermal units, with an average value of American coal of 12,225 British thermal units. On this basis one barrel of crude petroleum weighing 320lb. net would be equivalent to 491lb. of coal. From this value, then, a calculated number of barrels of oil to equal one ton of coal would be 4·12. Of course, in actual practice the value of oil, as compared with coal, would vary, depending on many factors, such as grade of coal, efficiency of the burner or atomiser, furnace construction, etc. But results based on actual practice are from 2½ to 4 barrels of oil to a ton of soft coal. In using fuel oil, the cost of handling the fuel in a steam plant is said to be greatly reduced, and, moreover, the steaming capacity of the boilers is increased in the neighbourhood of 35 per cent. In an instance which the author quotes, that of the Houston Lighting and Power Company, with a certain load on the generators, one boiler using oil now does easily what formerly required two boilers using coal. A test was recently made by this company on two Babcock-Wilcox boilers, and an evaporation of 13·48lb. of water per pound of oil was obtained from and at 212deg. F. In another case an evaporation of 14·71lb. of water per pound of oil was got from and at 212deg. F. At the works of the Houston Company the oil is stored in steel tanks of 12,000 gallons capacity each, which are provided with heating coils to heat the oil in cold weather. The oil is pumped from the storage tanks into a small receiver, where it is heated to a high temperature by the exhaust steam from the pump. It is then forced to the burners under pressure, the pump, being automatic in its action, maintaining a constant pressure of oil, no matter how much oil is being used. While the author admits that oil, which he describes as an ideal fuel, will never entirely replace coal in steam plants, its use in Texas and many other parts of America will be very extensive in the near future.

The Electrolytic Rectifier.—Some experimental results obtained by Messrs. C. F. Burgess and C. Hambulchen, and recently explained before the American Electro-chemical Society, tend to show that the electrolytic rectifier may become an industrial apparatus, which for certain cases may successfully compete with rotary converters and motor-generators. The principle of the electrolytic rectifier is based upon the well-known property of the aluminium plate to allow a current to pass in one direction, but not in the other. Instead of aluminium, certain other materials may also be used; but at present aluminium seems to be the most promising material. The fact that an aluminium plate, when used as an anode, does not allow a current to pass is assumed to be due to a coating of aluminium oxide, which is insulating. This oxide film is, however, not a perfect insulator, as it does not prevent a small leakage current which passes through spots of the plate irregularly distributed over the surface.

Digitized by Google

The authors discussed the different losses in the cell. There is the $C^2 R$ loss, which cannot be determined as though the total surface of the plate was conducting, because the active aluminium surface is much reduced. Another loss is E C, where E is the counter E.M.F. due to decomposition. There is also the leakage current loss. The first experiments were made with electrodes of aluminium and lead in potassium phosphate, but the authors were unable to get a higher efficiency than between 30 and 40 per cent. The amount of leakage, however, was the main point to which they gave attention. They found that with continuous pressure applied the amount of leakage is very small, while it is much larger with alternating pressure applied. There is a similar difference regarding the point of breakdown due to excessive sparking. The plate breaks down at a much lower voltage with alternating pressure than with constant pressure. It is therefore not allowable to use results obtained with constant pressure for drawing conclusions regarding the behaviour under alternating current. While the experiments with solutions were not very promising for an industrial application of the electrolytic rectifier, they obtained far better results by the substitution of a fused electrolyte for the solution. They employed fused sodium nitrate and obtained an efficiency of over 80 per cent. This result makes it quite possible that the electrolytic rectifier in this form may be used in practice. It may be used, for instance, for charging storage batteries in localities where only alternating current is available, and the authors have made elaborate tests concerning the question whether a pulsating current, such as obtained from a rectifier, has any advantages over a steady direct current for charging a battery. They, however, could not detect any difference between the two types of current for the resulting efficiency and capacity of the battery. We understand from our contemporary, the *Western Electrician*, that a continuous test of the rectifier, lasting over a considerable period, has also been made in order to determine the cost, which comes out at about one-eighth penny per kilowatt hour. This result makes the apparatus appear promising for industrial application.

Magnetic Shielding.—The current number of the *Proceedings* of the Royal Society of Edinburgh gives a very concise abstract of a paper read before the society last March on the subject of magnetic shielding in hollow iron cylinders, by Mr. James Russell. The author's investigation deals with the shielding which exists within hollow iron cylinders when placed in a uniform transverse magnetic field. This transverse field divided by the internal magnetic field is defined as the shielding ratio. For the thin iron cylinders experimented with, it appears from various mathematical contributions to the subject that the shielding ratio minus unity may for present purposes be taken to be proportional to certain geometrical data and to the permeability (the permeability being large). By means of a rotating inductor within the shield, connected with a ballistic galvanometer, experimental determinations of the shielding ratio are made under various conditions of magnetisation; and an endeavour is also made to show how far and under what conditions these results approximate to theoretical formulæ which assume the permeability to be uniform all round the shield, and the absence of retentivity and coercive force in the iron. Two iron shields were experimented with, the hysteretic constants (η) being ·0015 and ·0028 respectively. The following results have been arrived at—viz.: First, that when no other magnetising force is acting upon the iron than that due to the transverse field increased by increments from zero, the shielding ratio minus unity is proportional to what may be called the ratio permeability (B/H), and not to the differential permeability (d B/d H). If, however, the transverse field is decreased by steps from a maximum, the theoretical conditions are not fulfilled, and the shielding ratio increases very rapidly and becomes infinite, but does not change sign if account be taken of the negative residual field within the shield when at each step the transverse field is withdrawn. In the second place, when a circular magnetising force is acting upon the iron in addition to that due to the transverse field, the order and manner in which the one field is superposed upon the other affects the shielding ratio to an enormous extent. The conclusions arrived at are not in harmony with the inductions drawn from the investigations of Stefan and Du Bois which "lend support to the assumption made throughout that shielding against moderate disturbing fields depends within due limits upon the constant permeability for small increments or decrements of force superimposed upon any condition of magnetisation." It is found that when, upon a pre-existing induction due to the transverse field, increments of the circular field are superposed (T C conditions), the shielding ratio minus unity is proportional to the differential permeability as impressed upon the iron by the circular field. The shielding ratios plotted as ordinates against the corresponding values of the circular field as abscissæ rapidly increase, attain a maximum, and then decrease, finally approximating to a minimum asymptotic value. If, however, upon a pre-existing induction, due to the circular field increasing from zero, the transverse field is superposed at each increment (C T conditions), the shielding ratio curves take much lower values. The superposition of repeated reversals of the transverse field (C T T conditions) still further lowers the shielding ratio, and in this case there appears to be no initial rise as the curve leaves its origin in the vertical axis. On the other hand, the superposition of repeated reversals of the circular field (T C C conditions) increases the shielding ratio so long as the values of (d B/d H) are high. When the values of d B/d H are a maximum, the shielding ratio under the T C C conditions are six to seven times greater than under the C T T conditions. The curves obtained under all the conditions of superposition of fields appear to approximate to the same minimum value as the circular magnetising force is further and further increased. A distinction is drawn between the permeability of the iron to the circular field and the permeability of the iron to the transverse field. Thus, while under the T C conditions the shielding ratio minus unity is proportional to the permeability (d B/d H) of the iron to the circular force, the same does not hold good under, say, the C T conditions. The effect of repeated reversals of the transverse field is shown to increase the permeability of the iron to the force which remains constant—viz., the circular field—and, in virtue of the phenomena associated with hysteresis, to lower the permeability of the iron to the transverse field, and consequently also to lower the shielding ratio. Further, when, upon a pre-existing induction due to the transverse field, the superposed circular field carries the iron round a complete cycle, the shielding ratio curves resemble the theoretical curves obtained from the corresponding values of d B/d H impressed upon the iron by the circular field. The effects of a longitudinal magnetising force acting upon the iron in addition to that due to the transverse field have not yet been fully investigated. Preliminary experiments show that in this case also the order and manner of field superposition largely determine the shielding ratios; also that when, upon a pre-existing induction due to the transverse field, increments of the longitudinal field are superposed, the differential permeability appears to be the determining factor.

OLDHAM CORPORATION ELECTRICAL TRAMWAYS.

These tramways were formally opened last week, as a number of lines were ready for electrical working. The history of the undertaking shows that the tramways in Oldham were originally constructed by the Corporation under parliamentary powers. The first section running throughout the town was laid in 1880, and was constructed

COUNCILLOR J. ECKERSLEY, J.P., MAYOR OF OLDHAM.

for horse traffic. An extension of the tramways was made in 1884, the track being laid north and south across the borough, and this section was designed for steam traffic. The above sections were leased separately on completion to two different companies at rentals based on certain percentages on the outlay: the first to the Manchester Carriage and Tramways Company, and the second to the Bury, Rochdale, and Oldham Steam Tramway Company, the leases to the two companies being arranged so as to terminate at the same time—viz, Oct. 31, 1901—when

COUNCILLOR J. A. HANSON, VICE-CHAIRMAN OF THE OLDHAM TRAMWAYS COMMITTEE.

power to use and work the same reverted to the Corporation. For a considerable time prior to the expiration of the leases of the old tramways, reconstruction suitable for electric traction had been discussed, together with an extension of the tramway system throughout the borough, and in 1899 parliamentary powers were obtained to construct about 12¼ miles of single-track electric tramways, covering about 10 miles of route, and a car depôt to accommodate 70 cars. The new tramways were commenced in Middleton-road on Feb. 6, 1900, and within two months work on three other routes was commenced—viz., Park-road and Glodwick-road, Hollins-road and Copster-hill-road, and Egerton-street. These tramways were completed as quickly as possible, and with the exception of the Egerton-street route were opened for traffic, temporary car depôts being built adjacent to each route. In February, 1901, it was decided not to proceed with the remaining tramways under the 1899 order until the expiration of the two companies' leases of the old tramway, and so the summer of 1901 was taken up in the erection of the

ALDERMAN H. CHADWICK, CHAIRMAN OF THE OLDHAM SURVEYORS' AND TRAMWAYS COMMITTEE.

car depôt at Wallshaw, which is now complete and capable of accommodating 70 cars.

On Nov. 1, 1901, the day after the Manchester Carriage Company and the Bury, Rochdale, and Oldham Tramway Company ceased to run on the old main routes, about 900 men commenced the work of reconstruction in about seven different places. The winter proved a very unfavourable one, and many weeks were lost owing to severe weather, but whenever it was possible steady progress was made until the end of April last, when the whole of the track

MR. S. A. PICKERING, BOROUGH SURVEYOR.

on the main routes was completed, with the exception of Rochdale-road, which at the present time remains unaltered, and, by agreement with the Bury, Rochdale, and Oldham Tramway Company, is still being used as steam tramways on weekly rental Featherstall-road, which is part of the old tramways constructed in 1884, but which may scarcely be called a main route, is now to be reconstructed, and also Rippondenroad, which is a new route under the 1899 order. About 11¼ miles (route) of electric tramways are now in operation, two miles nearly complete, leaving approximately eight

Digitized by Google

miles to construct. The following is a brief summary of the estimate presented at the Board of Trade enquiry :

New routes, including land for car depôt	£91,891
Reconstruction of old routes	91,778
Electrical equipment	37,901
Car depôt at Mumps	27,102
Cars	121,500

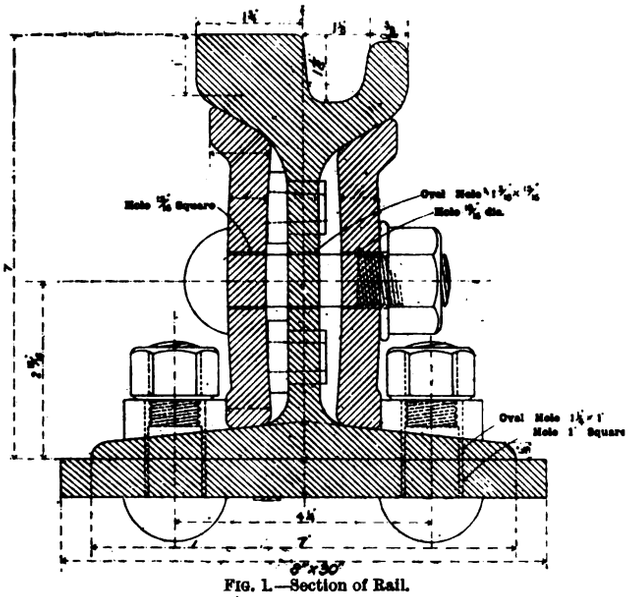

FIG. 1.—Section of Rail.

Supplementary estimate (to be presented to the Board of Trade).

Reconstruction of old routes	17,316
Electrical equipment	11,520
Car depôt at Neville-street	28,026
	£427,034

porary), erection of standards, and overhead equipment and cables, has been designed and carried out by Mr. S. A. Pickering, A.M.I.C.E., borough engineer, with Mr. H. Clegg, A.M.I.C.E., as his assistant. Messrs. Hewitt and Rhodes, of Manchester, have acted as consulting electrical engineers for the overhead equipment.

The whole of the track was constructed by Corporation workmen. The contractors for all other work are as follows: electrical overhead equipment and cables—Messrs. W. T. Glover and Co., Limited, Manchester rails, fishplates, etc.—Messrs. the Barrow Hematite Steel Company, Limited, and Messrs. Dick, Kerr, and Co.,

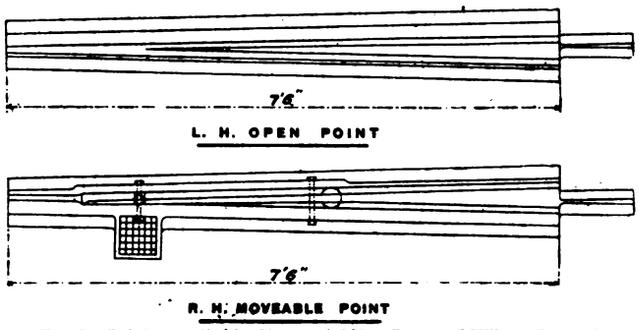

FIG. 2.—Points supplied by Messrs. Askham Bros. and Wilson, Limited, to the Oldham Tramways.

Limited, London; points and crossings—Messrs. Askham Bros. and Wilson, Limited, Sheffield; cars—Messrs. the Electric Railway and Tramway Carriage Company, Limited, Preston; car depôt—Mr. Edward Stephenson, Oldham; car depôt (steelwork)—Mr. Jno. Mundy, Glasgow.

The rails used on all new work and in relaying old tracks are rolled to a special section (Fig. 1), and are 100lb. per yard in weight. The contract for the supply of these has been in the hands of two firms: the first contract was given to the Barrow Hematite Steel Company,

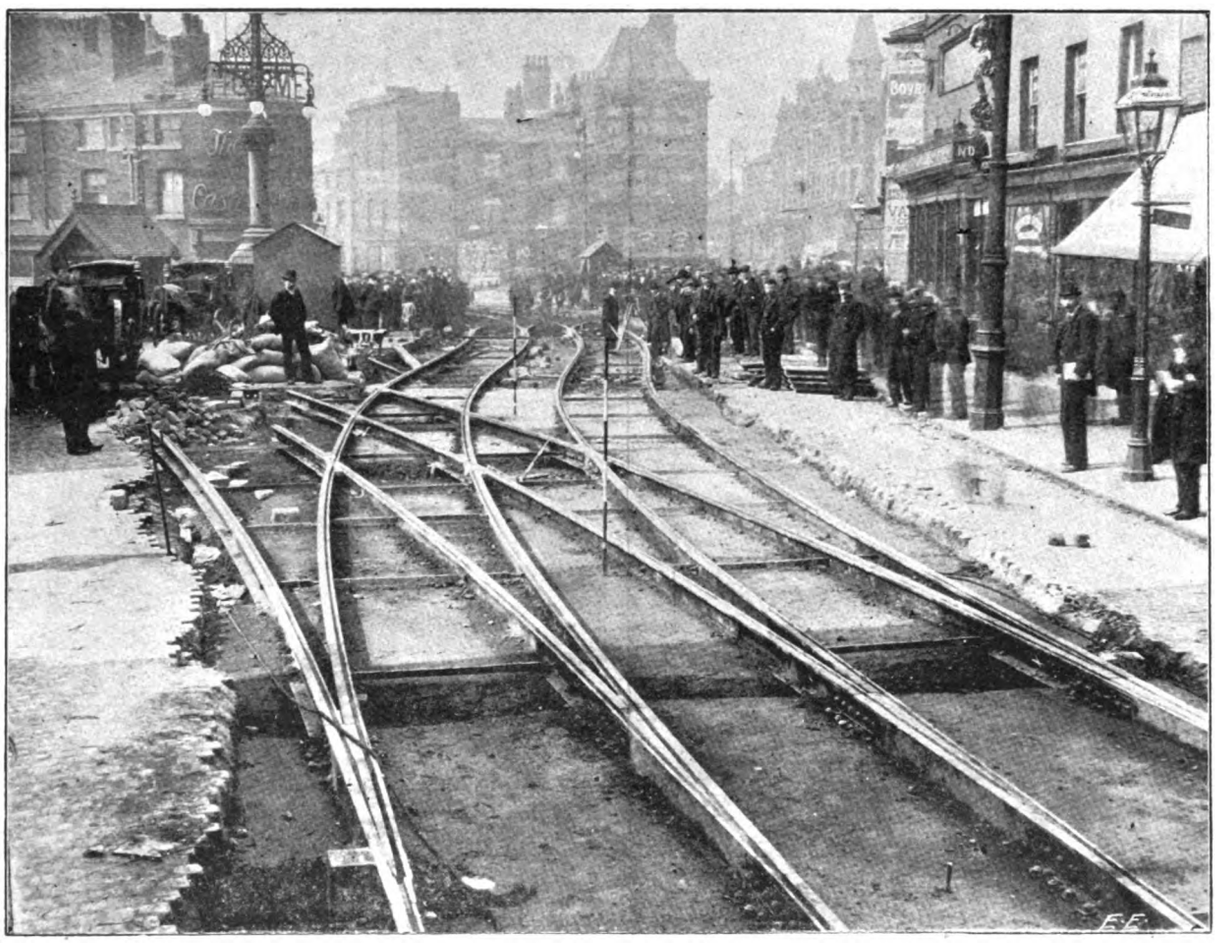

FIG. 3.—Special Work at Oldham, supplied by Messrs. Askham Bros. and Wilson.

The whole of the undertaking, including the construction of the track, building of depôts (permanent and tem-

Limited, and they supplied about 2,000 tons, terminating their contract about March, 1901; the second contract,

for 3,000 tons, was given to Messrs. Dick, Kerr, and Co., Limited, who have now supplied about 2,000 tons. The two sections of rails differ slightly, the width of the head of the Barrow rail being ½in. less than that supplied by Messrs. Dick, Kerr, and Co. The jointing of the two makes are also different. With the Barrow rail separate sole-plates and fishplates are used, whilst with Messrs. Dick, Kerr, and Co.'s rail the fishplates and sole-plates are rolled in one piece. Fourteen bolts are required to complete the former joint, six for the fishplate and eight for the sole-plate; six bolts only are required for the latter joint, the sole-plate being constructed so as to grip the lower flange of the rail. The weight of the Barrow fishplate is 44lb., as is also the weight of the sole-plate. The weight of Messrs. Dick, Kerr, and Co.'s fishplate and sole-plate is 123lb. Tie-rods have been supplied by Messrs. Askham Bros. and Wilson, Limited. They weigh 16lb. each, and are 5ft. long by 2in. by $\frac{7}{16}$in. They are fixed every 9ft. in the track, and are secured by four bolts, two on each side of the web of the rail. There are 32 double junctions in the system, besides numerous passing-places, turn-outs, and the special work at the Wallshaw car depôt. All points (Fig. 2) and crossings, excepting those at the depôt, have been supplied by Messrs. Askham Bros. and Wilson, Limited. Approximately 183 pairs of points and 279 crossings have been used in the track laid down up to date. Figs. 3 and 5 give some idea of the character of this work as put in at

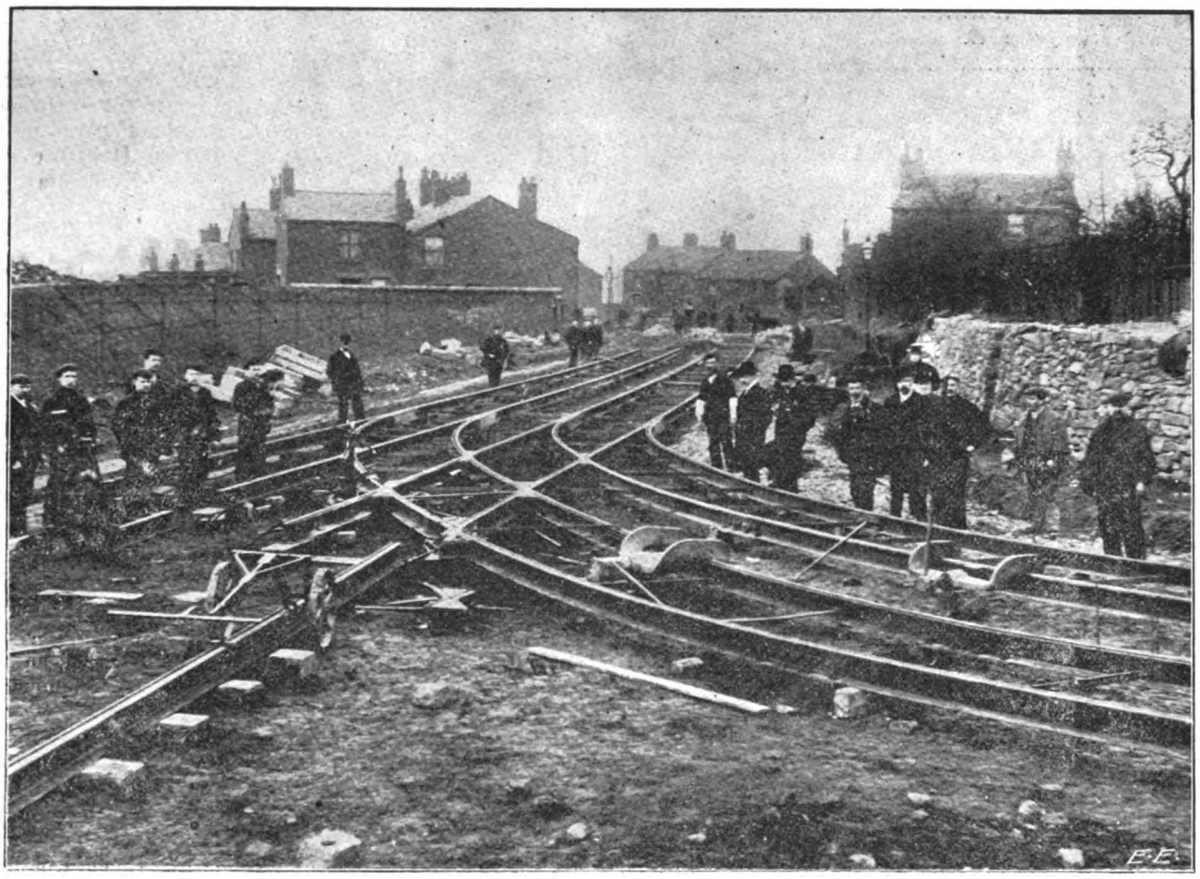

FIG. 4.

FIG. 5.

Digitized by Google

the principal crossings of the routes. The bonding of the rail joints is effected by means of stranded copper bonds, two to each joint, each 6¾in. long, and equal in area to 166 square inches. At points and crossings solid bonds of varying lengths are used. These are 4/0 gauge, and of the same sectional area as the stranded bond. Solid cross bonds have been laid every other rail, or at intervals of about 30 yards. Messrs. Glover and Co., of Salford, have been the contractors for the bonds, and up to the present date have supplied about 12,000.

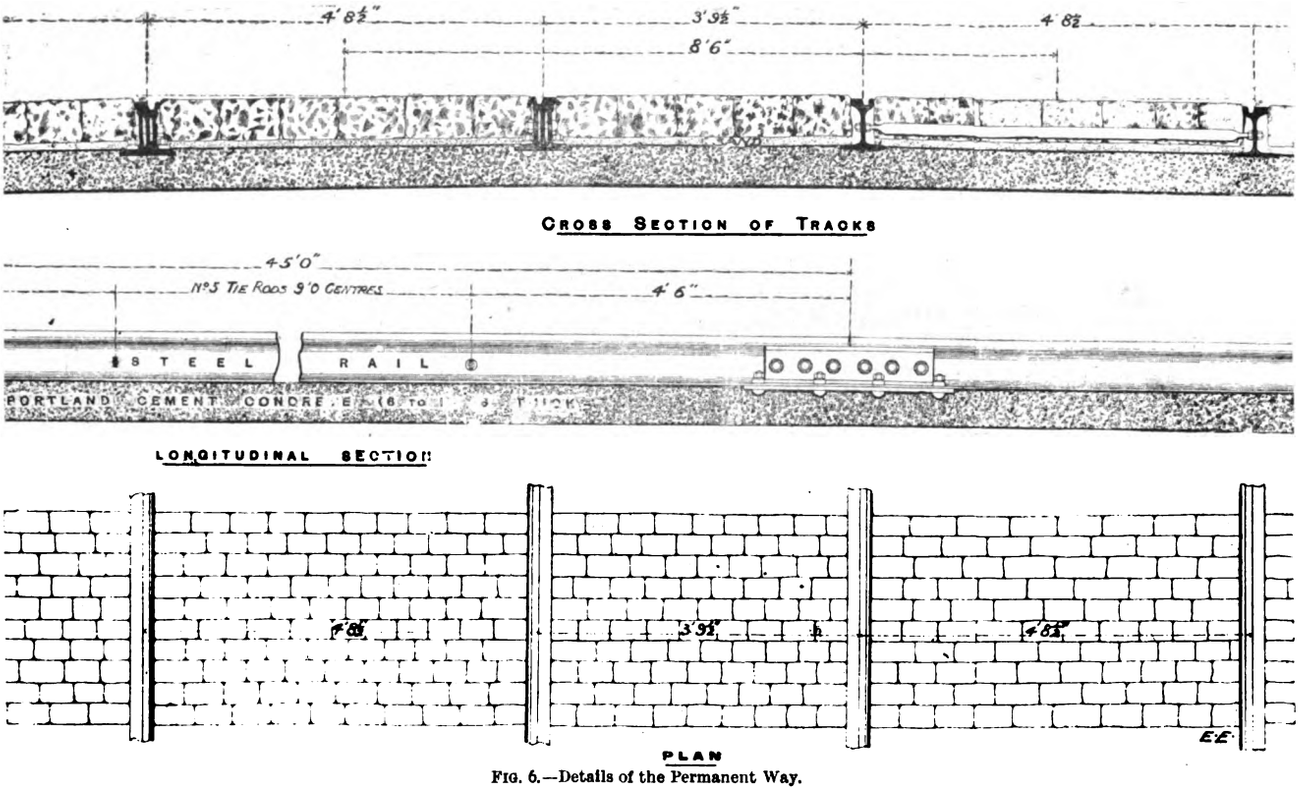

FIG. 6.—Details of the Permanent Way.

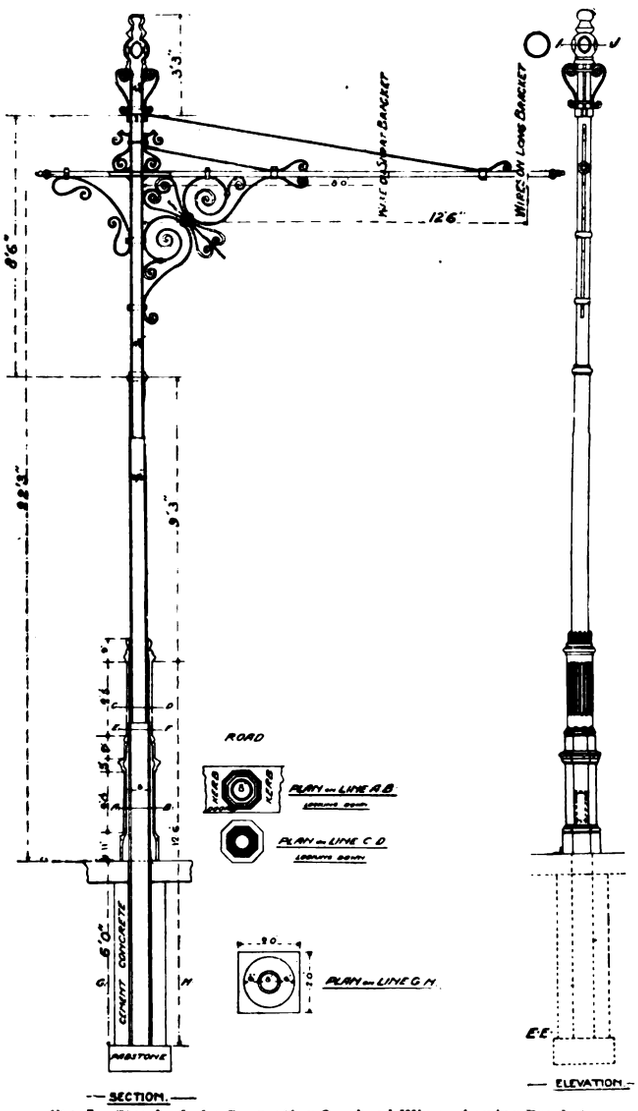

FIG. 7.—Standards for Supporting Overhead Wires, showing Brackets, supplied by Messrs. J. Spencer, Limited.

The following particulars of the track work as carried out by the Corporation workmen will be of interest. The existing carriageway with its foundation—if it be unsuitable—is first taken up and the ground further excavated and prepared to a depth of 13in. below the proposed finished level. In places where, by reason of the removal of unsuitable foundations, a greater depth than 13in. below the proposed finished level has been attained, a bed of ballast, well rammed, is laid to form the proper level. The rails are then laid upon old setts placed at intervals of about 15ft., and with the necessary small packings between sett and rail the proper gradient of the permanent way is arrived at. The rails are laid to a gauge of 4ft. 8½in., and tied in with tie-rods at 9ft. centres. On every curve of whatever radius the outside rail is given the necessary amount of elevation above the inside rail, the calculation being based upon a speed of eight miles per hour. Double tramway tracks (Fig. 6) on the straight are laid at 8ft. 6in. centres, but where they happen to be on the curve a greater centre than 8ft. 6in. is necessary to prevent two cars coming into contact whilst passing each other. When the rails are satisfactorily laid, concrete foundations, of 6 to 1 concrete, are laid to a depth of 6in. Great care is always taken that the concrete is made thoroughly solid and tight between the ground and the bottom flange of the rail; the width of the track concreted is 8ft. for single track and 13ft. 6in. for double track, which leaves 1ft. 6in. on each side of the rails. To complete the formation of the carriageway, 6in. local or granite setts, according to the locality and gradient of the road, are paved on a bed of sand 1½in. thick, the setts being laid about ½in. higher than the tread of the rail, and properly toothed into the existing carriageway between the kerb and the rail. The level of the road and its suitability for a permanent way is always duly considered, and when it is found that an improvement may be made, the full width of the carriageway is taken up. In such cases the carriageway between the kerb and the track limit is provided with a good foundation of rubble and ballast, at least 6in. thick, together with a bedding of sand 1½in. thick. The old setts are used again where possible.

The worst gradient in the whole system of tramways

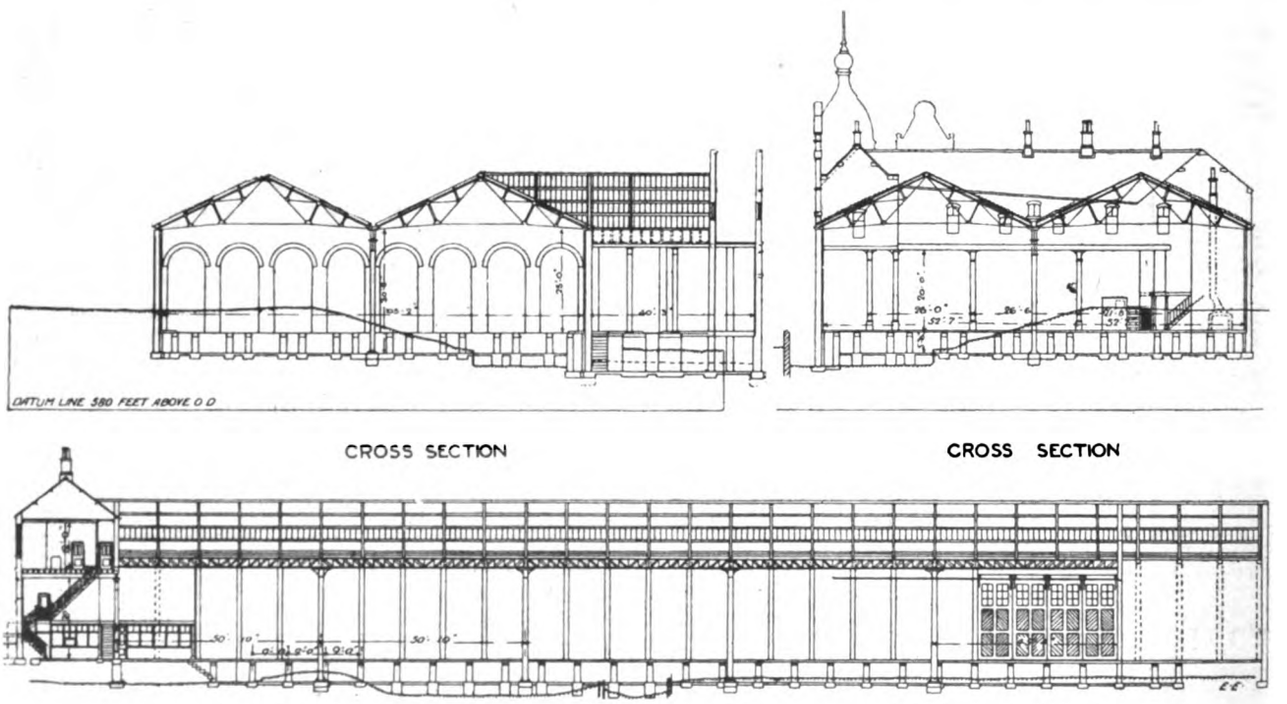
ELEVATION TO WALLSHAW PLACE

FIG. 8.—Elevations of the Mumps Car Sheds, Oldham.



LONGITUDINAL SECTION

FIG. 9.—Sections of the Mumps Car Shed.

The standards for the overhead work (Fig. 7) were made by Messrs. J. Spencer, Limited, of Wednesbury. The steel used for the poles is the best weldable steel. Each pole consists of three telescoping lengths, with the joints thoroughly rolled and welded solidly. The butt end of the pole is 12ft. 6in. long, the intermediate length 9ft. 3in. long, and the top end or length 8ft. 6in. long.

Digitized by Google

There are three types of poles—viz.: (1) a bracket pole; (2) a span-wire pole; and (3) a terminal pole. The first type (bracket pole) is 8in. diameter at the base, tapering to 4⅞in. at the top, with a uniform thickness of metal throughout of ⅜in. The second type (span-wire pole) is 7in. at the base, tapering to 4½in. at the top, with a uniform thickness of metal throughout of ¼in. The third type, or terminal pole, is 10in. diameter at the base, tapering to 6¼in. at the top, the metal throughout being of a uniform thickness of ½in. The poles, without base or scrollwork, are subjected to varying tests, as set forth in the specification. The bases are of cast iron, made in two sections, having ornamental mouldings and coat-of-arms cast thereon in high relief. Each bracket pole (Fig. 7) is fitted with ornamental scrollwork in wrought iron, and fitted so as to act as a support to the bracket arm. At the junction of each section of a pole cast-iron moulds are fixed, which hide the jointing.

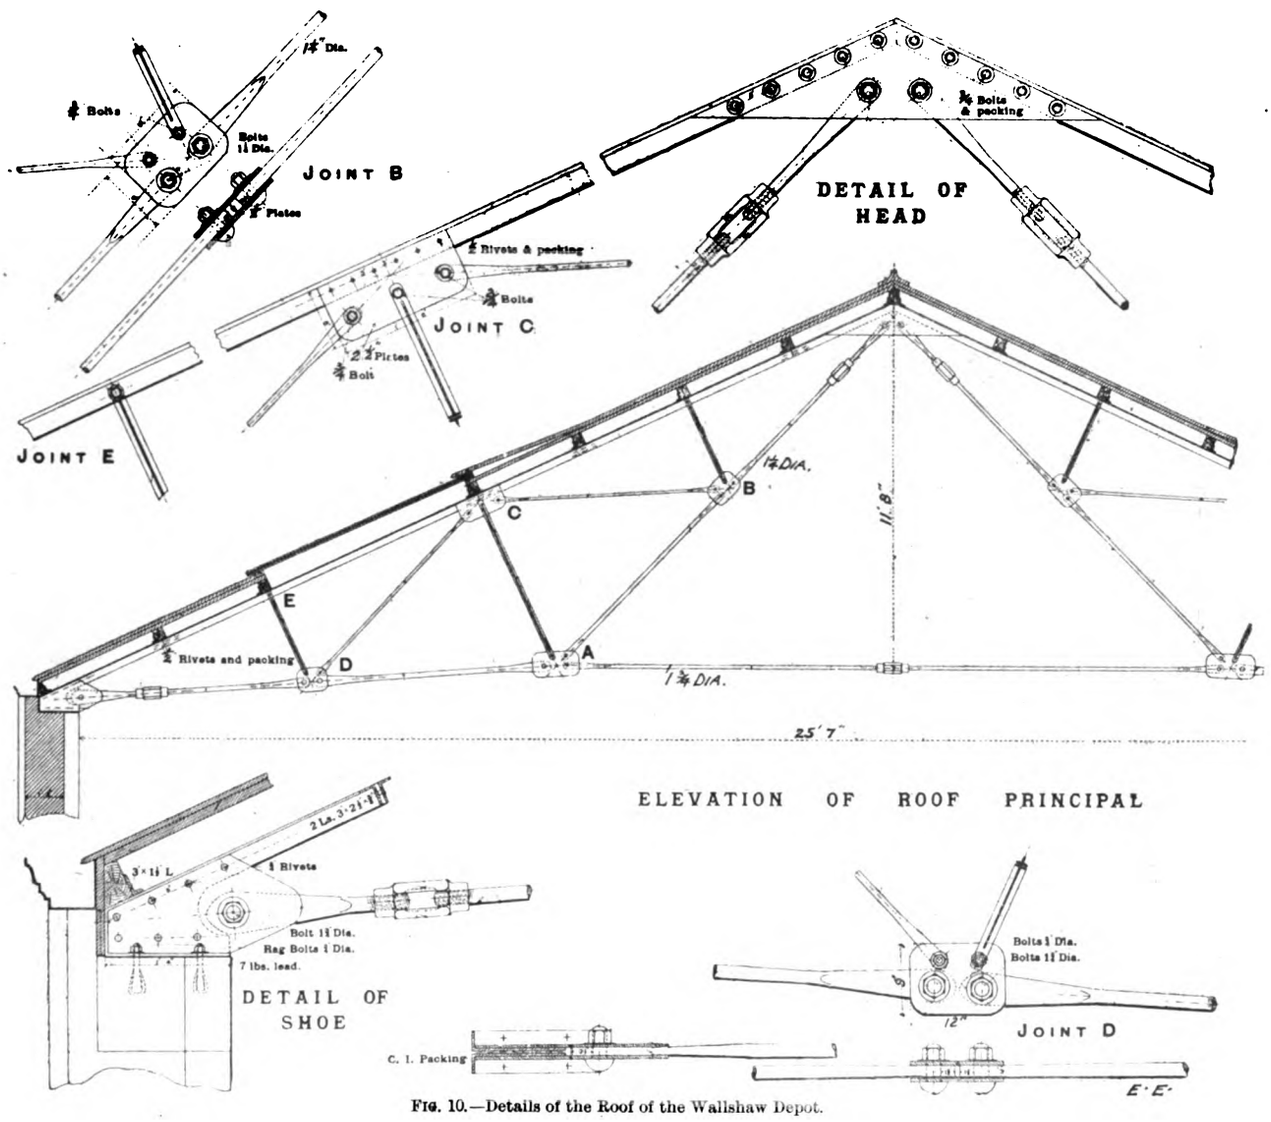


FIG. 10.—Details of the Roof of the Wallshaw Depot.

The electrical equipment has been supplied by Messrs. W. T. Glover and Co., Limited. To convey the current one large feeder cable is taken out from the generating station to each route and gradually diminished in size. There are five feeder cables, varying from ·75 square inch to ·1 square inch in sectional area. All cables are drawn into earthenware conduits through drawing-in boxes placed at intervals along the route. The cables are of Messrs. W. T. Glover and Co., Limited, own make, and the insulation is impregnated paper, lead-covered. There are 25 feeding points on the route, and the number of section

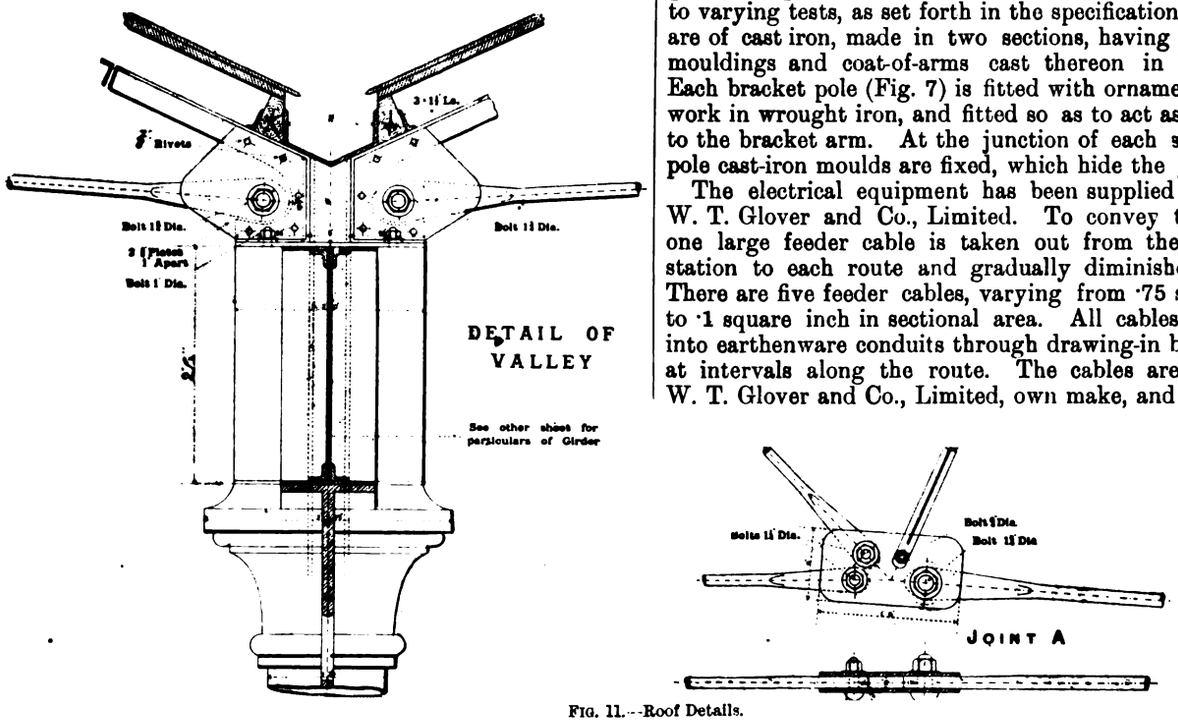

FIG. 11.—Roof Details.

Digitized by Google

boxes is 45. The telephone system is not yet installed, but it is proposed to fix a telephone in each section pillar communicating to the car-shed. The overhead trolley wire is 3/0 gauge, and two wires are used throughout the system.

Messrs. Smith and Sons, Anaconda Works, Salford. The overhead fittings were mostly supplied by Messrs. Estler Bros. Guard wires of No. 8 steel are fixed where necessary, in accordance with the Post Office and Board of Trade regulations.

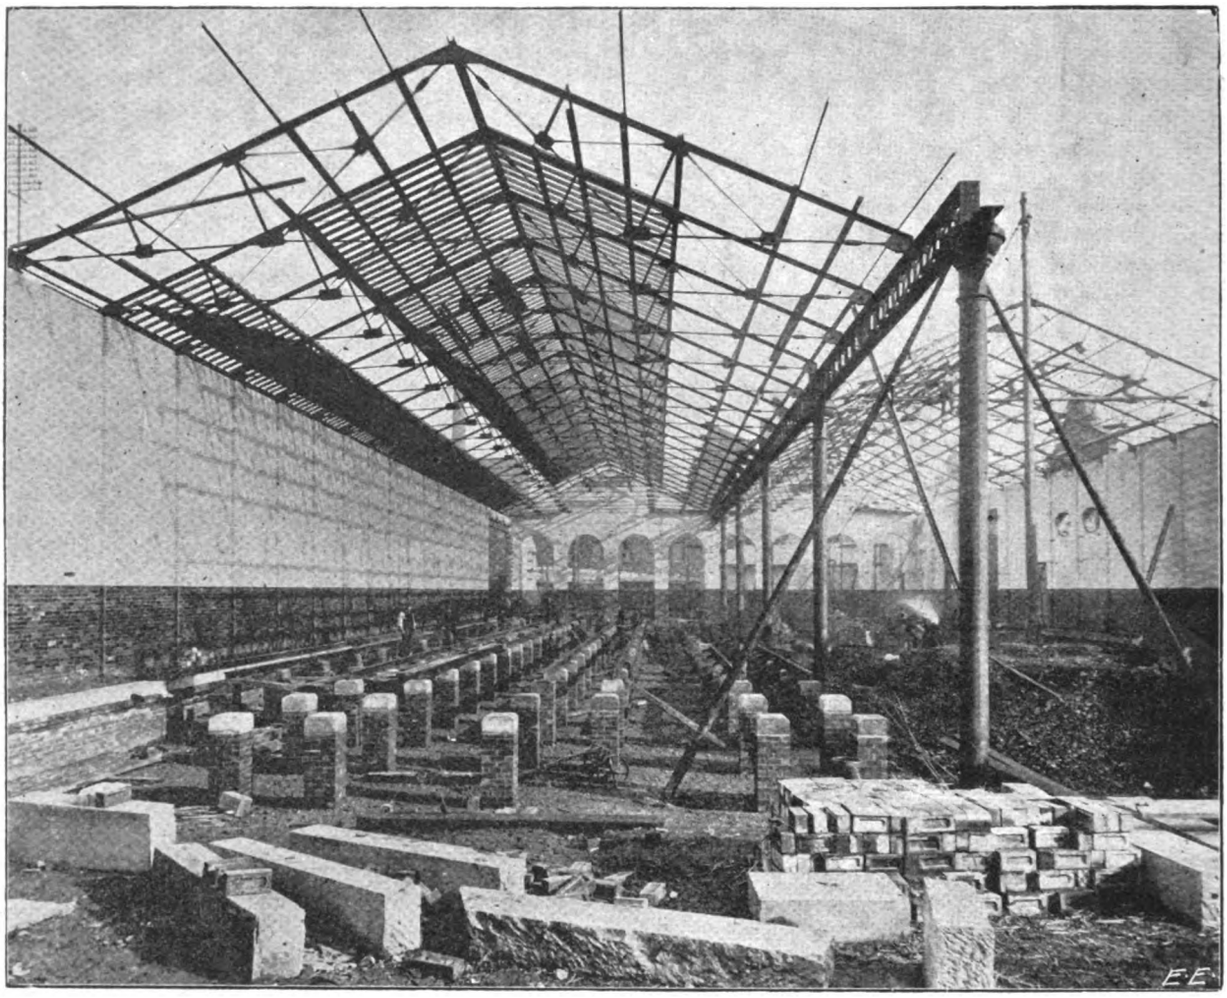

FIG. 12.—Car Shed in course of Erection.

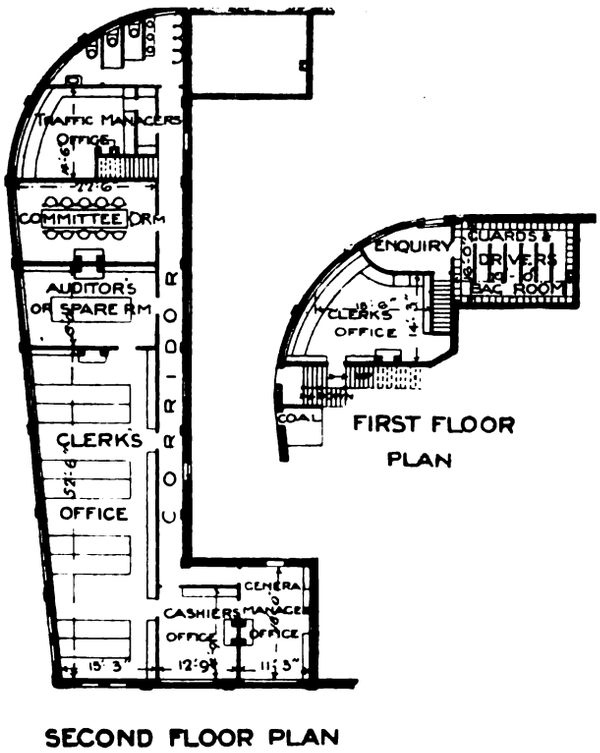

The car depôt at Wallshaw Mumps (Figs. 8 and 9) was originally constructed to accommodate 70 cars. It is approximately 111 yards long by 35 yards broad and 25ft. high from the rail level to the underside of the roof principal (Fig. 10). There are eight tracks into the depôt, converging from one single track at the entrance, necessitating an amount of special work with 44 points and 22 crossings. The car-pit for the examination of car trucks is constructed over the whole width and length of the car-shed, the rails being fixed to brick piers 1ft. 6in. square and 5ft. 6in. high, built at 9ft. centres. Six turntables of varying diameter are constructed at the east end of the building for use in turning the cars out into the new street behind the shed, from whence they may be run into Wallshaw-street and out on to the main line in Yorkshire-street. There are four workshops at the extreme end of the building, which are to be fitted with suitable machinery, such as motors, lathes, circular saws, milling machine, blacksmiths' hearths, etc. The

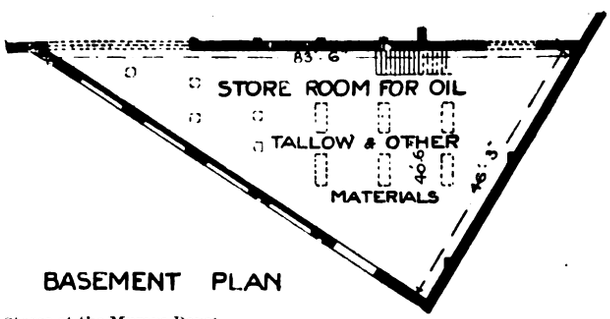

FIG 14.—Details of Offices and Stores at the Mumps Depot.

They are fixed 22ft. 3in. above the level of the carriage way. The material is hard-drawn copper wire with conductivity of 99 per cent. The manufacturers of this were

main shed is divided into two bays, the roof principals being supported in the middle by a lattice girder 2ft. 6in. deep, and supported on five cast-iron columns 28ft. long (Fig. 13). The offices (Fig. 14) are situated at the west end of the building, and comprise a manager's office, cashier's office, clerks' office, auditors' room and committee room, traffic manager's office, guards' and drivers' room, bag room, enquiry office, lavatories, etc. The construction of the building involved the following materials: 2,000 cubic yards of excavation; 1,200 cubic yards of concrete; 8,257 square yards brickwork, reduced to 9in. work; 200 tons of steelwork in roof principals, etc; and 100 tons of girder rails.

The cars used on the lines were manufactured by the Electric Railway and Tramway Carriage Company, Limited, of Preston. Three different types of car are in use—*i.e.*, a single-deck single-truck car, a single-back bogie, and a double-deck car with a single truck. The seating capacities of these cars are respectively 28, 36, and 58. The trucks are of the Brill type, and the electrical equipments were manufactured by the English Electrical Manufacturing Company, also of Preston. All the motors are of 25 h.p., and the number of motors per car varies from two to four, according to the type and weight of the car. The controllers are of the same firm's make, having the solenoid blow-out. The trolley heads are of the Wilkinson type, and Messrs. Estler Bros. provided the trolley stand. The cars are fitted with three different brakes—*i.e.*, a handwheel brake, an electrical emergency brake, and a pneumatic slipper brake. In the front of the car Tidswell's lifeguards are fixed.

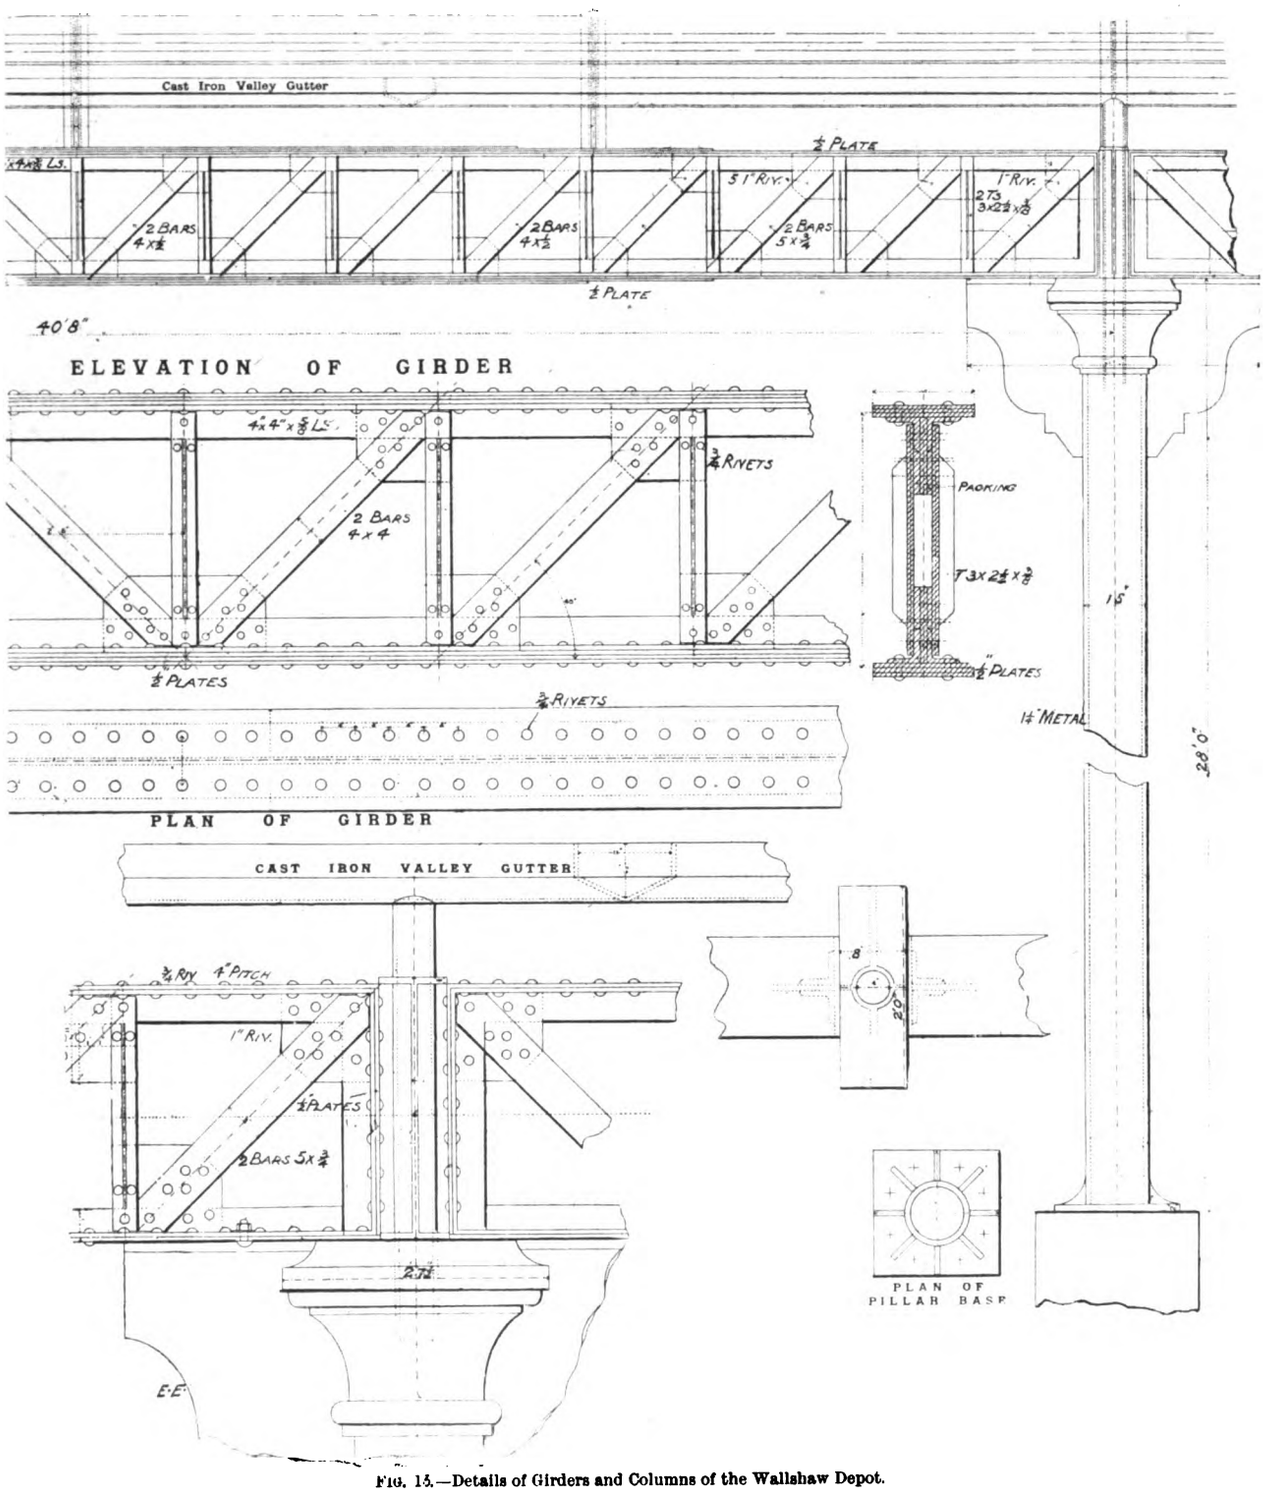

FIG. 15.—Details of Girders and Columns of the Wallshaw Depot.

The tramways service in Oldham commences at 5 a.m. in the morning and is carried on until 11.20 at night. The average frequency at present is 10 minutes, and we understand that this is to be materially reduced as soon as more rolling-stock and more power is available. The average car mileage per day is about 1,200 at present, and it is found that about 0·9 of a Board of Trade unit is the average consumption of energy per car mile. At the present time the power for working these trams is taken from the old electric lighting works, which are equipped

Digitized by Google

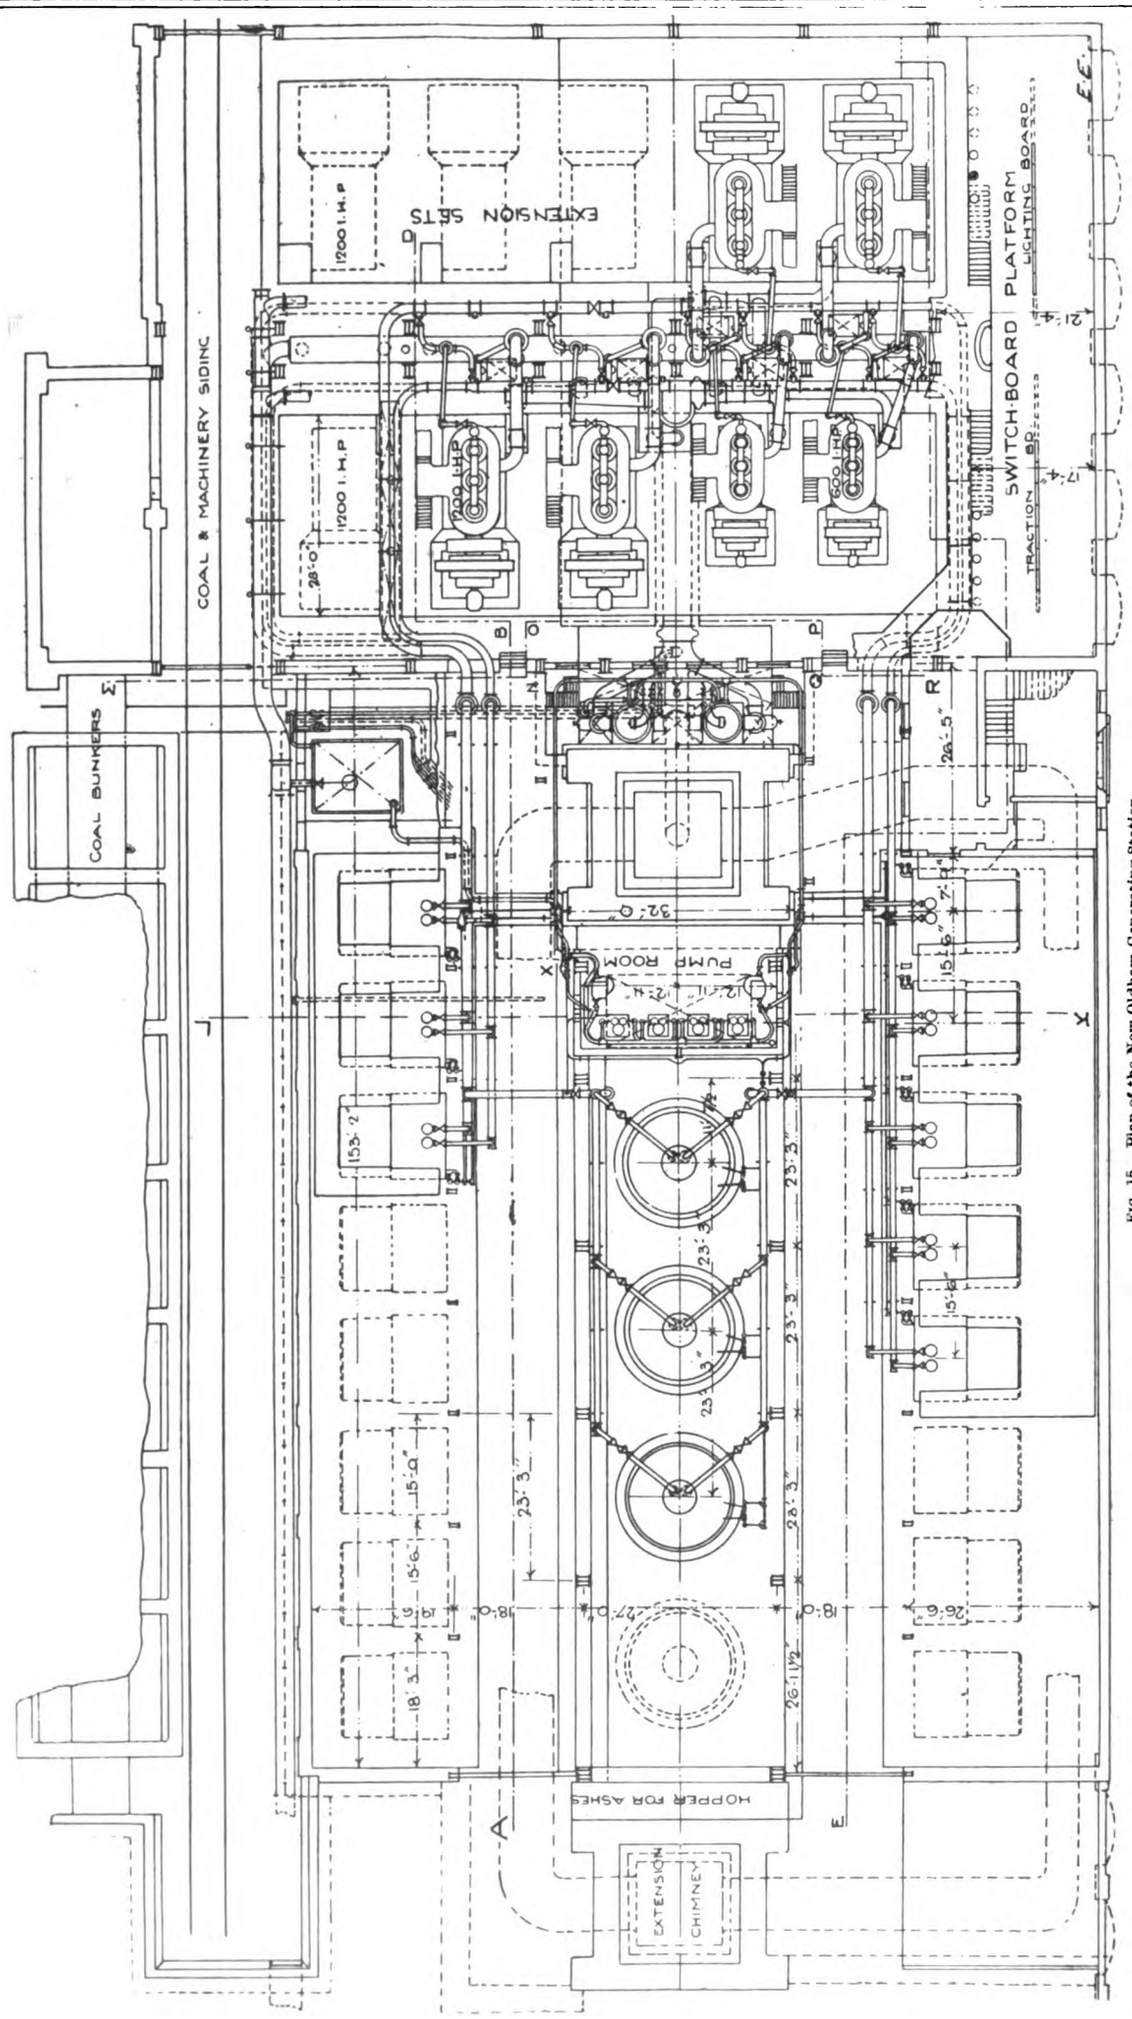

Fig. 15.—Plan of the New Oldham Generating Station.

with direct-current plant available either for traction or lighting. It was recognised, however, that this station, which is already crowded, could not contain the additional new plant required when all the tramways are at work.

Digitized by Google

On the advice, therefore, of their consulting engineer, Dr. A. B. W. Kennedy, large new generating works are being erected, but these were not in a sufficiently advanced state to be opened last week. We understand, however, that the building work is progressing favourably, and that the erection of the boilers has been commenced.

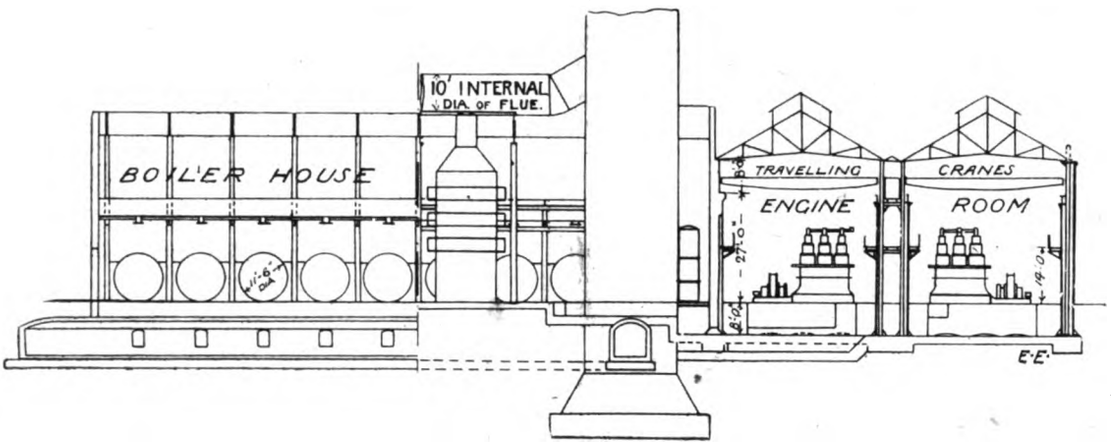

FIG. 16.—Sectional Elevation of the same.

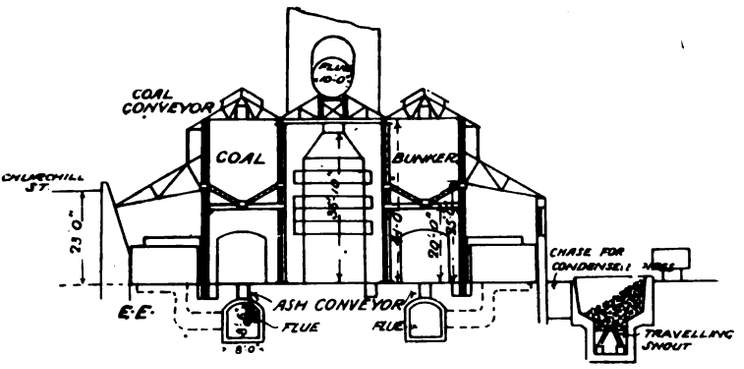

FIG. 17.—Section showing Coaling Arrangement.

Through the kindness of the consulting engineer, we are able to give the following illustration of these large works, which are novel in many respects. From the general plan (Fig. 15) it will be seen that in the boiler-house there are three lines of boilers. The outside lines consist of dry-back marine boilers, but the centre line consists of three Climax boilers, which have not been up to the present used to any great extent in this country. The flues from these boilers has from their construction to be overhead, and the details of the same can be seen in Figs. 16 and 17.

A 10ft. diameter steel flue is carried along the top of the centre bay of the boiler-room, and then into the shaft. The cross-section (Fig. 17) shows well what the coaling arrangements are for feeding both the marine and Climax boilers. The elevation (Fig. 18) gives a good idea of the feed-pipe arrangements. The contractors for the equipment of this new station are the following: marine boilers, Edwin Danks and Co., Oldbury; Climax boilers, B. R. Rowland and Co., Reddish; electric generators, Messrs. Siemens Bros., Woolwich; engines, Messrs. Willans and Robinson, Rugby; pipework, Messrs. Babcock and Wilcox, London; crane, J. Broadbent, Limited. The barometric condensers are to be of the Bulkley type, and are, we believe, the first of the kind to be erected in the kingdom. The switchboard contract has not yet been settled. We hope to give a detailed description of these large and interesting works after they are more nearly completed. The photographs which we have reproduced were taken by Mr. Percy Guttenberg, of Manchester.

At the opening ceremony on the 19th Mrs. Chadwick, wife of Alderman Chadwick chairman of the Tramways Committee, and Mrs. Hanson, wife of Councillor J. A. Hanson, vice-chairman, started the first and second cars respectively. After the procession of decorated cars had gone over the principal lines the guests adjourned to the town hall for luncheon and speech-making.

THE ELECTRIC LIGHTING OF ST. PAUL'S CATHEDRAL.

On Wednesday last we had the opportunity of inspecting the electric lighting of St. Paul's Cathedral under the guidance of Mr. C. J. Scott, who has had charge of the work for the contractors, Messrs. W. A. S. Benson and Co., Limited, of 82 and 83, New Bond-street. We purposely made our visit independent of the Press view of the lighting at 9 p.m. in order to get from Mr. Scott technical information as to the way in which the work had been carried out and the difficulties encountered. The consulting architect to the cathedral, Mr. Somers Clarke, F.S.A., has superintended the work, and Dr. A. B. W. Kennedy has acted as consulting engineer. It will give a good idea of the difficulties involved in wiring the cathedral when we state that the work has been in progress for three years. In that time between 1,100 and 1,200 lights have been wired for and erected at a cost of almost £10,000.

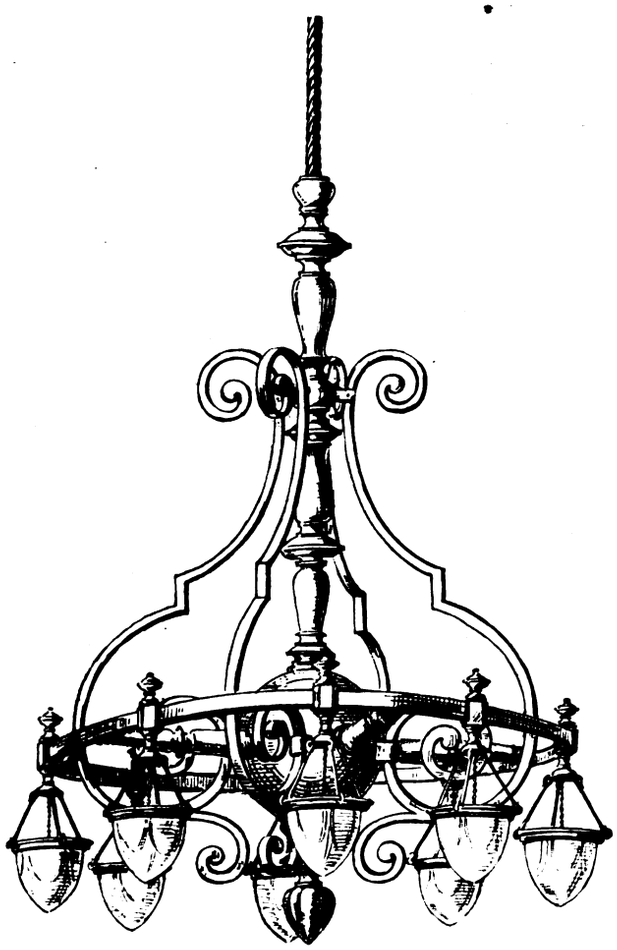

Fig. 1.—Coinage Metal Fittings for the Dome Lighting in St. Paul's Cathedral.

The supply is taken at 200 volts, half from the mains of the City of London Electric Lighting Company, and half from those of the Charing Cross and City Electric Supply Company. In this way a duplicate supply is obtained which prevents a total extinction of light if either company had a breakdown. The two circuits are, of course, kept quite distinct throughout, and alternate lights or groups of lights are connected to each, so that no part of the cathedral would be in total darkness if either supply were to fail. The arrangement of the circuits is briefly as follows: From the main boards, which are fixed near the supply terminals, a number of main circuits are run to distribution boards throughout the building. Each of these main circuits is provided at the main board with double-pole switches and fuses. A large number of these distributing boards, to which the individual circuits are connected up, are grouped together at one point in the crypt, so that the lighting of the chancel, dome, and nave can be conveniently controlled from one point. In each of the smaller circuits supplying the individual electroliers a switch and fuse is provided in each conductor. The wires are all laid in iron barrel, which, so far as we inspected the crypt, is mostly out of sight. The bulk of the mains are carried under the crypt floor, access being obtained to them by means of inspection boxes, having covers filled in with red tile to match the rest of the flooring. The rule was made

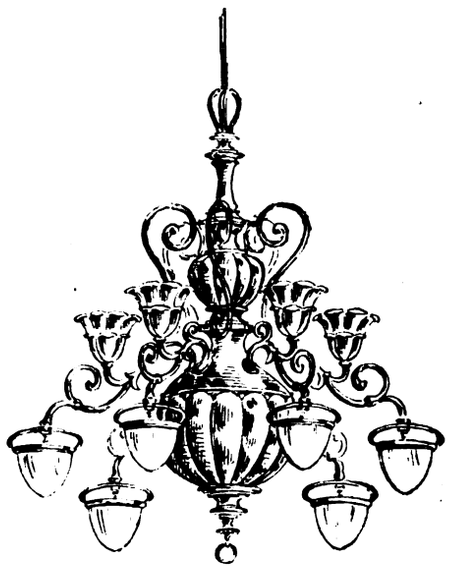

Fig. 2.—Gilded Fittings for the Chancel Lighting

that no tube was to be carried across any tomb, or across any space which might hereafter be required for interment. In consequence, the tubes have as a rule to be carried close to the walls and to follow the contour of the same, which has necessitated a large number of inspection boxes to

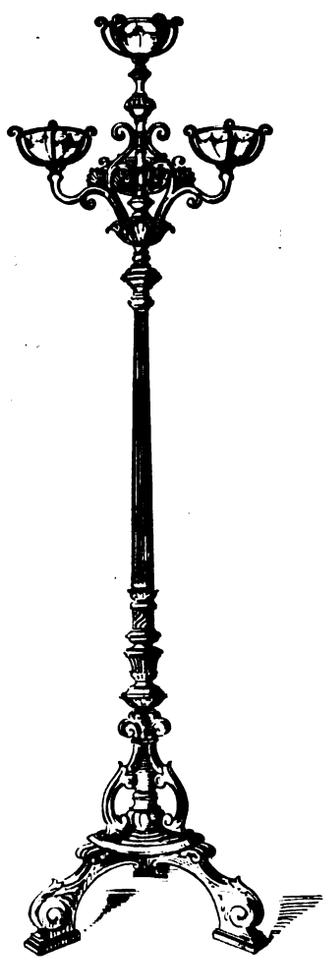

Fig. 3.—Bronze Standards for the Nave Lighting.

enable the wires to be got round the numerous angles. A large number of these iron barrels are 3in. in diameter, so that many wires can be pulled into the same tube. In the construction of the cathedral, Sir Christopher Wren left vertical shafts in a number of the main pillars, and these have been utilised for carrying up the vertical leads into the

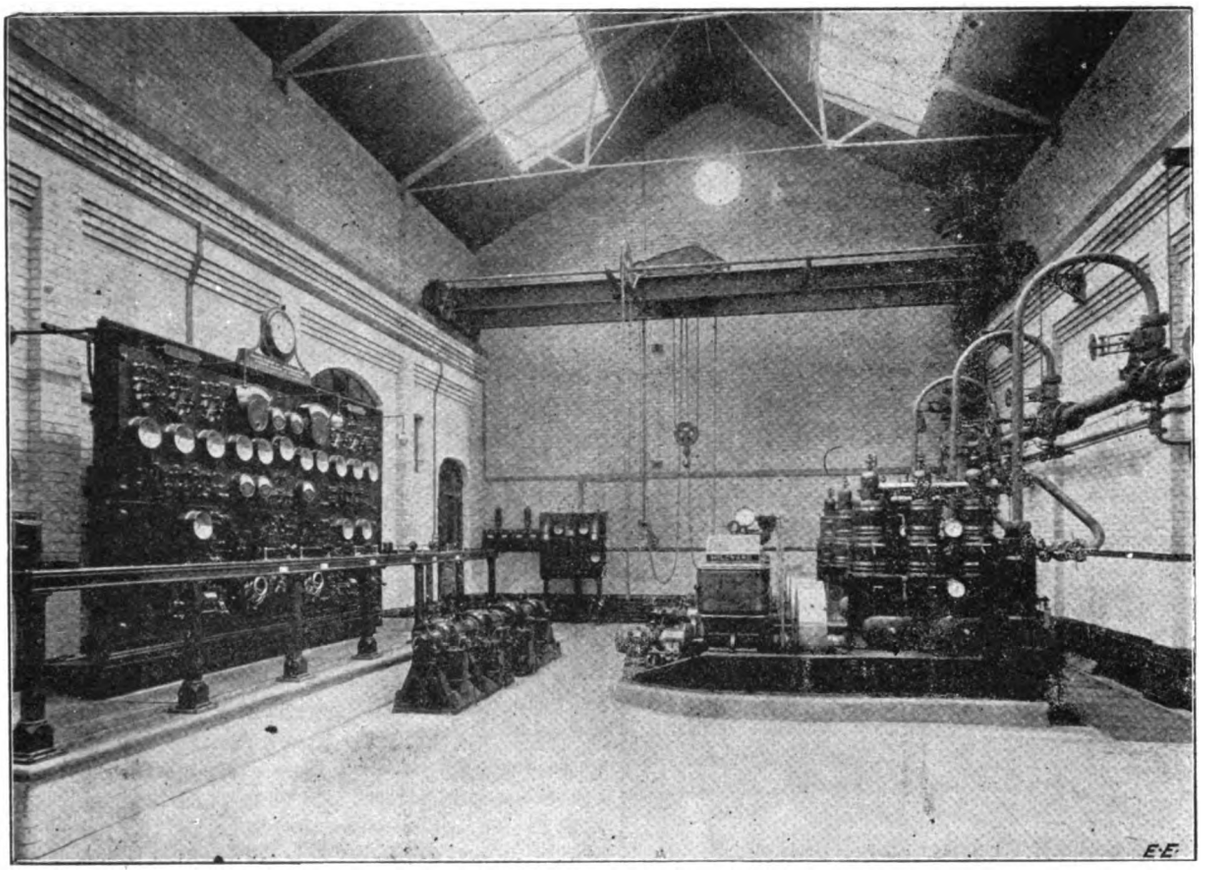
Digitized by Google

roof. The contractors for the electric lighting think that "the hollow centres of these main piers might almost have been designed for the purpose." While this is not probable, the fact remains that these vertical shafts and holes left in the roof of the chancel have enabled the work to be carried out with a minimum amount of damage to the stonework of the cathedral. Owing to the great length between the distributing boards in the crypt and the lights supplied from them hanging from the roof, the wires have to have very considerable area. We are informed that a current density of 250 amperes per square inch was adopted so as to prevent appreciable drop of voltage.

Of the lighting of the crypt we do not propose to deal in detail, but the three accompanying illustrations will serve to give an idea of the electrical fittings used respectively in the chancel, dome, and nave of the cathedral. The dimensions, however, are not on the illustrations, and in consequence one can hardly appreciate the massive character of the pendants. For instance, the fittings which are suspended from the whispering gallery of the dome in order to light the seats under the dome weigh a quarter of a ton each. These are illustrated in Fig. 1, and are cast in coinage metal and left with a scraped finish. The result is that they harmonise well with the mosaic decorations of the walls round the whispering gallery. The chancel fittings (Fig. 2) are gilded. The great weight of these hanging fittings is borne by a stranded steel armouring round the conducting wires. The outside diameter of this strand is almost 1in., and at intervals up the length of the wire ornaments are attached, which add to the general effect. The fittings are carried from the end of cantilevers inlet into the walls of the dome, and the weight is entirely borne by the steel armouring. These fittings were designed by Mr. Clarke and cast by Messrs. Benson. The nave is lighted by standards from the floor, as illustrated in Fig. 3. These exquisite bronzes are the outcome of three separate designers' labour. For instance, Mr. Penrose and Mr. Pegram were responsible for the pedestal and column, while Mr. Clarke designed the upper portion, which was cast by Mr. Benson. A great feature in the lighting is that the lamps are carried in basin-shaped glasses, which act as diffusers of the light. The glass in question is of a special texture, and is the outcome of researches on the subject by Mr. Benson. Its general appearance is not unlike in finish that of hammered metal work, and the irregular surface serves as an excellent diffuser of light, without, we are informed, unduly absorbing it. It will be remembered that the lighting of St. Paul's Cathedral is the gift of Mr Pierpont Morgan, and this gift will be more appreciated by the London public when it has been enjoyed in the winter. At present the nights are so light that one has to go to the cathedral at nine o'clock in order to judge the effect.

ALDERSHOT ELECTRICITY WORKS.

Through the kindness of Mr. O. F. Francis, the resident electrical engineer of Aldershot, we are now able to give the following photograph of the engine-room equipped under his supervision. It is not often that one photograph can be taken of the whole generating plant and switchboard to show as well as this one does the arrangements of the station. It will be noticed that the first dynamo is named "Hildyard," after Lady Hildyard, who opened the station. A full description of these works will be found in our issue of May 23.



The Engine-Room of the Aldershot Electricity Works.

Correction.—We have to correct an error which has occurred in one of our "Notes" this week, headed "The Factory Act of 1901," which, unfortunately, was not discovered until too late to delete. It seems that the deputation to the President of the Board of Trade next Thursday is not solely concerned with the effect of the Factory and Workshops Act of 1901 on the industry, but that the opportunity will be taken to lay the views of the Institution of Electrical Engineers before the President of the Board of Trade on the general subject of electrical enterprise from the point of view of legislation. We were under the mistaken impression that the deputation would merely urge upon the representative of the Government the great desirability of modifying certain of the provisions of the Factory Act in its application to electrical works.

Edison's Latest Battery.—According to a New York message, Mr. Edison claims to have solved the problem of the storage battery for automobiles. In an experimental run on Friday he is said to have made a speed of 83 miles an hour with his latest battery. For ourselves, we are not inclined to believe this in view of the numberless false rumours which obtain circulation through the daily Press on th subject. It would be well to wait for some authentic information before accepting the above statement.

ELECTROLYSIS OF MAINS (?)

In these days of specialisation it is exceedingly difficult for engineers to keep themselves fully informed on all matters connected even with their own particular branch of work. The consequence is that few find time to get more than a general idea of work outside of their own practice, and are apt to take the views of their own particular trade journal on such matters. Thus when the great question of electrolysis was discussed at the Glasgow Engineering Congress last year, the majority of the gas engineers speaking displayed a lamentable want of knowledge of the subject. They would learn much from Dr. W. Leybold's able paper which was then read on "The Destruction of Gas-Pipes by Means of Electricity," but they could not forget their preconceived ideas on the subject. This paper clearly showed that ordinary corrosion was due to electrolysis, and occurred in places where there were neither electric lighting nor electric tramways. We remember that one English gas engineer corroborated this to the disgust of the chairman. As we remarked in a leader at the time, it would be most unfair if electric tramway enterprises were called upon to make good damage done to pipes by the ordinary action of the soil. As a further evidence of how gas engineers are being educated in the matter, we give the following extracts from our esteemed contemporary the *Journal of Gas Lighting, Water Supply, etc.*, whose issue for May 27 will form amusing reading to electrical engineers. In this and previous issues our contemporary has "wiped the floor" with the English electrical papers by arguments which we should be the last to attempt to refute. Fresh from these extensive victories, our contemporary takes up the question of electrolysis of mains. The editorial article commences as follows: "The remarkable communication from Mr. Wood, of Bradford, which is noticed in another column, will serve as a further provocation to those who are charged with the responsibility of safeguarding the interests of the gas industry to give heed to the danger of electrolysis." After reading this, we naturally turn to see the communication in question. We find that the communication was a photograph, round which the editor of our contemporary had displayed his intimate knowledge of electrolysis. This photograph, to quote the description in question, "is a remarkable piece of evidence from that city as to the grave danger which is now threatening gas and water mains by the great electrical traction systems which are daily on the increase throughout the country. The gas-main illustrated is a twelve-inch one, and the two ugly, gaping apertures are the result of the fusing of an electric tramway cable on the 18th inst. The cable had been laid close to the gas-main at this point, and when it fused, Mr. Wood says, 'it melted up the earthenware pipes, bricks, and stones, but fortunately did not ignite the gas.' This shows the brilliant chance that gas-mains have in the face of an accident of this kind. The character of the holes in the gas-main are of interest. The one on the right-hand side, it will be observed, is a clean straight cut through the metal, and the aperture on the left-hand side is much of the same kind, but appears to have a good deal of surrounding fitting. The photograph was taken *in situ*. This must have been rather a troublesome job, but our illustration shows that it was very successfully accomplished. In this Mr. Wood has, indeed, done great service to the gas industry, and has supplied a strong lever with which to help forward the claim of gas undertakings to protection in connection with electrolysis. We undertake to say that more will be heard of this Bradford example of the gravity of the growing danger." This quotation shows the danger of using large words like electrolysis without,

Digitized by Google

at least, some elementary idea of their meaning. We do not propose to take up the ungrateful task of educating the editor of *Gas Lighting, Water Supply, etc.*, on this subject, but think that he should attend the lectures of the electrical experts retained by the large gas companies to report on such matters as they arise. We would point out, however, that an "electrolysis" which melts up earthenware pipes, bricks, stones, and gas-pipes is of the kind which can be easily located and removed, as at the same time it does damage to the electric cables. We should be extremely surprised to be informed that the damage to the twelve-inch gas-pipe photographed by Mr. Wood was not opened up and discovered in the course of repairing the faulty electric main. This may serve to explain why the gas was not ignited, as the melting "electrolytic" (?) process had ceased before the excavation was made which enabled an explosive mixture of gas and air to form. If this class of article is the usual literature on which gas engineers are expected to form their ideas on the subject of the electrolysis of gas and water pipes, we are not surprised at the tone of the discussion at Glasgow last year.

DUBLIN LOCAL SECTION.

The second annual report of the committee of the above section of the Institution of Electrical Engineers for the year ending this month, states that during the session nine ordinary general meetings have been held, at which various papers were read and several exhibitions of apparatus made. The committee announce that one of the members of the section, Mr. J. W. Towle, has been nominated to the Committee on Traction, Light, and Power Distribution. They have communicated with the Department of Agriculture and Technical Instruction for Ireland with reference to the utilisation of water power, asking that the Board should consider the desirability of taking some steps to secure the collection of data as to available water power at different seasons of the year, also of the sites for water power which are not at present utilised. A sub-committee has been appointed to enquire into the suggestion made in Mr. Ruddle's paper on consumers' installations. During the session 12 new members of various grades have been elected. The total membership has thus been increased from 58 to 66, at which figure it now stands.

FORTHCOMING EVENTS.

FRIDAY, MAY 30.

Royal Institution.—At 9 p.m., Prof. J. A. Fleming on "The Electronic Theory of Electricity," in place of Mr. Marconi's lecture on "The Progress of Electric Space Telegraphy," postponed till June 13.

MONDAY, JUNE 2.

Incorporated Municipal Electrical Association.—Annual convention opens in London. The convention will close on June 5.

Institution of Junior Engineers.—Visit to the new signal cabin of the South-Eastern and Chatham Railway. Meet at Charing Cross Station (under the clock) at 7 p.m.

WEDNESDAY, JUNE 4.

Electro-Harmonic Society.—At 4.30 p.m., at the Institution of Electrical Engineers, annual general meeting.

THURSDAY, JUNE 5.

Institution of Electrical Engineers.—At 12 noon, deputation to President of the Board of Trade on the subject of electrical enterprise.

FRIDAY, JUNE 6.

Royal Institution.—At 9 p.m., Sir Benjamin Baker on "The Nile Reservoir and Dams."

Engineering Standards Committee.—We are informed that the Council of the Institution of Electrical Engineers have appointed Sir Wm. Preece and Colonel Crompton to represent them on the Engineering Standards Committee.

MANCHESTER ELECTRICITY WORKS.

Very significant of the increasing demand in Manchester for electric light and electrical energy was the opening on Tuesday this week of the new electricity station which the Corporation have built on a site in Stuart-street. The new installation will, however, at first be mainly employed in meeting part of the tramway load, which naturally will become heavier and heavier as additional lines and extensions into the suburban districts of Manchester are opened up. The first instalment of 15,000 h.p. had been so far expedited as to make Tuesday's inauguration possible, and when the installation is complete the station will contain engines of an aggregate capacity of 60,000 h.p. This is provided for by Dr. A. B. W. Kennedy's scheme, under which the Electricity Committee are carrying out the work. Ultimately, however, another 12,000 h.p. will be installed under a supplementary scheme of Mr. G. F. Metzger, the borough electrical engineer. The ceremony on Tuesday consisted in starting the first engine of 2,500 h.p., a function which was very prettily carried out by Mrs. Bishop, the wife of the chairman of the Electricity Committee. After an inspection of the building had been made, the company adjourned to the town hall for luncheon, where Dr. Bishop took the chair. The toast-list was kept commendably short, the important speech being that of the Lord Mayor, who proposed success to the electricity undertaking. Speaking of the opinion expressed in some quarters that the Corporation were going beyond their bounds in assuming the responsibilities of an extensive electrical undertaking, he said it was necessary, therefore, that the greatest care should be observed in the prosecution of the work, which was of very great importance to the city, and would continue so, for the city was dependent upon the electricity department for the early use of its electric tramway system—a system that was not only a great municipal experiment, but would also be a paying one. It was only fair to say of their electrical undertaking that while there appeared to be some risks, in view of the changes and advances which were constantly being made in electrical machinery, the Corporation had as fair a chance of finding a profitable investment as had any company that had been established. In some further observations on the question of the borrowings of the Corporation, the Lord Mayor pointed out that the city was to-day indebted to the extent of 18 millions, against which they had property valued at over 23 millions sterling. In acknowledging the toast, Dr. Bishop said his committee would shortly be in a position to erect more machinery, and within six months there would possibly be six or seven engines running at the Stuart-street station. The Electricity Committee had done their utmost to push on the work in order to enable the Tramways Committee to run their cars at the time promised, and in view of the fact that the work at Stuart-street was only commenced on July 1 last, he thought that what had already been done constituted something like a record. Dr. Bishop added that during the progress of the works not a single accident of a serious nature had occurred.

FORMERS AND FORMER-WINDING.

BY F. W. DAVIES.

(Continued from page 733.)

IV. FORMERS FOR DRUM ARMATURE COILS (WIRE-WOUND).

A large variety of formers for wire-wound drum armatures has been devised The windings for them have been classified as the evolute, bastard, and barrel windings. The formers for these windings, it will be remembered, were said to belong to one of two types, the block and the frame. The evolute winding—so called from the ends of the coils being of an evolute form—is well known, though it is not so often used as the barrel winding. A serviceable former for the evolute winding is shown in Fig 7. It is of the block type, and is suitable for coils which are composed of several turns. It is of simple construction; in

Digitized by Google

fact, the block may be cut out of a single piece of hard wood. It consists essentially of the base block, A, and the raised portion, B, which is cut in the form of steps—the number of steps being one greater than the required number of turns per coil. The former shown in the figure is for coils composed of three turns. For forming the bends in the end windings, and in order that the wires may be pulled taut, the former is provided with two studs, C and C_1. There is a slight shoulder on each of these studs; and on this shoulder rests a washer, which is kept in place by a wing nut. A peg, D, is provided, so that the beginning of the wire may, by being twisted round it, be secured whilst the coil is being wound In winding a coil, the wire, after being twisted round the peg, D, is taken along the face of the block round the first stop, and then round the stud C_1. Then it is led back again on the top of the first step, round the second step, to the stud C; and thence it is taken along the face of the block round the first step in the same manner as the first turn, returning (*viâ* stud C_1) on the top of the *second* stop, and so on, until the required number of turns are wound. To render the method of winding more clear, the wires are represented in section on the steps in the end view. The coil is removed from the former after winding by removing the wing nuts and washers from the studs, C and C_1, when it can be easily taken off. A disadvantage attending the use of this design of former is that a different one is required for every different winding. Before the coils can be assembled on the armature they must be formed into the evolute shape at the ends. If the coils are but small ones, this may be done by taking the two limbs of a coil in the hands and pulling the coil into the required shape. This method does

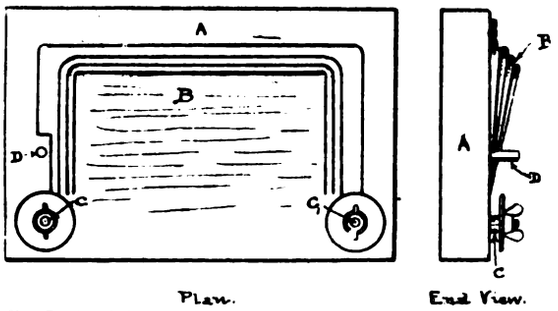

FIG. 7.—Block Former for Evolute Wire Winding. (A, base block; B, winding steps, C and C_1, studs; D, peg.)

not give it a very good shape, but it is suitable for the coils of small armatures. For the larger coils it is advisable to form the evolute spiral on the end windings by means of a second former. A former of somewhat similar construction to that used for forming the end connectors of bar-wound armatures (hereinafter to be described) may conveniently be used for doing this. There are various modifications which may be made in the construction of the block former for evolute winding, shown in Fig. 7, but the construction shown and described may be taken as a typical one

A frame former for evolute wire winding possesses the important advantage over the block former that it is possible to wind and form a coil at one operation, thus avoiding the necessity for using a second one for the purpose of forming the spirals at the end. Such a former is shown in Fig. 8, which possesses, also, the advantage that it can be used for coils having any number of turns. When it is desired to wind the coils with a different winding, the jigs, F and F_1, must be replaced with jigs suited to the new winding. The general construction of the former is made clear by the figure. The frame itself, as will be seen, is made up of two pieces of sheet iron, A and B, bent to the shape shown, and riveted together. Two angle bars of wrought iron, C and D, are screwed or riveted to the frame. In the end of each of these bars a removable peg is fitted. One of the pieces of wrought iron of which the frame is built (that marked B) has a saw-cut at each end; and the tongues of sheet iron so formed are curled up under the main bend, as shown at E and E_1. Immediately facing these tongues of metal, the jigs, F and F_1, are fixed. A detail of one of these jigs, suitable for a coil consisting of three turns, is shown in the figure. To wind a coil on this former, the end of the wire must be twisted temporarily round the fixed peg, G; and then taken over the bend on the frame A, under the peg at the end of the angle bar C, along the angle bar itself, and under the peg at the other end. From thence it is taken over the bend at the other end of the frame; and then around the largest diameter of the jig F_1, and over the bend on the frame B. The wire is then taken along the angle bar D; and, after being taken over the bend at the other end of the frame B, it is led round the largest diameter of the jig F, and over the bend on A, as at the first. This cycle of operations is repeated until the whole coil is wound.

It is not always possible in an evolute winding, especially when there is a large number of coils on the armature, to get all the bends in the end windings in place round the shaft This difficulty may be avoided by winding the armature with two sets of coils, each set consisting of half the total number of coils. Should this not meet the difficulty, the armature may be found with *three* sets of coils, a set consisting in this case of one-third of the total number of coils. Except in very rare cases, however, it will be found that the coils can be assembled in position without difficulty, if they are wound in two sets, and sometimes if wound in one set. When winding an armature in two sets, half of the coils should be wound of the usual length, and the other half of such a length that their end windings

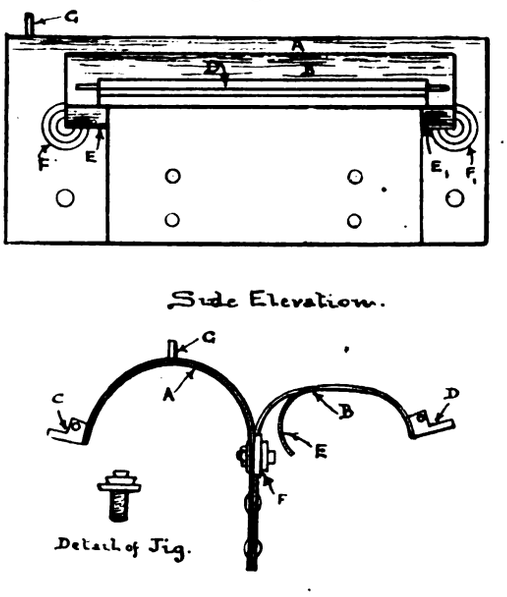

FIG. 8.—Frame Former for Evolute wire winding. (A and B, frames; C and D, bars; E and E_1, tongues of sheet iron on frame B; F and F_1, jigs; G, peg.)

project beyond the end windings of the first set. The short coils should be put on the armature core first, every alternate coil space on the core being left vacant in order to receive the long coils. When the short coils are all in position, the long coils can be placed on the core. The windings of the two sets of coils will then be in different planes at the ends. A little more room is required at the ends when this method is adopted. An armature wound thus is much easier to wind, and the insulation is safer than if wound in the ordinary way; for when the armature is wound in one set it is often necessary to use rectangular wire, or else to have a smaller number of sections in the armature, in order that there may be room for the coils at the ends. A rather serious disadvantage attending the plan of winding an armature in sets is the difficulty there is in repairing or replacing a faulty coil in the first set, if there should be one. When such a fault occurs, it is necessary to entirely remove the second set of coils before it is possible to remedy it. Also, it should be noted, two formers are required for each size of armature if wound in two sets, and three if wound in three sets. Whether or not these disadvantages are compensated for by the greater facilities for winding offered by this method, is a question that the reader must decide for himself.

The principal types of former-winding for wire-wound drum armatures, are the evolute and the barrel windings. That class of winding which belongs to neither of these

Digitized by Google

classes, but has some features in common with each, is in these articles, called the bastard winding. A block former for a bastard winding is shown in Fig. 9. The former is especially suitable for small armatures. It is simple in construction, and winding on it is an easy matter. Owing to its simplicity, skilled labour is unnecessary—a not unimportant advantage, by the way. It is made of hard wood, and consists essentially of three pieces—the back block, A (to which is fastened the centre block, B), and two end blocks, C and C_1. Passing through the back block are two bolts, the square shanks of which are recessed into the block and serve to prevent the bolts from turning. There is also a hole in each end block through which the bolts pass. The end blocks are secured to the back block by means of these bolts, on each

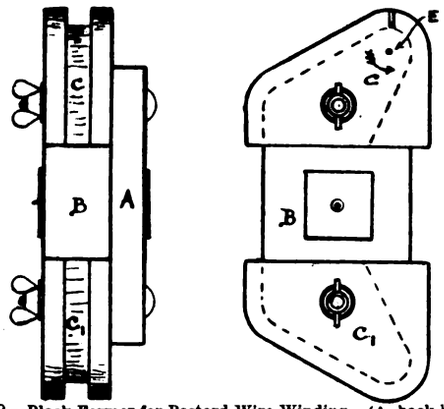

FIG. 9.—Block Former for Bastard Wire Winding. (A, back block; B, centre block; C and C_1, end blocks.)

of which a winged nut is screwed. Two small brass plates, in the middle of each of which a small hole is drilled, are screwed on to the former, so that it may be placed between centres for convenience in winding. The method of winding on this former needs, of course, no description. The method of removing the former from a coil after winding is very simple. First of all, after removing the wing nuts, the back block, A, and centre block, B, are withdrawn from the coil. Then by slightly rotating the end block C about the centre, E, in the direction indicated by the arrow, and moving it towards the middle of the coil, it can easily be removed—the end block C_1 being removed in a similar manner. The coils are mounted on the core in a precisely similar way to barrel-wound coils, the only difference between them being in the appearance of the end windings. No special end plates are required on the armature. The coils may be formed slightly with the fingers when they are being mounted on the core, though this is not really necessary. This winding is cheap, safe, and well ventilated.

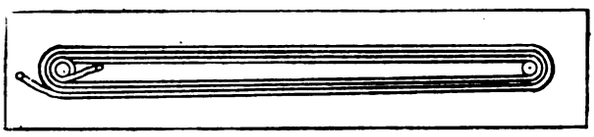

FIG. 10.—Coil for Barrel Winding, wound upon pegs, preparatory to being formed on Block Former.

The most common former-winding of all is the barrel winding. When a block former is used for this winding, it is usual to wind the coils first of all upon pegs of hard wood or metal, which are inserted into a board or into the winding bench. Fig. 10 represents such a coil, wound upon pegs, ready for being removed and formed. The forming process is carried out on a former of the design shown in Fig. 11. This former may be made from a single block of wood, but for the sake of convenience it is usually made up of several pieces. The middle of the former is quite open, as shown, in order to minimise the weight. A trough, just large enough to receive the coil, and of a contour corresponding to the shape which it is desired to give to it, is cut in this block. It facilitates matters to fasten a few clips at regular intervals near to, or over, this trough. By this means the coil may more easily be held in position during the forming process. The process of forming is a simple one. The ends of the coils are first put in place on the former, the pegs, B and B_1, being inserted in the loops at each end of the coil. Afterwards the remainder of the coil is formed by being carefully tapped into the trough with a rawhide mallet. This method of winding and forming coils for the barrel winding, though an excellent one for armatures having a large number of turns per coil, is rather more expensive in most cases than the one in which the frame former (Fig. 12) is used, as it necessitates two operations for every coil.

For medium and large sized armatures of ordinary voltage the frame former depicted in Fig 12 is the more suitable. This, as will be seen from the figure, consists of a frame of sheet iron, A, upon which is permanently fixed the hardwood block, B. The removable block, C, is held in position, whilst a coil is being wound by means of a thumb-screw and steady pins. The method of winding a coil on this former is as follows: The beginning of the coil is twisted round the fixed peg, E, and the wire is then taken around the removable block, C; and thence passes between the two removable pegs, marked

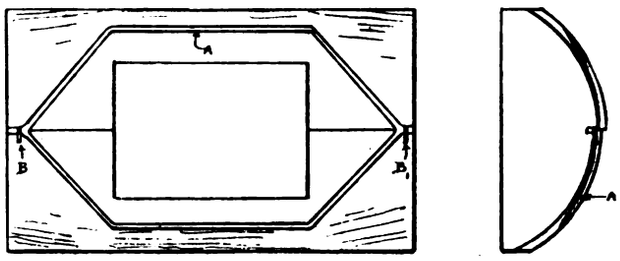

FIG. 11.—Block Former for Barrel Wire Winding. (A, coil trough; B and B_1, pegs.)

D_2 and D_3, over the edge of the iron frame, and then between the same two pegs on the other side of the frame. The wire is then taken around the fixed block, B, and is led out between the two removable pegs at the left-hand side of the former, marked D and D_1. It then passes over the edge of the iron frame, and then between the same two pegs on the other side of the frame. This completes one turn. This cycle of operations must be repeated until the required number of turns have been wound. The coil may be removed from the former by simply taking off

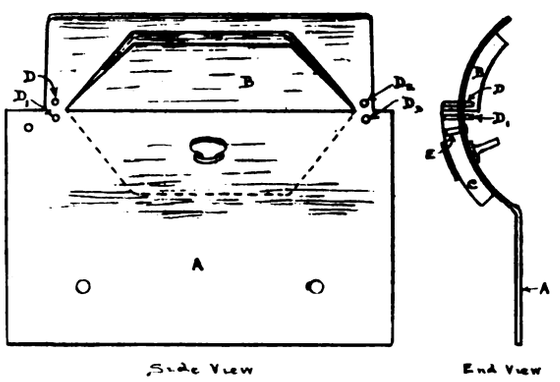

FIG. 12.—Frame Former for Barrel-Type Wire Winding. (A, frame; B, fixed block; C, removable block; D, D_1, D_2, and D_3, removable pegs; E, fixed peg.)

the removable block, C, and withdrawing the two pegs marked D and D_2. This former is a very serviceable one, and coils wound on it are both cheap and neat. Care must be exercised in the use of both this former and the frame former for evolute winding (shown in Fig. 8) not to damage the insulation of the wire where the bends occur at the ends of the coils. In all other respects, the winding of coils on this former is a matter that does not call for any special attention

(To be continued.)

PHYSICAL SOCIETY.

At the meeting of this society on May 23, Prof. S. P. Thompson, president, in the chair,

A paper by **Mr. J. A. Erskine** on **"The Conservation of Entropy"** was read by the Secretary. Heat energy may be expressed as the product of two factors—a quantity factor, entropy; and an intensity factor, temperature. The conservation of entropy holds in thermo-

Digitized by Google

dynamics when dealing with reversible processes, and is analogous to the conservation of other quantity factors, such as momentum, moment of momentum, and electric quantity. The author shows the completeness of the analogies by considering Carnot cycles carried out on electrostatic and hydraulic engines. Prof. Wiedeburg has proposed to extend the doctrine of the conservation of entropy to irreversible processes by introducing a new quantity analogous to electric resistance.

The Secretary read a letter from **Mr. Swinburne**, in which he stated that the author had got hold of what was no doubt Clausius's original idea of entropy. The science of thermo-dynamics, as far as it deals with reversible processes, depended upon what the author called the conservation of entropy, but reversible processes did not exist in practice. The author's treatment was quite in accordance with orthodox thermo-dynamics.

A paper by **Signor G. Giorgi** on **"Rational Units of Electro-magnetism"** was read by Mr. Price. Mr. Price prefaced the reading of the paper by saying that both Prof. Fleming and Prof. Fessenden had advocated a partial change of units which would leave the most important ones unchanged, and the method employed by the author was similar to that adopted by Prof. Fessenden. The author starts with a set of three equations, which contain explicitly the four concrete units of E.M.F., M.M.F., electric current, and magnetic current, together with that of activity, and considers them as fundamental in electromagnetism. Two fundamental units are required to express these quantities, and their product must reproduce the mechanical unit of activity. If the watt is assumed as unit of activity, there are two units ready made—the volt and the ampere—which satisfy the condition and may be considered fundamental. All concrete units in electricity and magnetism can be expressed in terms of these and the second as unit of time. In order to complete the system, a unit of length is required. The metre and kilogramme are consistent with the watt, and putting them together with the units enumerated in the paper, the author has built up an absolute metre-kilogramme-second system which comprises electric, magnetic, and mechanical measures in a consistent frame.

The Secretary read a letter from **Mr. Swinburne** stating that most physicists who love simplicity would be glad to get rid of "4π," but schemes for suppressing it generally moved it somewhere else. He asked if the author had really got rid of 4π, or merely chained it up in another place. If a change in units were to be made, it would be an advantage to get rid of the terms "electromotive force" and "magnetomotive force."

Prof. Everett said he had arrived at the following determinations of the author's meaning: when μ and K are taken into account we have the two following identities: (1) the dimensions of current are the same as those of magnetomotive force, or H × length, called f in the paper; (2) the dimensions of E.M.F. are same as those of quantity of magnetism divided by time—called by the author magnetic current, and denoted by g. In connection with (1) the line-integral of H for a path singly linked with a circuit carrying a current of C amperes is to be called C. This gives the unit for H in terms of the ampere and the unit of length (the metre). In connection with (2) we are to use the equation for magneto-electric induction in a circuit $\text{E.M.F.} = \frac{dN}{dt}$, together with the rule that a quantity of the magnetism m gives the total flux $N = m$. The unit quantity of magnetism is thus defined in terms of the volt and the unit of time (the second).

The **Chairman** said he had received a paper from Signor Giorgi, giving a number of illustrations of the application of his theory to calculations. There were also some further explanations, and the dimensions of many physical quantities were tabulated in terms of the volt, ampere, and second. The author claimed to have based an absolute system on the metre, kilogramme, and second, while leaving the practical units unchanged.—The society adjourned until June 13.

BUXTON ELECTRICITY WORKS.

Mr. W. J. Leeming, the borough electrical engineer, embodies in his annual report on the electricity undertaking an analysis sheet of generation and costs for the year ended March 31 last, which we give below, together with a copy of the previous year's analysis, from which the progress of the undertaking can be gauged. The engineer states in his report that the 250-kw. set had been tested, and had turned out very satisfactory. It was now running on the town, and was a very economical set. The extensions to the mains were progressing very favourably. During the last quarter 2,949 8-c.p. lamps had been connected to the mains. The analysis of generation and costs from commencement of supply to March 31, 1901, give the following figures: units generated, 102,134; total sold, 73,286; sold to consumers, 50,886; public lighting, 22,400; used on works, 16,180 (including expenditure on new machinery); per 8-c.p. lamp capacity, 12·2; maximum supply demanded, 126 kw.; number of public lamps, 25 at 10 amperes; connections to mains in 8 c.p., 6,550; capacity of plant in kilowatts, 198; load factor, 6·6; total revenue, £1,728. 12s. 9d. (5·6d. per unit); revenue from supply, £1,246. 12s. 9d. (4·08d.); from meters, £32. 10s. 5d. (0·106d.); from public lighting, £437. 10s. (1·4d.); miscellaneous, £11. 19s. 7d. (0·03d.). From April 1, 1901, to March 31, 1902: units generated, 147,563; total sold, 109,100 (sold to consumers, 86,700; public lighting, 22,400) used on works, 9,298; per 8-c.p. lamp capacity, 6·6; maximum supply demanded, 180 kw.; number of public lamps, 25 at 10 amperes; connections to mains in 8 c.p., 11,971; capacity of plant in kilowatts, 538; load factor, 6·9; total revenue, £2,496. 10s. 3d. (5·49d. per unit); revenue from supply, £1,934. 0s. 8d. (4·25d.); from meters, £50. 6s. 1d. (·1104d.); from public lighting, £500 (1·10d.); miscellaneous, £12. 3s. 6d. (0·026d).

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

485. Why is the iron regulating resistance of a Nernst lamp enclosed in a vacuum tube?—J. C. R.

486. I have two dynamos in separate engine-houses, distant about 60 or 80 yards, both compound-wound, one 200 volts, 100 amperes; the other 250 volts, 200 amperes. I might say that the engine driving the larger machine doesn't govern very accurately, the variation in voltage being as much as 15 or 20. Can I run the two in parallel at 220 volts? If so, I should like all necessary diagrams and particulars; if not, the reasons why. Of course, I mean for each machine to remain where it is. The machines are by different makers.—DOUBTFUL.

ANSWERS.

Question No. 479.—I have seen on a high-tension alternating switch-board an instrument indicating power factor, but can find in no text-book a description of its mechanism, and I should like it explained.

Best Answer to No. 479 (*awarded* 10*s.*).—Although it is not usual to meet with instruments indicating power factor, yet a great many types have been designed, several of which work very well, and are extremely useful on circuits having an induction motor load. These instruments measure the phase angular variation directly or indirectly, or what in many cases is just as good, the "wattless power." Power-factor indicators may be classified under four heads: (1) Phase meters, by which the phase angle is determined directly. (2) Power-factor meters, measuring some function of the phase angle—*i.e.*, cos ϕ, sin ϕ, or tan ϕ. Measurements involving the cosine, etc., however, are unsatisfactory if the cosine approaches unity. (3) Wattless power meters—*i.e.*, meters measuring A V sin ϕ. (4) Wattless current meters measuring A sin ϕ.

1. The best example of this group is Tuma's phase meter. A and B (Fig. 1) are two coils connected in

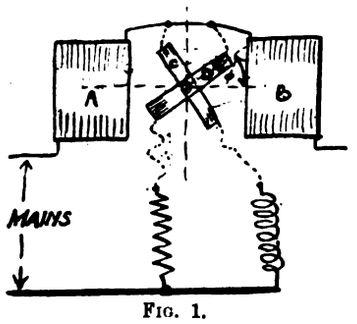

FIG. 1.

series, and carrying the current whose phase angle with reference to the E.M.F. is desired. In the field set up between these two coils, suspended freely, are two coils, C and D, consisting of two independent windings connected together mechanically at right angles. The two coils are connected across the mains separately, so that the phase of the current flowing in them depends on the phase of the voltage wave in the main circuit. One of the coils, C say, is connected in series with an inductive resistance, but the other one has a non-inductive resistance in series with it. This results in a displacement of the phase of the currents flowing in the two coils. When not in use, the axis of the coil D will lie along A B. When current is turned on it will be deflected, as shown in Fig. 1, directly the current gets out of phase with the volts. If the inductances, etc., are correctly proportioned, it

Digitized by Google

can be proved mathematically that ϕ is the actual angle of phase displacement. Another example of group No. 1 is the electrolytic phase indicator. This is a very simple device, due to Janet, and consists of a metallic drum upon which rest two styli of iron. One of these is connected so as to have a difference of potential between it and the drum which is in phase with the current. The other one is connected so that its difference of potential is in phase with the E.M.F. On the drum is stretched a sheet of paper which has been soaked in potassium ferro-cyanide and ammonium acetate. When the difference of potential between either stylus and the drum reaches a certain positive value, electrolysis begins, and the paper under the stylus turns blue. Now, if the drum be turned, each stylus traces a broken blue line on the paper, each blue mark representing part of a positive half wave. The angular distance from the centre of one of these short lines and that of the corresponding mark made by the other stylus expressed in electrical degrees is the phase angle. This, however, is only exactly true when the current and E.M.F. waves have the same form.

2. *Power-Factor Meters.*—Instruments giving trigonometrical functions of the phase angle direct are usually too involved for any but laboratory use. A Siemens electrodynamometer may be used, however, to determine them indirectly. The principle of the former is usually as follows: Two harmonic motions acting at right angles, and having the same frequency and amplitude, but a difference in phase of 90deg., will produce, if acting at the same time, a uniform circular motion. If the amplitudes are not the same the result is an ellipse, the major and minor axes of which are the respective paths of the two harmonic motions. If the phase difference is not 90deg., the two axes of the resulting ellipse do not coincide in direction with the two harmonic motions. This principle is made use of in Puluj's power-factor meter. Two electromagnets act upon two armatures, causing them to vibrate in planes normal to each other. Through one of the electro-

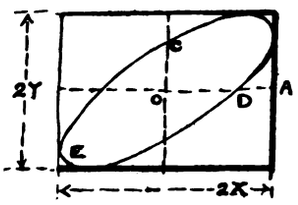

FIG. 2.

magnets is passed a current which is in phase with the current in the main circuit whose power factor we wish to measure. Through the other is passed a current which is in phase with the E.M.F. wave. A ray of light falling upon a mirror attached to one of the armatures is reflected back to a second mirror attached to the other armature, and thence to a screen. The spot of light will describe an ellipse, the shape and position of which is determined by the values of the two currents in the electromagnets and their phase difference, as in Fig. 2. Thus, if O A and O B are the directions of the two harmonic motions and C D E the ellipse described by the spot of light, it can be shown that

$$\sin \phi = \frac{O\,C}{O\,B}.$$

A method of using a modified Siemens dynamometer for phase angle measurements is described in the *Electrical World* for September, 1901. Two fixed coils are used instead of one, and the movable system is replaced by a coil closed upon itself and suspended in the plane of the other two—*i.e.*, all three coils in the same plane. Suppose that with one current flowing in one of the fixed coils, the angle of torsion required to keep the movable coil in its zero position is d_1, and with the other current flowing in the other fixed coil alone it is d_2, and with both currents flowing at the same time it is d_3. Then we have, if $d_3 = d_2 + d_1$ there is no phase displacement between the two currents. If this is not so

$$d_1 + d_2 - 2\sqrt{d_1}\,d_2 \cos\phi = d_3,$$

from which the phase angle can be deduced. In the methods described above the object sought was the determination of the phase angle. In many cases, however, we are more concerned with the magnitude of the wattless component of current than with the power factor. We may have more trouble, due to the poor regulation, caused by inductive loads than by the decrease of output and efficiency. Instruments that will measure the "wattless current," or, rather the "wattless volt-amperes," are easily made in commercial form.

3. *Wattless Power Meters.*—A Siemens dynamometer becomes a wattmeter indicating A V cos ϕ when the main current is passed through one coil, and a current proportional to and in phase with the E.M.F. through the other. If the current in the pressure coil be in quadrature with the E.M.F. the instrument indicates A V sin ϕ, the wattless volt-amperes. This is easily done with a two-phase system by taking the E.M.F. current from the other phase. With a single-phase system it is necessary to place a proper condenser or inductive resistance in series with the E.M.F. coil. The instrument mentioned in the question, however, is probably a Tuma phase meter, or one of that type.—T. SQUARE.

Answer to No. 479 (*awarded* 5*s.*).—Numerous methods and instruments have been devised for measuring the power factor or angle of phase displacement on alternating circuits, but, partly owing to their liability to inaccuracy and partly through want of simplicity in the instruments or in the methods of using them, they have not come into very general use as yet. One of the best instruments for directly measuring power factors, and one which is suitable for fixing on a switchboard, is that made by Messrs. Hartmann and Braun (Tuma's principle). It may be used on single, two, or three phase circuits, and its readings are not rendered inaccurate by small changes in periodicity. It consists (Fig. 1) of a single fixed coil carrying the main

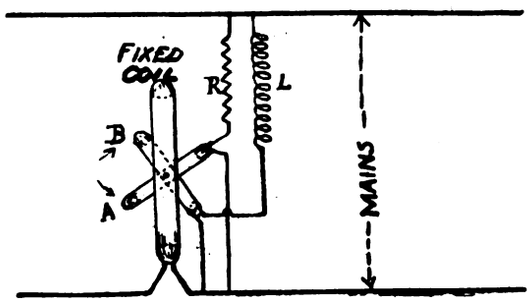

FIG. 1.

current of the circuit (or at least a derived current in phase with the main current), and two swinging coils, A and B, fixed at right angles to each other and on the same suspension. The fixed coil surrounds the swinging one. The two swinging coils are connected in parallel with one another across the mains, with the difference, however, that one is in series with a large non-inductive resistance, R, whilst the other is in series with a highly inductive choking coil, L. In this way both moving coils are made to carry the same amount of current, but that in one coil, B, lags practically 90deg. behind that in the other, A. The two coils consequently act just like the two sets of stator coils in a two-phase induction motor, and produce a rotating magnetic field. Under these circumstances as soon as the main current is passed through the fixed coil, the moving-coil system will take up such a position that the rotating field is exactly parallel to the fixed coil's field at the instant when the latter is a maximum—*i.e.*, when the current in the mains is a maximum. Thus, suppose the circuit voltage and current to be exactly in phase, then, at the instant when the current in the fixed coil is a maximum, the current in the non-inductive coil, A, will also be a maximum, whilst the current in coil B (which lags 90deg. behind that in A) will be zero, and the direction of the rotating field at the instant will, therefore, be parallel to the axis of A. Consequently the swinging coils will set themselves so that the phase of coil A is parallel to the plane of the fixed coil. The corresponding position of the pointer of the instrument would be marked 1 on the scale—*i.e.*, the power factor of the circuit = 1 when the pointer is at this point.

Next, suppose the load on the circuit to be practically

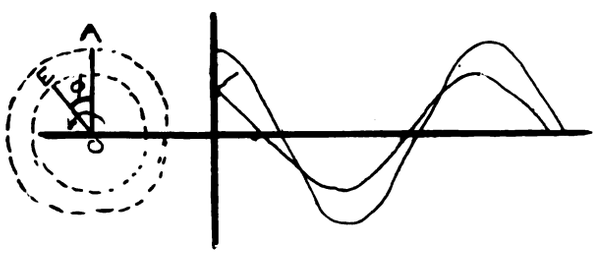
Digitized by Google

entirely inductive, so that the current lags 90deg. behind the voltage. Then, at the instant of maximum current in the fixed coil, the current in coil A will be zero, whilst that in coil B will be a maximum, and the rotating field will be in the direction of the axis of B. Consequently the position taken up by the swinging coils will be such that the plane of coil B is parallel to that of the fixed coil—*i.e.*, 90deg. from the position occupied in the previous case—and this position of the pointer would be marked O. In the same way, the coils would take up some intermediate position for all intermediate values of the angle of lag, the resultant instantaneous field due to the combined action of A and B being nearer to the direction of the axis of B or to that of A according as the load is more or less inductive. For angles of lead (capacity loads) the coils would move in the opposite direction from the point for non-inductive load (marked 1), so that the complete scale of the instrument would cover an angle of 180deg., with the centre point marked 1 and the two end points marked "O lagging" and "O leading" respectively.

Of other instruments for the same purpose reference may be made to that of the Allgemeine Electricitäts-Gesellschaft, of Berlin, in which the measurements are proportional to volts × amperes × sine of angle of lag or lead, and which is practically a small two-phase induction motor, one phase of which is excited in series with the mains and the other in shunt to them. The two coils are fixed, and surround a suspended short-circuited rotor controlled by a torsion spring. So long as the volts and amperes are in phase the coils only give rise to a stationary alternating field, but as soon as any phase difference occurs a rotating field is produced and a torque is exerted on the rotor. This instrument, however, does not give the value of the power factor directly. The General Electric Company of America have introduced a phase meter, for use on balanced two or three phase circuits, which is based on the fact that the readings on two wattmeters having their shunt coils placed respectively across two of the phases and their series coils placed in series with the line common to these two phases, will bear a ratio to one another proportional to the phase angle between volts and amperes in each phase. Instead of two actual wattmeters a single instrument is used, having one series coil and two shunt coils attached to the same suspension. This instrument, again, only gives the power factor indirectly, but both this and the Allgemeine Electricitäts-Gesellschaft one described above are quite suitable for use with rotary converters and synchronous motors for the purpose of deciding the correct excitation to obtain a power factor of unity, for the instruments deflect one way or the other according to whether the current leads or lags.

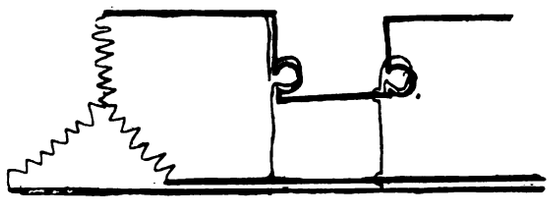
A classification of the different possible instruments for use as phase meters, together with some particulars as to their accuracy, will be found in a paper read by Prof. W. Browne before the American Institute of Electrical Engineers in June, 1901, and abstracted in the *Electrical World* of New York for Sept. 7, 1901 (p. 379).—Q.

Answer to No. 479 (*awarded* 5*s.*).—In the case of a continuous current the power absorbed by a circuit is equal to the product of the volts at its terminals into the current



passing. But in the case of an alternating supply this is only true when the current is in the same phase as the pressure—that is, they have their zeros and maximum values simultaneously. This can best be represented by the accompanying diagram. Let O E represent the voltage, and O A represent the current lagging by an angle ϕ. The power absorbed in the current is equal to the product of the voltage, O E, into the component of O A in phase with it—that is, power = O E . O A cos ϕ—and this factor, cos ϕ, is what is known as the "power factor." Its value is from 1 downwards, and for maximum power from a line whose maximum current is fixed it should be 1, for the smaller it is the greater the current for a given power, and consequently the greater heating loss in the cables. In working synchronous motors it is well to have an indicator of power factor, as by varying the excitation the current can be made to fall into phase with the pressure, and so economy may be effected.

The design of a commercial power-factor indicator is a problem that has occupied some attention for a considerable time, and it can safely be said that the instrument in its most general form has yet to reach perfection—in fact, up till now there is no instrument sold which will directly indicate the phase difference between the pressure and current in one circuit. To measure in the laboratory the lag of a current it is usual to take three independent readings, one from a wattmeter (of the split-dynamometer type), and one each from a voltmeter and ammeter. The product of the latter gives the *apparent watts*, and the former the *true watts*, the ratio between these being the power factor. This is an operation which could scarcely be performed mechanically. There are several laboratory instruments which are made to read off power factor, but as in nearly all some preliminary adjustment has to be made they cannot be called switchboard instruments. Thus there are many depending on the magnetic field set up by the currents flowing in the two coils, one current being in phase with the pressure and the other with the main current. But in all of these it is necessary to adjust the shunt so that there will be equal currents flowing in both coils, or the power-factor reading will be completely masked. Instruments such as the oscillograph, which give the actual relative positions of the curves of pressure and current, will also indicate with considerable accuracy the lag of the current behind the pressure, but these again are not exactly commercial types.



Though for the determination of power factor in one circuit the problem presents such difficulty, yet when we come to three-phase working (such as was probably the case mentioned by your correspondent) it is greatly simplified if a wattmeter be inserted in one of the leads of a three-phase line and one end of the pressure coil being connected to the same lead, the other end of the pressure coil being connected first to one of the other leads and second to the remaining one. If d_1 and d_2 are the deflections of the instrument, then it may be shown that if ϕ be the phase angle of the current behind the pressure (assuming this to be equal in all three circuits)

$$\tan \phi = \sqrt{3}\left(\frac{d_1 - d_2}{d_1 + d_2}\right).$$

This fact is the principle of an instrument which is on the market. It consists of two split-dynamometer wattmeters; the current coils in series with one lead; the pressure coils between this lead and the other two; the connections made so that the torques oppose, and the two movable coils on one spindle, to which is attached the pointer. The instrument will be calibrated by comparison with the three readings method of the laboratory. The pointer marks unity power factor in the middle of its scale, lag and lead being shown by deflections to opposite sides.—T. R. S.

Question No. 480.—Describe, with sketches and diagram of connections a good type of series-parallel controller for electric overhead travelling crane.

Best Answer to No. 480 (*awarded* 10*s.*).—Controllers are now either of the magnetic or solenoid type. They are both largely used, the latter being used on many corporation tramway installations. It is perhaps more effective than the other, having a solenoid at each contact, and so reduces the damage done by flashing. The general

Digitized by Google

arrangement of a series-parallel controller and a complete diagram of connections is shown in Fig. 1, the mechanical detail of which needs but little description. It consists of a vertical spindle with rows of metal projections, on which are fixed renewable contact pieces, this spindle being operated by means of the controller handle, and when the latter is revolved these contact pieces make connection with a number of metal strips fixed on the side of, and thoroughly insulated from, the case of the controller. There is also a small power handle which operates the reversing switch for the motors, on the spindle of which is fitted an interlocking arrangement so that the controller handle cannot be moved when this power handle is in the "off" position. There are two other small switches, which in case of one motor being disabled allows that motor to be completely disconnected from the circuit and the crane can be worked *pro tem.* with the single motor. A short description of the electrical arrangements and connections is also interesting. On one side of the controller are a number of terminals (shown on the right-hand side of Fig. 1) from which the motor leads are taken, short leads to the contact strips (shown on the left of the sketch), leads to the resistances, which are usually placed in some convenient place away from the controller, short connecting strips to the reversing switch terminals, and the mains from the trolley wires. In the sketch the return main is shown "earthed," but this is only a detail. The upper five rows of projections are all fixed on to one casting, the next three rows to another casting. These two and the bottom casting, which is shown connected to the controller frame (or some other convenient earth connection), are all

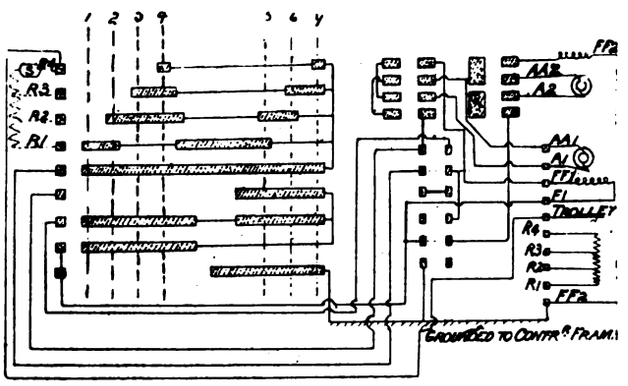


FIG. 1.

thoroughly insulated from one another, and fixed on to the controller spindle. I have for the sake of simplicity shown the electrical contacts supposed to be laid out flat; the lines drawn from one projection to another on the same row are merely to remind one that they are all on one casting. For the same reason have I shown the ends of these rows connected. When the power handle has been put into, say, the position for "hoist" and the controller handle moved over to stop No. 1, the two motors are connected in series with all the resistance in the circuit, and as the handle is moved over the stops 2 and 3, the resistance is gradually cut out of the circuit until it reaches No. 4, when the two motors are connected in series with all resistance "out." When the controller handle reaches No. 5 stop, then the two motors are in parallel with a portion of the resistance in circuit, and, as before, is gradually cut out until finally, when on No. 7, all the resistance is cut out and the motors connected in parallel across the mains. Between the stops 4 and 5 the change from "series" to "parallel" is made. First, a point between the field coil of No. 1 motor and No. 2 armature is earthed (in the case of an earth return). Now No. 1 motor is doing all the work. Then the armature connection of No. 2, which is connected at this point, is then, as the handle is moved round, connected to the armature lead of No. 1, thus putting the two motors in parallel, but at the same instant all the resistance is placed in series with the main circuit. But when the handle reaches No. 5 stop only a portion of the resistance is in circuit. By a little study of the sketch these changes will be easily followed. Fig. 2 shows a simple arrangement of the reversing and motor cut-out switches. The main current after passing through the resistance enters No. 1 motor armature at the terminal marked A A_1, and in No. 2 motor at A_2. When the switch is reversed the current will then enter No. 1 at A_1, and No. 2 at A A_2. The direction of the current in the field coils in each case is the same. When the motor cut-out switch, M S_1, is in the downward position it will be seen that the current will pass straight on by means of the short-circuit strip at the bottom of the switch on to No. 2 motor, and thus cutting out No. 1 from the circuit, and in cutting out No. 2, the switch being in the downward position, the current after passing through No. 1 motor would be earthed direct. For a more detailed description of various other

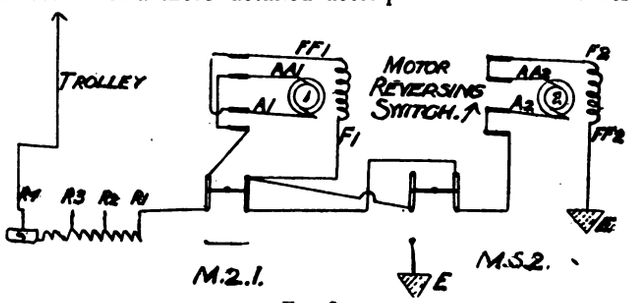

FIG. 2.

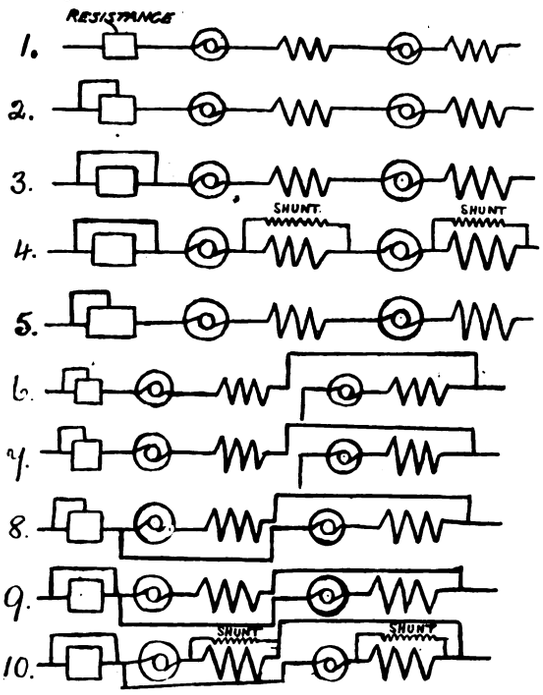
types of controllers aud their electrical arrangements I think I can only recommend anyone who may be interested with such electrical equipments to look up the *Electrical Engineer*, vol. xxiii., p. 339; vol. xxvii, p. 117; and vol. xxviii., p. 519.—A. G. SHEARER.

Answer to No. 480 (*awarded* 5*s.*).—The series-parallel system consists in the use of two or more motors, which by means of a special device are thrown into different combinations. The sketches below show the various relative positions through which the motors pass from their first position, when they are in series with a resistance thrown in, to their last position for high speeds, where they are in parallel and part of the field is cut out, this accelerating the motors.



The following are the various positions in what is known as the "K" controller of the General Electric Company: (1) motors in series and all resistance in circuit; (2) motors in series and half resistance in circuit; (3) motors in series and all resistance cut out; (4) motors in series and shunt around the fields; (5) same as position (2); (6) one motor cut out, the other in series with half the resistance; (7) same as (6); (8) motors in parallel with half the resistance in series; (9) motors in parallel with no resistance in series; (10) motors in parallel with shunt round field.

The points (5), (6), and (7) are only graduating. The four economical running speeds are when the controller is in the positions (3), (4), (9), and (10).—H. TAYLOR.

TUBE BILLS IN PARLIAMENT.

LORD WINDSOR'S COMMITTEE.

MONDAY, MAY 26.

The Select Committee of the House of Lords presided over by Lord Windsor reassembled in the Grand Committee-room, Westminster Hall, after the Whitsuntide recess, and proceeded with their consideration of the schemes of the combined Piccadilly and City, London United, and North-East London Railways for an underground railway from Hammersmith to the City.

Mr. Fitzgerald, K.C., for the Central London Railway Company, whose proposal for the construction of a new tube from Hammersmith to the Bank was, with the exception of a small loop at the City end, rejected by the committee at the last sitting, said all it was proposed to proceed with in their Bill was the provision for the acquisition of land for the enlargement of their station at Marble Arch. This land was the property of the Duke of Portland, and its acquisition was not opposed. They also asked for power to raise the sum of £150,000 new capital for the acquisition of land and the construction of rolling-stock.

The committee passed the preamble of the Bill so far as it related to these matters.

Mr. Balfour Browne, K.C., said that since his withdrawal of the Bill of the City and North-East Suburban Company for the construction of a line from Whitechapel to Waltham Abbey the local authorities had approached them with a request that they should proceed with their railway, believing that some means would be found hereafter of getting from Whitechapel into the City by an unobjectionable route. Messrs. J. S. Morgan and Co. had agreed to give financial support to the line. He desired to ask the committee whether, if he succeeded in getting the order of the House of Lords for the withdrawal of the Bill discharged, they would hear him in support of their proposal.

Mr. Littler, K.C., for the North London Railway, protested against this "extraordinary application."

The **Chairman** said the committee could not give any support to the application.

Mr. Balfour Browne said he believed the only opposition remaining to be heard against the combined line from Hammersmith to the City and to Palmer's Green was that of the frontagers, and the promoters had framed a clause expressing their view as to how the frontagers ought to be dealt with. The clause was drawn on the lines suggested by Viscount Knutsford so as to place for a limited period after the opening of the railway the owners of lands and houses which were not taken on the same footing as the owners of lands and houses which were taken for the purposes of the railway. The words "injuriously affected" had been incorporated in the clause in accordance with the suggestion of Viscount Knutsford, and he believed that by its terms the views of the committee would be carried out.

The **Chairman** expressed a hope that the clause would be considered by all the parties interested, so that on Friday, when they would take it into discussion, it might be possible to arrive at a settlement.

In reply to a question by Mr. Pember, K.C., with regard to the North-East London Railway, the Chairman said they would not give their decision on the preamble until the whole of the opposition to the combined scheme had been heard, but if there were nothing else but the railway opposition the committee would pass the preamble.

Mr. Reader Harris, K.C., addressed the committee on behalf of the frontagers along Kensington-gore and in Prince's-gate in opposition to the railway.

Lord R. Cecil, K.C., stated the opposition of the rectors and churchwardens of St. Martin's-in-the-Fields and St. Clement Danes, Strand, to the railway, which passed close to both those churches.

The committee having consulted in private,

The **Chairman** said the committee had decided to pass the preamble of the Bill for the construction of a railway from Hammersmith to Palmer's Green. The committee would next proceed with the Clapham Junction to Marble Arch Railway.

Mr. Balfour Browne said there was no opposition to this railway, Earl Cadogan, the Duke of Westminster, and the Battersea Borough Council having been settled with.

The committee then declared the preamble to be proved, and also made the same declaration with regard to the extension of the Brompton and Piccadilly-circus line to Holborn, to which there was no opposition.

Mr. Littler applied for an extension of time for the construction of the authorised Brompton and Piccadilly-circus Railway, which was granted, and the committee adjourned.

TUESDAY, MAY 27.

The committee proceeded with the opposition to the proposal of the Brompton and Piccadilly-circus Railway Company for the construction of a spur line from South Kensington to Parson's-green *vid* Fulham-road. The general scheme was explained to the committee a week or two ago.

Mr. Freeman, K.C., now addressed the committee in opposition to the proposed spur line on behalf of the Brompton Consumption Hospital and other institutions on the line of route. He explained that it was proposed to construct the railway with a station in the immediate neighbourhood of the consumption hospital. These buildings were of a very special character, and he submitted that there was no public necessity shown for this railway. Another scheme was also before their lordships' committee for the construction of a railway under the King's-road, Fulham, which was not open to the objections, from the point of view of the hospitals, of the railway now under consideration.

Evidence having been given in support of counsel's statement,

Mr. Coward, K.C., on behalf of the London County Council, asked the committee to reject the proposal, which they regarded as unsatisfactory from the point of view both of finance and of convenience to the public. But the real fear of the County Council was that, if sanctioned, the railway would never be made, but would remain as a "block" line against any other railway down either the Fulham-road or the King's-road.

The **Chairman** said the committee had decided that this portion of the preamble of the Brompton and Piccadilly-circus Railway Bill had not been proved.

The committee next proceeded with the King's-road Railway Bill.

Mr. Balfour Browne, K.C., explained that the Bill was before the Joint Committee last year, and that their report was that it might be referred in the ordinary course "if interchange stations are provided at Victoria; an extension to Putney would be desirable." Last year, the proposal was to proceed only as far as Eel Brook Common, but in accordance with the recommendation of the Joint Committee the present scheme was to construct a line from Putney, starting close to the station of the London and South-Western Railway there, coming under the river on to Eel Brook Common, and so on to Victoria. There it was proposed to make an exchange station which would enable passengers to get into the City in conjunction with the Deep-Level District Railway. The line was four miles one furlong in length, and was supported by all the local authorities through whose district it passed except that of the city of Westminster. The capital proposed by the Bill was £2,598,773, and the promoters believed there would be no difficulty whatever in raising the money.

Mr. J. MacAllister, one of the promoters, gave evidence in support of the Bill. He said the estimates provided for a sum of £123,000 for financial purposes. In cross-examination, the witness stated that the other promoters were Sir Owen Slacke, Sir Richard Sankey, and Lord Teynham.

Mr. Shepherd, of Messrs. Shepherd, Perry, and Scott, financiers, Old Broad-street, thought there were fair prospects of raising the capital in the City.

The **Chairman**, on receiving an intimation that this was all the direct evidence as to finance, said the committee did not think that the preamble of the Bill was proved.

Mr. Pember said his clients, the governors of St. George's Hospital, had been informed that the West and South London Junction Railway Bill, which stood next on their lordships' list, was to be withdrawn. They thought it was a gross abuse that a Bill should be kept in the list until the last moment, and that then, when all the expense had been incurred by the opponents, it should be withdrawn. He asked the committee to keep a grip on the Bill until Friday, when he should ask their lordships to award his clients cost against the promoters.

The **Chairman** said the committee would take care that the Bill was not withdrawn behind the backs of those interested in it as opponents.

The committee adjourned till to-day (Friday).

NEW COMPANIES REGISTERED.

Anglo-French Motor Syndicate.—Capital £10,000. Object: to acquire and work a motorcar business as now carried on at Suresnes, France, and elsewhere.

Electro Voelker Syndicate, Limited.—Capital, £5,000. Objects: to adopt an agreement with E. Manning and William Barker, and to carry on business as sanitary and electrical engineers, etc.

Anglo-Belgian Construction Syndicate, Limited. — Capital, £50,000. Objects: to construct, equip, and work rail and tram roads, light railways; as producers and suppliers of electricity for the purposes of light, heat, or power; establish and maintain telegraph and telephone systems, etc.

Dunlop Marine Course Signal Syndicate, Limited.—Capital, £5,000. Object: to acquire any inventions relating to marine signalling and apparatus therefor; in particular, to acquire an existing invention from J. D. Dunlop, and to carry on the business of electrical and general engineers, etc.

Bohm Syndicate, Limited.—Capital, £35,000. Objects: to acquire any patents relating to improvements in the manufacture of electric incandescent lamps or any other patents; in particular, to acquire from M. Boyd, of 147, Fenchurch-street, the benefit of certain existing inventions in relation to the above, etc.

City and Surrey Electric Railway Company, Limited.—Capital, £150,000. Objects: to carry on the business of an electric railway company, to undertake the construction, maintenance and working of electric and other railways and tramways and motors therefor, and their accessories and appurtenances, etc.

Erimus Automatic Safety Guard Company.—Capital £2,000. Objects: to acquire the benefit of a certain existing invention in relation to an improved form of safety guard for tramcars, motorcars, and the like; and to adopt an agreement with Middlesbrough Investments, Limited, and others generally to acquire any other inventions relating to safety guards or other machinery, accessories, or fittings to electric tramcars, trolley and motor cars, vans, carriages, and other road vehicles, etc.

APPOINTMENTS VACANT.

Draughtsman for electrical measuring instrument department. Ferranti Limited, Hollinwood, Lancashire. See advertisement.

Borough Electrical Engineer and Tramways Manager, Newport (Mon.) Corporation, May 31. Full particulars may be obtained from the town clerk.

Commission Agents, to travel in Manchester, London, Midlands, North and South of England, Scotland. A. Royle and Co., Sutton Oak, St. Helens. See advertisement.

COMPANIES' MEETINGS AND REPORTS

WOKING ELECTRIC SUPPLY.

The annual general meeting of this Company was held at Woking on Saturday, Mr. John Ashby presiding.

The directors' report stated that the revenue earned from sale of current and rent of meters amounts to £4,466. 15s., as compared with £4,002. 5s. 11d. in 1900. Taking into consideration the fact that the Company ceased to supply current for the public lamps in May of year under review, and that the Inkerman Barracks were unoccupied for the latter half of the year, and consequently consumed very little current, the directors consider the increase in revenue very satisfactory. Further, taking into consideration the fact that the full benefit now being derived from the new plant did not obtain until late in the year, on account of the delay in delivery by the makers, they feel that the present year will show a very much better result. At the beginning of 1901 the total number of lamps on circuit was 11,400 ; this figure had increased at the end of the year to 15,090, and had further increased at the end of March to 15,889, while the number of customers increased during the year from 294 to 417. The directors consider that this steady increase is very encouraging, and augurs well for the future of the Company. It may be mentioned that the present plant is sufficient to supply 21,500 lamps without any further additions. During the year 43,875ft. of additional new cable have been laid, and 6,926ft. of new cable have been laid to replace old, and it is believed that these new cables have tapped districts which will ere long give an adequate return on the capital expenditure involved. It will be seen from the balance-sheet that during the year £3,400 4½ per cent. debentures and £8,790 6 per cent. cumulative preference shares have been issued to provide funds to meet the expenditure upon new machinery, boilers, and new cables, and generally for the increased requirements of the Company. The directors have pleasure in recording the excellent work done by Mr. J. G. McLean, the Company's engineer and manager, and they consider that the success achieved during the year is largely due to his energy and tact.

The **Chairman**, in moving the adoption of the above report, said that when the present directors took over the management of the Company it was not in a satisfactory condition, most of the mains being rotten, and the dynamos and boilers out of date. Last year they called for fresh capital in order to buy new plant, which they anticipated would be delivered early in the year. There was, however, great delay with the makers, and they did not get the new boilers until Nov. 1 and about a fortnight before Christmas. Hence they were working under a serious disadvantage, and at heavier cost than would have been the case had the plant been delivered sooner. They had now got quite an up-to-date plant, and the majority of the mains were new and in good order, so that the Company were in a position to supply light to the inhabitants of Woking in a thoroughly satisfactory manner. The present number of lamps was 16,252, and 800 more were waiting connection, so that by that day fortnight they would probably have 17,000 lamps on circuit. The number of customers at present was 460.

The report and accounts were adopted.

CORK ELECTRIC TRAMWAYS AND LIGHTING.

The following is the balance-sheet of the above Company for the year ended Dec. 31 last :

To nominal capital : 11,500 5 per cent. cumulative preference shares of £10 each, £115,000 ; 11,500 ordinary shares of £10 each, £115,000—£230,000. Issued capital : 11,000 5 per cent. cumulative preference shares, £110,000 ; 11,000 ordinary shares, £110,000—£220,000 ; less calls unpaid, £435—£219,565. Reserve account : premium on shares issued, £2,000 ; 4 per cent. mortgage debentures, £70,000 ; interest accrued on mortgage debentures, £1,318. 6s. 8d. ; loans, £20,484. 8s. ; sundry creditors, £9,792. 7s. 11d. ; reserve for depreciation, £2,000. Profit and loss account : balance Dec. 31, 1900, £6,916. 6s. 10d. ; less dividends and other appropriations thereout, £6,665. 16s.—£1,250. 10s. 10d. ; and profit for year as per annexed account, £9,426. 12s. 2d.—£10,677. 3s. ; less interim dividend on preference shares to June 30, 1901, £2,500—£8,177. 3s.—£333,337. 5s. 7d. By capital expenditure as allocated by the engineer : land, £2,877 ; purchase and cost of Order in Council, £13,526. 0s. 6d. ; buildings, offices, and plant in power house, £71,584. 1s. 5d. ; permanent way, rolling-stock, overhead line, etc., £129,114. 11s. 9d. ; house services and lamps on consumers' premises, £12,550. 5s. ; cables, £57,433. 0s. 6d. ; public lamps and cables, £5,682. 19s. 10d. ; Queenstown lighting undertaking, £21,950. 12s. 9d.—£314,718. 11s. 9d. Stores on Company's premises, £5,548. 19s. 7d. ; work in progress—installation of motors, £707. 1s. 6d. ; plant on loan, £502. 9s. 8d. ; office furniture and fixtures, £429. 0s. 10d. ; sundry debtors, £10,487. 12s. 9d. ; cash at bankers and in hand, £243. 9s. 6d. ; preliminary and establishment expenses—amount as per last balance sheet £750 ; expenditure during year, £176. 0s. 9d.—£926. 0s. 9d. ; less written off, £226. 0s. 9d.—£700—£333,337. 5s. 7d.

BARCELONA TRAMWAYS.

The directors' report for the year ended Dec. 31 last states that the traffic receipts from electric traction amounted to £105,641, and sundry receipts £773, making the total receipts £106,235. The working expenses were £70,035, leaving a gross profit of £36,200. Deducting loss on exchange, and adding amount carried forward from 1900, there is a balance of £25,973. The receipts show an increase over those of 1900 of £6,714, and the expenses only £306. The number of passengers carried was 33,787,925, against 27,959,547 in 1900 and 21,736,264 in 1899. The balance at credit of net revenue account is £25,973 ; of this amount the service of the debentures and debenture stock has absorbed £10,264, and the dividend on the preference shares £5,000. The directors now recommend the payment of a dividend on the ordinary share capital at the rate of 3 per cent. per annum, free of income tax, and that the sum of £4,709 be carried forward. The Board's reason for carrying forward so large an amount is that a sum of £3,316, paid to the Spanish authorities in respect of arrears of taxes for 1899-1900, has been temporarily carried to a suspense account. A considerable portion of this amount is in dispute, and has been appealed against ; pending a final settlement, the directors thought it prudent to make provision for the entire sum, in case the Company's appeal is unsuccessful. The conversion of the Ensanche line, and the construction of the Josepets-Bonanova extension, together with the supply of 40 addditional motorcars (26 new and 14 converted), will, when completed, entail an expenditure of about £65,000, of which the sale of certain sites of stables and car-sheds no longer required will produce about £10,000, and it is proposed, towards providing for the remainder, to issue the hitherto reserved balance of the 4½ per cent. redeemable debenture stock, amounting to £51,900.

INSTITUTION OF ELECTRICAL ENGINEERS.

At an extraordinary general meeting of the Institution on May 15 the following were the candidates balloted for :

Associate Members.—G. Aldridge, 7, West Marlands, Southampton ; W. Hudson, 9, The Drive, West Brighton ; W. F. Long, 2, Albany-road, Chorlton-cum-Hardy, Manchester ; J. D. Pember, 99, Bridge-street, Farnworth.

Associates.—A. D. Manlove, Little Dene, Ventnor, I.W. ; A. Ruiz, Los Andes, Chili ; B. Sankey, 306, Markhouse-road, Leyton ; E. Thornton, 86, Charing Cross-road, W.C. ; C. J. Vaughan, General Post Office, Durban.

Students.—D. C. H. Bell, 9, Powis-gardens, W. ; C. Petersen, 3, Aynhoe-road, Brook Green, W. ; P. Richards, Dunkeld, The Avenue, Beckenham.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Falkirk.—The Town Council will shortly advertise for tenders for piping and cables.

Shanghai.—The last day for receiving tenders for the proposed municipal tramway and motor 'bus service is June 30.

Beckenham.—The Electric Lighting Committee invite tenders for the supply of incandescent lamps. Tenders by June 6.

Dudley.—The Electric Lighting Committee invite tenders for the supply of incandescent lamps and oil. Tenders by June 6.

Sophia (Bulgaria).—The General Post Office require tenders for £2,000 worth of telephone and telegraph material. Tenders by June 9.

Glamorgan.—Tenders are invited for wiring and fittings at Parc Gwyllt and Angelton Asylums, near Bridgend, Glamorgan. Tenders by May 31.

Calarashi-Stirbein (Roumania).—The Municipality invite tenders for the installation and working of electric lighting for 35 years. Tenders by June 13.

Dunston. — For relighting the Primitive Methodist Church. Applications to be made personally to Mr. A. Scott, Winship-street, Dunston, by May 31.

Fulham.—The Board of Guardians invite tenders for the supply, delivery, and erection on their premises of pipework. Tenders by June 5. See advertisement.

Glasgow.—The Corporation invite tenders for the supply of electricity meters required for the year from June 4, 1902, to May 31, 1903. Tenders by June 7. See advertisement.

Greenock.—The Corporation invite tenders for the supply and erection of one 300-kw. steam dynamo, with steam and exhaust piping. Tenders by June 2. See advertisement.

Rome.—The Minister of Marine and the Director of the Arsenal at Spezzia invite tenders for about £5,000 worth of electrical material for installations on men-of-war. Tenders by June 4.

Valparaiso.—The Municipality are inviting tenders for electric lighting and tramways. We understand that particulars may be obtained from the Chilian Consul. Tenders by Sept. 1.

Bury.—The Tramways Committee invite tenders for the supply and delivery of rails and fishplates, fishbolts and nuts, tiebars, points and crossings, and sole or anchor plates. Tenders by June 24.

Barking.—The Urban District Council invite tenders for motors, pipework, chequer plating, etc. Full particulars may be obtained from the Engineer, Electricity Works, East Barking. Tenders by June 6.

Brighton.—The Town Council invite tenders for the supply of 300 tons of steel girder tramrails. Specifications, etc., may be obtained from Mr. Thos. B. Holliday, tramways engineer, Lewes-road, Brighton. Tenders by June 9.

Lisbon.—The Portuguese Government Railway require 34,300 kilos of 1, 2, 3, and 4 mm. galvanised wire. Tenders by June 9 noon. Further particulars may be obtained from the Company's office, 28, Rue de Châteaudun, Paris.

Digitized by Google

Glasgow.—The Corporation invite tenders for one economiser, with induced-draught fan, and condensing plant. Particulars may be obtained from Mr. W. A. Chamen, the engineer, 75, Waterloo-street, Glasgow. Tenders by June 7.

West Ham.—The Corporation invite tenders for the construction of about eight miles of route length of tramways. Specifications, etc., may be obtained from the offices of Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster. Tenders by June 10.

Brighton.—The Town Council invite tenders for the supply of points, crossings, tiebars, bolts, and other fittings. Specifications, etc., may be obtained on application at the office of Mr. Thos. B. Holliday, tramways engineer, Lewes-road, Brighton. Tenders by June 9.

Warrington. — The Coronation Committee invite tenders for illuminating the town hall and Bank-Park with electric light. Specifications, etc., can be obtained from the Borough Electrical Engineer, Electricity Works, Howley, Warrington. Tenders by June 2.

Launceston (Tasmania).—The Corporation invite tenders for polyphase generating, transmitting, and distributing plant and apparatus, transforming apparatus, reconstruction of existing plant, and enclosed arc lamps and accessories. Tenders by Sept. 15. See advertisement.

Dundee.—The Gas Commissioners invite tenders for the supply and delivery at the electric station of steel and iron steam-piping and fittings, cast-iron piping, and cast-iron manhole frames and covers. Specifications, etc., may be obtained from the Electrical Engineer. Tenders by June 3.

Stretford.—The District Council invite tenders for the following in connection with its scheme for supply of electrical energy: Steam-raising plant, comprising boilers, superheaters, economisers, etc.; generators, comprising engines, dynamos, condensers, pumps, etc.; and mains. Tenders by June 18. See advertisement.

Tonbridge (Kent).—The Urban District Council invite tenders for the fitting up of an electric light installation in their electricity works. Specification, etc., may be obtained at the offices of Mr. Robert Hammond, M.I.C.E., consulting engineer to the Council, 64, Victoria-street, Westminster, London, S.W. Tenders by June 9.

Astrachan.—Erection of electric generating station and installation of public and private lighting, commencing with 150 arc and 6,000 incandescent lamps. Manufacturers who will undertake to finish the work within two years can obtain particulars from the Municipality. Agents will not be able to tender. Tenders by June 7-20.

Stockton-on-Tees.—The Corporation invite tenders for the supply, delivery, and erection of one 300-kw. steam generator, two Lancashire type boilers, one switchboard panel and instruments, surface condenser and cooling plant, pipework and valves, extension feeders, and mechanical stokers, economiser, and feed pump. Tenders by June 10. See advertisement.

Bury.—The Tramways Committee invite tenders for the work required in the construction of the permanent way in several parts of the borough—viz.: Fairfield section, Bolton-road section, Heywood-street and Knowsley-street sections. Specifications, etc., can be obtained on application at the office of Mr. Arthur W. Bradley, borough engineer and surveyor. Tenders by June 24.

York.—The North-Eastern Railway Company invite tenders for the following articles in such quantities as they may require during six months ending Dec. 31, 1902, delivered (carriage paid) at the telegraph stores at York: telegraph apparatus and telegraph wire and line stores. Particulars may be obtained on application to Mr. Graves, Telegraph Department, York. Tenders by noon on June 9.

Worthing.—The Corporation invite tenders for the erection of a circular brick chimney shaft for their electric generating station, High-street, Worthing, 140ft. high from the ground level and 7ft. 6in. inside diameter at the top (the Corporation will construct the foundations and other brickwork to the ground level). Full particulars can be obtained on application to the Borough Surveyor, Municipal Offices, Liverpool-road, Worthing. Tenders by June 16.

Belfast.—The Harbour Commissioners invite tenders and designs for the decoration and illumination by electricity or otherwise of the harbour office and the south end of the Glasgow shed, Donegall Quay, in connection with the celebration of the coronation of King Edward VII. A detailed specification of the work proposed to be carried out must accompany each tender. Any further information required may be obtained from the harbour engineer, Mr. G. F. L. Giles. Tender by June 2.

RESULTS OF TENDERS.

Barnsley.—The Corporation have accepted the tender of the Electrical Power Storage Company for the supply of a storage battery.

Broughty Ferry.—The Town Council have placed the contract for the supply of a storage battery with the Electrical Power Storage Company, 4, Great Winchester-street, E.C.

Hamilton (Scotland).—The Town Council have accepted the tender of Edmundson and Co., London, at £32,302, for erecting new electricity generating station at Almeda Hill.

West Stanley (Durham).—The tender of W. B. Garrick and Co., Gateshead, Newcastle-on-Tyne, has been accepted for the electric lighting of the new Catholic church, West Stanley.

Swansea.—The Council have accepted the tender of Mr. D. Jenkins, Lower Oxford-street, at £996, for the foundation work in connection with the proposed extension to the station.

Limerick.—The contractors for the electric lighting of Limerick (the Allgemeine Elektricitats-Gesellschaft, of Berlin and London) have entrusted R. Carr and Co. with the order for the arc lamp columns required.

Mansfield.—The Town Council have accepted the tender of Crompton and Co., at £2,486, for (Section L) pipework, valves, and tanks.

Blackburn.—The Guardians have accepted the tender of G. H. Woods and Co., Northgate, Blackburn, at £169. 1s. 3d., for certain alterations and additions to the electrical fire-alarm installation at the workhouse.

Insulating Compound.—The National Telephone Company have accepted the tender of R. Carr and Co., Lime-street-square, London, E.C., for the supply of insulating compound for the six months ending Dec. 31, 1902.

Willesden.—The District Council have accepted the tender of the British Insulated Wire Company, Prescot, Lancs., for the supply and erection of arc lamp columns to be of the design and manufacture of R. Carr and Co., 6 and 8, Lime-street-square, London, E.C.

Bexleyheath (Kent).—The Electric Lighting and Traction Committee have accepted the following tenders: A. Penney and Co., 107, Fenchurch-street, E.C., tramway rails and fishplates; W. Scott and Co., Leeds Steelworks, Leeds, anchor plates; Dick, Kerr, and Co., 110, Cannon-street, E.C., bolts and nuts, tie-bars, etc.

West Ham.—The Corporation have received the following tenders for the construction of eight transformer chambers:

G. Wise, works manager, West Ham (accepted)	£675	0	0
Whitehead and Co., Portland-place, Clapham-road	710	0	0
Windsor and Co., 61, Strathblane-road, Clapham Junction	721	12	4
Foster Bros., 148, Birchanger-road, Norwood Junction	757	0	0
J. Jackson, Broadway, Plaistow	845	4	8
F. G. Minter, Ferry Works, Page-street, Westminster	907	0	0
Gregar and Son, Jupp-road, Stratford	984	0	0
C. Ford, 11, Nicoll-road, Harlesden, N.W.	995	0	0

Falkirk.—The following tenders have been accepted by the Electric Light Committee: Falkirk Iron Company, manhole covers, £124. 12s. 6d.; W. D. Hamilton, brickwork of pavement boxes; Buchanan and M'Donald, plaster work of pavement boxes and repair of pavement. Also tenders for work at the electric station buildings: O. M'Kearney, mason work; J. and P. Dewar, joiner work; J. Happer, slater work; R. Brown, plumber work; J. Marshall, painter work; Buchanan and M'Donald, plaster work; T. Laurie and Co., lightning conductor. No decision has yet been made regarding the cast-iron and steel work, for which the following firms tendered: Cameron and Co., J. Munday, P. B. Johnston, Watt and Co., W. Jones and Sons, W. Turner and Son, P. B. Smith and Co.

Fulham.—The following tenders have been received for the supply of a switchboard (Contract No. VI.):

Electrical Company, Limited	£316	15	0
Crompton and Co., Limited	338	0	0
Williamson and Joseph, Limited (accepted)	344	9	0
Geipel and Lange	373	14	0
Johnson and Phillips	377	0	0
Johnson and Phillips	379	10	0
Johnson and Phillips	385	0	0
General Electric Company (1900), Limited	401	0	0
General Electric Company (1900), Limited	424	0	0
Bertram Thomas	442	15	0
Siemens Bros. and Co., Limited	455	0	0
Siemens Bros. and Co., Limited	459	0	0
Kelvin and J. White, Limited	499	12	6
Electric Construction Company, Limited	511	0	0
Kelvin and J. White, Limited	525	0	0
R. Dawson and Co., Limited	529	0	0
Mechan and Sons	605	0	0

BUSINESS NOTES.

TRACTION.

Ipswich.—Tenders will very soon be invited for the construction of the proposed tramways in the town.

Chiswick.—The agreement between the District Council and the London United Tramways Company has been sealed.

Dornoch Light Railway.—This railway was inspected by Major Druitt, of the Board of Trade, yesterday, and will be opened for traffic on Monday.

Tipton.—The British Electric Traction Company have promised to consider the request of the District Council for a tramway from Ockerhill to Great Bridge.

Swansea.—A fractured trolley wire on the tramway system at this place fell to the ground on Monday afternoon, and a horse coming in contact with it was killed.

Ayr.—The municipal tramways have now been completed to Burns Monument, the total length being about 5¾ miles, of which over two miles through Ayr is double.

Mornington (N.Z.).—Negotiations are proceeding between the Town Council and the tramways company for the purchase of their undertaking by the Corporation.

Merthyr.—The Local Government Board have made an order extending the period for the completion of the Merthyr Electric Railway Company's lines from the 16th inst.

Dunedin (N.Z.).—The engineers' estimate for the construction of the Dunedin electric tram system is £160,891, the maximum being £170,000. Eighty-one pound rails are to be used.

Huddersfield.—A temporary stoppage of the electric cars occurred one day last week owing to the breaking of a guard wire, which fell on to the trolley wire and interrupted the electric current.

Digitized by Google

Northumberland.—The North-Eastern Railway Company have notified their intention of opposing the Northumberland Electric Tramways Bill in Committee of the House of Commons.

Chatham.—Several trial trips on the new electric tramways in the town have been made within the last two or three days, and it is expected that some of the routes will be opened for traffic on Tuesday next.

Speed of Motors.—The Cheshire Chamber of Agriculture at their last meeting discussed the speed of motorcars, and after a long debate a resolution was passed asking the authorities to fix a reasonable limit of speed.

Margate.—A fine of £5 and 9s. costs was imposed on the driver of an electric tramcar at Margate on Wednesday for driving down Forthill at the rate of 3¾ miles an hour, the Board of Trade limit being two miles an hour.

Appointment.—Mr. O. A. Pilcher, chief assistant electrical engineer to the Blackburn Corporation, has been appointed electrical engineer and tramways manager to the borough of Ilkeston. There were 35 applicants for the post.

Birkenhead.—Two of the municipal electric cars were in collision last week, but the incident was not attended by injury to any of the passengers. The impact, however, was so great as to smash in the front of one of the cars and break the lamp.

Bradford.—The work of converting the Otley-road section of the city tramways for electric traction has begun, and for the time being vehicular traffic over a portion of Otley-road will be diverted. A double set of rails will be put down, and from Harrogate-street to the end of Idle-road the road will be widened to the extent of 2½ yards.

Halifax.—Notwithstanding the cold wet weather experienced during the Whitsun holidays, the Corporation electric tramway receipts reached a higher total than last year. Five miles of new track have, however, been opened since last Whitsuntide. The total receipts for the four days from Saturday to Tuesday were £1,193, against £1,170 last year.

Rawmarsh.—The Urban District Council have sealed their agreement with the representatives of the company proposed to be incorporated by the Mexborough and Swinton Tramways Bill now pending in Parliament, under which the powers obtained by the Council under the Rawmarsh Urban District Tramways Act, 1900, have been transferred to the company.

Walthamstow.—A special meeting of the Urban District Council has decided to support the promoters of the City and North-East Suburban Electric Railway Bills in their endeavour to bring such Bills before the Joint Committee for further consideration. These proposals embrace a line from Cannon-street to Waltham Abbey, through Leyton and Walthamstow.

Lewisham.—With reference to the application to Parliament by the British Electric Traction Company for powers to construct tramways, to be known as the Croydon and district electric tramways, the Works Committee reported at the last Borough Council meeting that the portion of the line proposed to be constructed in the borough of Lewisham had been struck out of the Bill.

Doncaster.—The Board of Trade inspection of the completed sections of the new municipal tramways took place on Tuesday. The overhead trolley system has been adopted, and the estimated total cost of the undertaking is put at £77,500. The lines, so far as Balby and Hexthorpe and Frenchgate are concerned, will, it is expected, be ready for public traffic in about a week's time.

Gloucester.—The City Council have confirmed their resolution to purchase the tramways and lay down a system of light railways in the borough. The Gloucestershire County Council have also a light railway scheme on hand, they having given official notice of intention to apply for powers to construct two railways in Wotton St. Mary (Without), Barnwood, Hucclecote, and Brockworth.

Wycombe—This place has decided that it is not yet ripe for electric tramways. The whole question was discussed at great length at the last meeting of the Town Council, when a large majority passed a resolution to postpone the subject until 1904, the date when the first option for purchase of the electric light undertaking comes into effect. It is noteworthy that only five voted in favour of tramways.

Tramway Extensions.—The London United Tramways Company have given official notice at Slough that they intend to apply to the Light Railway Commissioners for power to extend their system of electric tramways to Colnbrook, Slough, Taplow, and Maidenhead, with branches connecting the Great Bath-road with the Great Western Railway at Langley and the South-Western Railway at Datchet-on-Thames.

Heywood.—The examiners of Standing Orders in the House of Lords have had before them a Bill concerning a number of tramway orders granted to local authorities, including one granted to the Heywood Corporation authorising the construction of about five miles of tramway lines within the borough. The Standing Orders of the House were found to have been complied with, and the Bill was ordered to be reported for second reading.

Oldham.—The electrification of the whole of the tramways in the borough has now practically been accomplished. The first sections of the reconstructed lines running through the town were formally opened last week. When the whole scheme is completed there will be a total length of tramway route of 21 miles, the aggregate length of single track being 30 miles. The estimate presented at the Board of Trade enquiry amounted to £427,034.

South Lancashire Tramways.—Good progress is being made by the contractors for considerable lengths of the South Lancashire tramways. The Tyldesley lines have been completed, and at Leigh the track has been laid from the Lowton boundary to near the junction of the borough with Atherton, and will shortly join up with the length from Hulton. Considerable headway has also been made with the erection of a large generating station at Howe Bridge.

Armley.—A somewhat singular tramcar accident at Armley, one of the suburbs of Leeds, was on Monday the subject of an official enquiry. An electric car laden with passengers was on the previous afternoon proceeding from Stanningley to Leeds when, on taking a curve near Castleton Bridge, it travelled 70ft. on the stone setts, rushed over the causeway, crashed into the bridge, and 17 passengers were injured or shaken. It appears that the brakes did not act, and they are to be subjected to exhaustive tests.

Middlesex.—The County Council have resolved to apply to the Light Railways Commissioners for authority to construct certain further light railways within the county. The county engineer's approximate estimate of the cost of the new railways included in the recommendations is £654,612, which covers the purchase of lands, widenings, and construction of the tracks, and the cost of the purchase of additional land for widenings and works incidental thereto, £228,772—making a total of £883,384.

Wolverhampton.—Another accident, arising, it is said, out of the use of the Lorain surface-contact system of traction, is reported from here. On Monday a horse was drawing a cart along Bilston-street when it was supposed to have stepped on to a live contact box, as it was immediately brought to the ground. The carter in charge, who was walking alongside, at once went to the assistance of the animal, and he also received a shock. Neither the man nor the horse, however, suffered anything but a temporary sensation.

Rochdale.—As announced in our last issue, the Bury-road section of the Corporation tramways was opened for traffic on the 22nd inst. When completed, the system will connect up Rochdale with Summit (beyond Littleborough), Heywood, Norden, Royton, Healey, etc. The section open is only about a mile long, and extends from the southerly end of the Esplanade (near the town hall) to a point where the borough of Rochdale joins the urban district of Norden, on the Bury old road. The next section to be completed will be the line to Norden.

Northfleet.—At their last meeting the District Council decided to adhere to the conditions which they have already attached to their permission to the tramway company to lay their cables underneath the footpaths. Subject to the execution of such agreement, the company's amended plans showing the proposed route of their electric cables have been approved. An amended plan showing the proposed sites for the feeder pillars has also been approved, subject to the exact position of every pillar being settled by the surveyor prior to the ground being disturbed for its erection.

Dudley.—On Saturday one of the guard wires connected with the tramway in High-street suddenly snapped and fell across the trolley wire, a considerable length of the broken strand being extended along the street. The contact with the trolley wire caused the broken guard wire to become "alive," and wherever it touched the rails sparks were emitted. Ladders, gloves, pliers, etc., were at once obtained from the police station, but before the wire could be removed there had been a complete block in the tram service, and a partial block in the street traffic, lasting about three-quarters of an hour.

Asylum Light Railway.—We understand that a light railway is to be put down between Hellingley Station and the East Sussex County Asylum, a distance of 1,900 yards, on the overhead trolley system. Power for working the line will be obtained from the generating plant which is being laid down at the asylum. A locomotive capable of hauling two trucks containing about 10 tons each at six miles per hour on an up grade of 1 in 50 is to be supplied, also a tramcar for passenger service capable of running at a speed of eight miles an hour. A suitable main traction switchboard is also included in the contract.

Greenock.—On an application to the general licensing court for the renewal of tramcar licenses last week, the Provost, referring to the height of car steps, reminded Mr. Braidwood that 12 months ago the magistrates recommended that these steps should be lowered, and they regretted that the company had not seen their way to do so. Mr. Braidwood, in support of the application, said that the steps had in the course of usage gone down about 1½in. Further he could not promise, simply because the engineers could not see how it could be done. In granting renewals, the Provost said that the magistrates would make personal enquiry into the subject.

Bournemouth.—The Town Council have received a memorial from tradesmen residing in the central ward calling attention to the serious inconvenience and loss of business that must necessarily arise through the disturbed state of the road for the laying of tram railways in the main business thoroughfares of this town, and suggest that this can be diminished by the contractors being directed to work day and night. A letter was read at the last meeting of the Town Council from the Light Railway Commissioners stating that a draft of the provisional order of the Poole and district light railway extension would be forwarded for the observations of the Corporation.

Heath.—At the last meeting of the District Council letters were read from the County Council, Wolverhampton Town Council, and the British Electric Traction Company with reference to the delay in laying the tramways along the Willenhall-road to connect the district with the borough. The County Council stated that for some reason the British Electric Company did not at present propose to complete the tramways, while the Town Council said the matter was before their committee, and the tramway company could not at present give any definite information. This Council were very anxious for the tramway to be finished through their district to the borough boundary.

Carshalton.—A scheme is being promoted by the British Electric Traction Company to run a tramway through this place to link Sutton with Croydon, and the inhabitants are very much opposed to the

Digitized by Google

proposal. To run an electric tramway through the quaint old High-street on the overhead trolley system would, it is said, destroy its primitive character, as many of the old buildings would have to be removed to give sufficient width. The only alternative route is by the Wandel, and the church where Anne Boleyn's well is sacredly preserved. The adoption of this route would be scarcely less objectionable than the other, and the Carshaltonians protest against either being adopted.

Hastings.—A special meeting of the Town Council has, after a lengthy discussion, adopted a resolution that the Council accede to the application for their consent to the Hastings Tramways Bill, 1902, on condition that the promoters give an undertaking to insert certain clauses and provisions therein, one of which provides that the company shall not, without the consent of the Corporation, open the proposed extension tramway between the west end of Grosvenor-crescent and the Albert Memorial, along the sea-front, and through Robertson-street, for traffic until the line through Clive-vale to the top of High-street, already authorised, shall have been completed and opened for traffic.

Pontypridd.—At a meeting of the Pontypridd District Council on Tuesday it was reported that a joint meeting of the Pontypridd and Rhondda Councils had been held with regard to the proposed purchase of the British Electric Traction Company's tramway between Pontypridd and Porth. The meeting had been convened to consider the advisability of the Councils jointly entering into negotiations with the company with the object of immediately purchasing their undertaking instead of doing so next year, having regard to the present stoppage of the tramway. It was decided to ask the company to name a sum for which they would be prepared to sell. The clerk was instructed to take the necessary steps to obtain the sanction of the Local Government Board to borrow money required in connection with the tramways and electric lighting schemes.

Newcastle.—It is expected that during June the double tramway over Byker Bridge will be opened for traffic. The tramway along Clayton-street is now nearly ready for opening, and the Board of Trade inspectors have been asked to examine the lines. Lieut.-Colonel Von Donop has already made an official inspection of the Dunston tramways extension. This extension, which is about three-quarters of a mile in length, commences at Pine-street, Teams, and terminates at the railway bridge, near the Cross Keys Inn, Dunston. Colonel Von Donop expressed his satisfaction with the line, and will grant the customary order in due course. The Tramways Committee have decided to provide the manager with a motorcar, to be kept in readiness at the power station, to reach any given point requiring his attention with the least possible delay.

Liverpool Overhead Railway.—Another outbreak of fire at the Dingle Station of the Liverpool Overhead Electric Railway occurred on Monday night, but, fortunately, it was unattended by any serious result. A train, consisting of three carriages, was standing at the platform when a flame was seen to issue from the motor box, and the woodwork around caught fire. An alarm was given, and the station officials were quickly on the scene with a hose and hydrants, the flames being extinguished before much damage was done. The official explanation of the fire as given by Mr. S. B. Cottrell, the general manager of the railway, is as follows: one of the magnets fused; the electric current was at once cut off, and the ignition of the cable extinguished by the station staff with little or no damage. The whole occurrence only occupied a very few minutes, and caused practically no dislocation of the service.

Burton and Ashby Light Railway.—It is stated that the Midland Railway Company, who successfully opposed the scheme for the Ashby, Swadlincote, and Burton light railway, when the matter came before the Commissioners at Swadlincote a few months ago, are about to apply for an order authorising them to construct the Burton and Ashby light railway. The scheme is practically on the lines of that which was originally promoted by private gentlemen in South Derbyshire, but which fell through owing to the company's opposition. The railway, which will have a gauge of 3ft. 6in., is to begin where the Burton Corporation tramway system ceases at the east end of the Trent Bridge, and will terminate in the company's station yard at Ashby. Church Gresley and Castle Gresley will be served by a loop-line. Electrical traction will be used, and for this purpose a generating station is to be erected on ground adjoining the company's branch railway at Swadlincote.

Colombo Electric Tramways.—The Anglo-American Debenture Corporation, Limited, having purchased £120,000 5 per cent. first mortgage debenture stock of the Colombo Electric Tramways and Lighting Company, Limited, are offering for sale, on their own behalf, £100,000 of that stock at par. The debenture stock, in accordance with the trust deed, will be secured by a first mortgage upon the central station, car-houses, works, stores, and offices of the tramways company at Colombo, and by a floating charge on the residue of the company's undertaking in favour of the trustees for the debenture stockholders. The Colombo tramways consist of 14 miles of single line, and were constructed in 1898 on the overhead system under an exclusive concession granted by the Municipal Council of Colombo. The net profits for the three years ending Dec. 31, 1901, after paying all renewals and repairs, were: 1899, £10,706. 17s.; 1900, £12,808. 10s. 4d.; 1901, £12,230. 6s. 2d.

Tramways in London.—In a letter on the subject of tramway extension in London, Mr. R. M. Beachcroft, L.C.C., acting on a proposal made by Sir J. Dickson-Poynder, suggests that a tribunal should be constituted, somewhat on the lines of the Light Railway Commission, to hear and decide all matters affecting the promotion of schemes for locomotion, whether under or above ground, in our cities, and to control and supervise the undertakings when sanctioned. "Among the subsidiary matters which such a tribunal might deal with may be mentioned," he adds, "the fixing of the quota of contribution towards the cost of street widenings required primarily for tramway purposes and the settlement of terms for interchange of traffic and running powers between different tramway authorities, as, for example, the London County Council and the tramway authorities outside London. The pressing needs of population in London demand the expansion and quickening of all means of locomotion; and if Acts of Parliament and Standing Orders, reasonable as they may have been so comparatively recent as 1870, are now found to be antiquated, fresh machinery should be devised to suit the wants of the day."

Cardiff.—The Corporation have received a sum of £30,000 on account of the new tramway loan. The Tramways Committee have adopted the suggestion of a sub-committee that 2½ per cent. of the gross revenue be set aside for the formation of a fund to indemnify anyone injured by accident on the cars, instead of insuring through a company. It is estimated that the sum available for this purpose at the end of the year of work would be £1,600. Mr. Ellis, the electrical engineer, has reported with regard to Sunday work that, in reply to printed circulars issued to the electric car employés, 161 had expressed their willingness to undertake it and 12 objected on conscientious grounds. The electrical engineer, through the columns of the daily Press, has issued a warning to cyclists calling attention generally to the great risks they run in continually persisting in riding in front of the electric cars. It is quite a common occurrence, he says, for cyclists to persist in riding immediately in front of the cars—which, as will be recognised, travel at a much greater speed than the horse cars—and trying to see how close they can keep ahead of the same. In doing this they do not recognise the risks they run, especially on wet days, by the wheels of their bicycles skidding and throwing them to the ground, and should this happen it would be impossible for them to save themselves or for the drivers to pull up a car in sufficient time to avoid accident.

Aberdeen.—Mr. M'Elroy, of the firm of Messrs. M'Elroy and Grunow, Bridgeport, Conn., U.S.A., is at present carrying out experiments here in connection with the twin-rail system of electric traction. The firm received permission from the Town Council to lay down rails for the working of the new system from the foot of Constitution-street, across the Queen's Links, to the Corporation bathing station, but when the work came to be tested early last summer, it was found that the system was not working so satisfactorily as was anticipated. As the bathing season was coming on, and it was necessary that the electric cars should be running to the beach, the Town Council agreed to complete the section across the links on the overhead system of contact, but granted an extension of time to the firm to carry out their experiments at some future time if they deemed that desirable. It is in accordance with this permission that Mr. M'Elroy and an engineer are now carrying out the work. A car is being fitted up in the Corporation tramway depôt at Woodside to be run on the new system, which is said to have been greatly improved since last year, now resembling more the stud or Lorain system which is at work at Wolverhampton. At a meeting of the Tramways Committee on Monday, the question of running the tramcars on Sundays was under consideration. The treasurer intimated his intention of moving in this direction at the ensuing meeting of the Town Council.

Preston.—On Tuesday the Earl of Jersey, Colonel Boughey, C.S.I., and Mr. H. A. Steward, Light Railway Commissioners, heard an application by the promoters of the Preston and Lytham light railway for an order empowering them to construct a light railway by way of Freckleton, Worton, and Lytham. A somewhat similar application made in September last year was refused. A good deal of discussion took place as to the financial position of the promoters, and Mr. H. J. Lawson, consulting engineer to the Electric Tramways Maintenance and Construction Company, gave evidence on this point. Mr. Page, K.C., who appeared to oppose the scheme on behalf of the Lancashire and Yorkshire and London and North-Western Railway Companies, submitted that the proposal came within Section 9 of the Light Railways Act, or the competitive clause, and said the effect in that direction on the Lancashire and Yorkshire Railway Company would be serious. Mr. Warton, general goods manager of the Lancashire and Yorkshire Railway Company, said the competition of the proposed line would to some extent affect the dividends of that company. The Earl of Jersey, after consideration with his colleagues, said that, looking at the large expenditure which it was proposed to employ upon the line, and seeing the large population at both ends, which must come within the consideration of the promoters, the Commissioners were limited to apply the Light Railways Act, and they were of opinion that this line did come within the purview of Clause 9, the competitive clause, and upon that ground alone they felt it would be no use their attempting to recommend an order.

Christchurch (N.Z.).—The Borough Council of Christchurch, New Zealand have received an offer of two tramway schemes from the British Electric Traction Company through the local agent of the company, Mr. P. M. Hansen. In the first the company would form a subsidiary company in London with a nominal capital of £250,000, having a local board of three ratepayers to be appointed jointly by the local bodies interested. The company to have a 30 years' concession, paying £200 a year to the Christchurch City Council by way of repairs to the street and a further £400 a year to be divided among the other local bodies. Ten per cent. of the actual net profits would be divisible between the Corporation and the other local bodies interested. At the end of 10 years the boroughs interested to have the right to purchase the tramway concession at valuation plus 10 per cent. in lieu of commission, for conversion, construction, equipment, and supervision. A similar offer is made at the end of 20 years, except that commission is reduced to 5 per cent., and a similar offer is made at the end of the term upon a basis of no commission being payable. The other proposal provides for municipal ownership, the City Council and local bodies providing the necessary capital and giving the British Electric Traction Company a lease for a term of 21 years at least. The local bodies interested are

Digitized by Google

to raise by loan the necessary money to take over the tramway lines from the existing company, the British Company guaranteeing the payment of the interest on such loan during their lease with a sinking fund to extinguish loan at its termination. The company would receive as remuneration for preparation of plans and specifications, for supervision and construction and equipment of the trams a commission of 10 per cent. (per annum?) on the actual cost of the whole of the works connected with the conversion and construction of the lines. The company would also pay £50 a year for each mile of line in lieu of keeping it in repair. In the event of either of these two offers being accepted Mr. Hansen would examine and report upon the Waimakariri water-power scheme.

Leeds.—On Monday the Corporation Tramways Committee approved accounts which reveal a profit (after payment of interest and sinking fund charges) of £48,241. 5s. 11d. The accounts showed that while expenditure has increased by £21,747, the revenue has increased by £41,094. The total revenue amounts to £224,294, of which sum £221,308 comes under the head of car receipts, as much as £195,882 being in respect of electric traction. Running expenses and administrative charges furnish a total of £143,150, leaving a gross profit of £81,144. From the latter figure interest has to be deducted, amounting to £19,829; thus there is a net profit of £61,314. And when sinking fund charges, amounting to £13,073, are deducted, there is a clear surplus of £48,241, an increase of £17,183. 3s. 5d. on the previous year's profit, and of £42,000 on the balance of 1899-1900. In the course of the year the cars have run 4,726,043 miles, or 965,758 miles more than in the preceding 12 months, and have carried 48,273,300 passengers, an increase of 8,938,825. Where the electric cars ran 2½ million miles in 1900-1901, they have covered four million miles in the financial year just closed. The earnings per electric car mile have dropped 1½d., and the expenses (exclusive of interest and sinking fund charges) have risen from 6·49d. to 6·63d. Yet an addition of more than £62,000 has been made to the total electric earnings of 1900-1, which is attributed to the improved quicker and extended service that has been put on in the past 12 months. One or two other points are noteworthy, the reduced cost of generating electricity especially so. While in 1900-1 this item was at the rate of ·60d. per mile, it amounted in 1901-2 to only ·39d. per mile, owing partly to the purchase of coal on more favourable terms, but mainly to the fact that an increased output of electricity has kept the power station employed in a uniform degree and on a more economical basis. In almost every branch of expenditure except that of wages considerable economies have been effected. The year's wage bill amounts to over £70,000, which is nearly 50 per cent. of the total outlay of £143,150, and this is exclusive of the wages paid indirectly in the form of repairs and renewals. The capital expenditure on the Leeds tramway system has now reached £895,000.

LIGHTING AND GENERAL.

Ipswich.—Amended plans for the electric lighting installation have been approved.

New Zealand.—The town of Gore is about to expend £5,000 on electric lighting plant.

Barnes.—The Urban District Council are obtaining a loan of £3,000 for electric street-lighting.

Eton.—The District Council have given their formal sanction to the electric lighting scheme at Datchet.

Hampstead.—Mains for the supply of electric current to private consumers are to be laid in portions of Cressy and Redington roads.

Buxton.—The Electricity Committee have agreed to allow a discount of 10 per cent. for prompt payment on current supplied from Lady Day last.

Berwick.—The Sanitary Authority are urging the company who had arranged to put the electric light into Berwick, to take steps to carry out their promises.

Brownhills.—The Urban District Council have granted permission to the Walsall Wood Colliery Company to carry an electric cable from the colliery to the institute at a height of 24ft. above the road.

Agency.—The Klein Engineering Company, Limited, 94, Market-street, Manchester, have appointed Messrs. Harvey and Co., of 25, Victoria-street, Westminster, S.W., definitely as their London representatives.

Hythe.—The Town Council at their last meeting decided to ask the Folkestone Electricity Supply Company whether they will undertake to give the value of their provisional order before the expiration of next month (June).

Stock Exchange.—The Stock Exchange Committee have appointed June 11 a special settling day for Marconi's Wireless Telegraph Company's further issue of 7,264 shares of £1 each, fully paid, Nos. 149,820 to 157,083.

Electrocuting Rats.—It is reported that in order to assist in ridding Sydney, New South Wales, of plague-stricken rats, a local scientist has invented a trap in which as soon as the animal touches the bait it is electrocuted.

Colchester.—The electric service cable broke in St. John's-street, Colchester, on Monday, and, owing to the sewer recently put in, electrified the road for some yards. The electricity affected passers-by, but there was no personal accident.

Londonderry.—We understand that in consequence of a private company having the intention of applying for a lighting order the Corporation have decided to carry out the scheme proposed by Sir W. Preece, which is estimated at £35,000.

Ormskirk.—The Urban District Council have decided to circularise the ratepayers over £10 ratable value as to whether they would take the electric light. As an installation would cost £15,000, the Council propose to take current from the Southport Corporation at 6d. per unit.

Huddersfield.—Sanction has been received from the Local Government Board to the borrowing of £99,483 for the purposes of electric lighting. Electricity and gas for outside illuminations and decorations during the Coronation festivities on three days are to be supplied free to ratepayers.

Personal.—Mr. William M. Furniss, formerly with Messrs. Handley and Shanks, of Birmingham, has been appointed the representative of the Electric Construction Company, Limited, in South Wales and district. Mr. Furniss's address, *pro tem.*, will be 70, Beauchamp-street, River Side, Cardiff.

Stafford.—From the Town Council's budget it appears that there is in the electricity department a deficiency in the accounts of £1,100, but this is not so great as was expected. One of the causes for the large amount being thrown on the rates is the fact that the department had no reserve fund and no depreciation fund.

Catalogues Received.—The Electrical Company, Limited, of 122, Charing Cross-road, W.C., have just issued their price list No. 4, which deals with generators for single and multiphase alternate-current working. It will be remembered that this firm is the agent for the Allgemeine Elektricitäts-Gesellschaft, of Berlin.

Scarborough.—The town clerk has been instructed to apply to the Postmaster-General, under the Telegraph Act, 1899, for a license to construct and work a system of municipal telephones in the telephone area of Scarborough up to the year 1920, and if such license is obtained tenders for carrying out the work are to be advertised for.

Faversham.—Estimates of the cost of establishing the supply of electric light were before the General Purposes Committee at their meeting on Tuesday. The total estimated cost, including site, is £24,109. After discussion and explanation by the engineer, Mr. H. Talbot, it was decided to apply for sanction to borrow the sum named.

Dumfries.—Prof. Capper visited Dumfries on Monday with a view to advising the Town Council on the subject of a proposed electric light installation. He was also taken over the ground between Dumfries and the seaside village of Glencaple, it having been suggested that an electric car line might be laid along the five miles of road.

Explosion.—An explosion of gas which had accumulated in one of the electric cable manholes in Union-street, Aberdeen, occurred on Saturday. The concrete slab covering the aperture was blown into the air, and a volume of smoke and flame issued from the hole. Though a good many pedestrians were on the pavement at the time, no one was hurt.

Wycombe.—Mr. Cecil F. Love, of the Halifax Corporation electricity works, has been appointed to fill the post of chief assistant engineer at the Wycombe (Borough) Electric Light and Power Company, Limited, works. There were 84 applicants. Mr. Love gained his experience at the electricity works at Reading, Shoreditch, West Ham, and Halifax.

Bath.—The Electric Light Committee's accounts for the last year show a profit of £850. The advance in the charge for the public arc lamps to £31 is responsible for this; the charge for the public lamps has now been reduced by £7 per lamp, and this will reduce the receipts by £1,200. The Mayor has been elected chairman of the Joint Committee.

Roentgen Rays – Mr. T. R. Ferens, J.P., has presented to the medical staff at the Hull Royal Infirmary a valuable apparatus for the light treatment, ultra-violet rays, which is being worked in conjunction with the X-rays. The apparatus will be used in the treatment of certain skin diseases, and is considered to be of invaluable assistance to the medical profession.

Belfast.—Messrs. Harland and Wolff, Limited, are to be supplied with current for their pumping station at the Alexandra Graving Dock at the ordinary price charged to other customers, and a guarantee to take a certain quantity of current for five years will be asked for. The firm's application for 200 lamps for illuminating purposes has been referred to the engineer.

Aberdeen.—At the last meeting of the Municipal Telephone Committee a report by Mr. Bennett recommending that the municipal system should be adopted in Aberdeen was submitted. It was stated that the proposed system involved an expenditure of £58,000, and it was proposed that the committee should inspect the Glasgow system, but no definite action was taken.

Ark Lamps.—A further number of "Ark" lamps have just been supplied by Messrs. Johnson and Phillips for the lighting of the Boer prisoners' camps, as a result of the previous lamps giving satisfaction. Quick delivery was again a condition of importance, and this, we are informed, Messrs. Johnson and Phillips were able to comply with, owing to the large stock of all sizes kept by them.

Carlisle.—The Electricity Committee have agreed to supply the Caledonian Railway Company with 15,000 units per annum, for the purpose of lighting the company's yard, at the price of 2½d. per Board of Trade unit. It has also been agreed to extend, at a cost of £200, the electric cable along the streets forming the Botchergate-arcade which the Carlisle Estate Company propose to erect.

Bridlington.—The Town Council propose to ask Mr. Medhurst to prepare, in conjunction with the borough surveyor, plans and specifications and estimates, with a view to tenders being obtained for carrying out the works authorised by the electric lighting order of two years ago. The Council will possibly also be induced to consider the construction of electric trams to be run by the same plant.

Londonderry.—The Corporation have already adopted the report of Sir William Preece, and have decided to proceed with the carrying out of the scheme advised by him for the supply of electric light and power

Digitized by Google

to the whole city, and to apply for a loan of £35,000. At their last meeting they decided that the specification of Mr. Macrory, the electrical engineer, be printed and circulated, and that the meeting be adjourned for a month.

Edinburgh.—The last report of the Electric Lighting Committee states that the number of lamps applied for from May 1 to 15 were: lighting, 5,061 8-c.p. lamps; motors, 1,416 8-c.p. lamps; heating, 560 8-c.p. lamps—total, 7,037 8-c.p. lamps. The following shows the gradual increase of the number of 8-c.p. lamps connected since 1897: 1897-1898, 58,949; 1898-1899, 67,821; 1899-1900, 69,848; 1900-1901, 81,995; 1901-1902, 85,545.

New Addresses.—Messrs. Heathman and Co., the ladder makers, inform us they have opened a South Kensington depôt at 351, Fulham-road, where they will keep a stock of ladders, step-trestles, and scaffolds for the use of electricians in the West-end of London.—The registered address and general offices of the Charing Cross and Strand Electricity Supply Corporation, Limited, are to be removed to 60, St. Martin's-lane, W.C., from the 31st inst.

The General Electric Company's Catalogue.—We are asked to correct a statement in our notice of this large catalogue, which appeared in last week's issue, to the effect that it was the third edition. The company in question informs us that the present is the sixth edition, the first having been issued in 1893. We need hardly say that each succeeding issue has contained an increased number of pages and more information than the preceding one.

Presentation.—Mr. J. W. Kempster, on leaving Messrs. W. H. Allen, Son, and Co., Limited, of the Queen's Engineering Works, Bedford, where he has been chief electrician for 14 years, to take up a similar position with Messrs. Harland and Wolff, of Belfast, has been presented by the members of the firm with a collection of Sheffield plate over 100 years old, while from the staff he received two etchings by Rowe. During his connection with Messrs. Allen, Son, and Co. Mr. Kempster has had 280 vessels in his hands for installing electric light, including the "Oceanic" and the "Celtic."

Liverpool.—A discussion took place at the last meeting of the Mersey Docks and Harbour Board on a proposal of the Marine Committee to enter into an arrangement with the postal authorities for the extension of the telegraph system at the docks and as far as the South Stack Lighthouse. A member said he thought the Board had established as far as was necessary the system of telephones, but the Chairman said their engineer had reported that to give orders by telephone was a very unsafe and undesirable method, and he strongly recommended telegraphs. After further discussion, the proposal was referred back.

Sunderland.—The Electricity and Lighting Committee are considering a scheme for the supply of current for motor purposes to various shipyards, large engineering works, and graving docks in the port and river. It is proposed to supply electrical energy at such a price as will satisfy the consumers, and in 12 months this, it is estimated, will double the output of the electricity works, which is now about 2,250,000 units per annum. The net profit upon last year's working of the electricity generating stations was £1,938, and the aggregate profits of £4,015 for the last four years have enabled the committee to repay the money taken from the rates in the preceding three years, leaving a credit balance of £1,346.

Battersea.—From the report of the Lighting Committee we note that Mr. S. Hale has been appointed chairman of the committee for the ensuing three months, and that Mr. A. Whitie, who has been acting as shift engineer at the central electric generating station during the past six months, has been appointed on the staff as shift engineer. Electric mains are to be extended from Church-road to the premises of the Bridge Cycle Company in Battersea Bridge-road, at an estimated cost of £55. 2s. The Council have refused an application for the use of a portion of the central electric generating station, etc., in connection with the King's dinner and Coronation celebrations, deeming it inadvisable having regard to the close proximity of machinery, etc.

Northern Counties Electricity Supply Co.—Mr. John D. Milburn, presiding at the first annual meeting of the Company in Newcastle on Tuesday, spoke favourably of their Blyth works, which would gradually extend, and the same, he said, applied to Spennymoor. Their early success at these two places had been largely due to the adoption of the penny-in-the-slot meter, and free wiring, which enabled small consumers to take advantage of the electric light. They had secured the whole of the public street-lighting in Hebburn and Felling, and they had obtained, or expected shortly to obtain, powers for Consett, Shotley Bridge, Annfield Plain, Stanley, and Leadgate, or a population of 100,000, for which they were waiting the erection of a large power station.

Maidenhead.—The Corporation are busy with the installation of electric lighting plant. Messrs. Burstall and Monkhouse are the consulting engineers and Mr. C. O. Milton the resident engineer. The plant will consist of two Babcock and Wilcox water-tube boilers of 1,619 square feet per boiler, and three Clayton Engineering and Electrical Construction Company's engines of 95 i.h.p. and 500 revolutions, each direct coupled to three dynamos, by the same makers, of a total capacity of 180 kw., and two 128-cell accumulator batteries. The three-wire system has been adopted, and the street-lighting will comprise 35 British Schuckert arc lamps of 10 amperes and 70 16-c.p. incandescent lamps. Private consumers are to be charged 6d. per unit for lighting and 3d. for motors.

Uxbridge.—The Uxbridge and District Electric Supply Company's electric lighting station is to be opened in June. Messrs. Kincaid, Waller, and Manville are the consulting engineers. A capital of £20,000 is authorised. The plant will consist of two semi-marine Davey-Paxman boilers of 160lb. pressure and 1,780 square feet internal surface, and two 150-h.p. and one 50-h.p. Belliss and Morcom engines of 500 and 600 revolutions respectively, direct coupled to four General Electric Company's dynamos with a total capacity of 180 kw., and three multipolar 7·25-kw. tail-shaft-driven exciters. There is no street-lighting at present. In the town 7d. and 3d. per unit will be charged for lighting and outside a flat rate of 8d. Mr. A. Randall Bell, A.M.I.E.E., is the resident engineer.

Oban.—The Corporation's electric lighting station is progressing. Messrs. Burstall and Monkhouse are the consulting engineers, and Mr. M. P. Plunkett is the resident engineer. A loan of £20,000 is authorised. The plant will consist of two Babcock and Wilcox water-tube boilers of 2,010 square feet super each, and three James Howden and Co.'s 95-h.p. engines, direct coupled to three International Electrical Engineering Company's shunt-wound dynamos, of a total capacity of 180 kw., and two 128-cell accumulator batteries. The three-wire system has been adopted, and the street-lighting will comprise 30 Oliver 10-ampere arcs and 60 16-c.p. incandescent lamps. Private consumers are to be charged 6d. per unit for lighting and 3d. for motors. The yearly charge for street-lighting will equal about 2d. per unit.

Telephone Call Offices.—A correspondent recently suggested to the Postmaster-General that the public should be allowed to hand to attendants at telephone call offices written messages to be telephoned when the lines became free, so that the senders might be saved the necessity of waiting for indefinite periods at the call offices. The Postmaster-General has now replied regretting he is unable to adopt the suggestion, because "owing to the uncertainty of being able to communicate with any particular subscriber in a distant town, and also to the fact that no guarantee could be given to senders as to the time or accuracy of transmission, the proposed arrangement would probably offer no advantage to the public over the transmission of ordinary telegrams, while at the same time it would give rise to difficulties in the internal arrangements of the Post Office."

Blaenau Festiniog.—Lord Newborough on the 22nd inst. formally opened the electric supply of the quarry town of Blaenau Festiniog provided by the Yale Electric Power Company, which was formed two years ago for the purpose of developing to some extent the immense amount of water power running to waste in the district, and thereby cheapening the production of slate by supplying power to the quarries during the ordinary working hours for hauling, pumping, mill-driving, and like purposes; also for lighting the streets and for private consumers. The company are enabled to supply electric light to the latter at 4d. per unit, and to supply power to the quarry companies at 1d. per unit. The company have entered into an agreement with the District Council to light the streets and supply private consumers at 4d. per unit for 15 years. A banquet was held at night in further celebration, when Lord Newborough presided.

Morecambe.—The accounts of the electricity department for the last 12 months show a fairly successful year. At the commencement of the year the committee estimated they would require a 6d. rate, which was equivalent to £2,175. They have actually spent £1,632, leaving a balance to the good of £543. 18s. 3d. The revenue increased by £177. 1s., and the gross profit by £120. 17s. 5d. The amount paid in principal and interest during the year was £3,355. 14s. 7d. as compared with £2,281. 2s. 9d., or an excess of £1,075. 11s. 10d. over last year. Current is charged at 5d. (and gas at 3s. 9d.), and it is anticipated that by the end of another year a 4½d. or 5d. rate only will be required, notwithstanding the increased payment to be made on account of capital. We note that in response to a customer who did not wish to pay the meter deposit a shilling prepayment meter has been procured, showing a businesslike desire on the part of the committee to meet the requirements of their customers.

Coronation.—The directors of the Electrical Power Storage Company, Limited, have decided, in commemoration of the Coronation of King Edward VII., to pay their workmen a full day's pay for the Coronation Day holiday, and to illuminate their premises at 4, Great Winchester-street. The construction has begun in Whitehall of Canada's wheat arch for the Coronation, about 150 yards south of the Horse Guards. It will be lighted with electricity after dark during the Coronation week, and will form one of the most attractive decorations in London. Stoke Newington Borough Council will expend £330 in connection with the Coronation. A large scheme for decorating and illuminating Marlborough House is in the hands of Messrs. J. Defries and Sons, Limited, of Houndsditch, the firm who have the contract for the Temple Bar and Ludgate-circus. Messrs. James Pain and Son, of Walworth-road, will ornament the Mansion House, the Royal Exchange, the Monument, and the Peel statue in Cheapside, while Messrs. Piggott Bros. and Co., of Bishopsgate-street Without, will deal with London Bridge. The Eastbourne Town Hall is to be illuminated with 700 electric lamps.

New Issue.—The British Insulated Wire Company, Limited, announces the issue, at par, of £250,000 4½ per cent. first mortgage debenture stock, being the balance of an issue of £500,000. The company has an authorised share capital of £1,000,000, half in 6 per cent. cumulative preference shares and half in ordinary shares of £5 each, all of which have been issued and fully paid. The company has, with a view to a complete amalgamation of the two businesses, acquired the assets and undertaking of the Telegraph Manufacturing Company, Limited, Helsby, near Warrington, and the constantly growing business of the two companies necessitates the provision of further capital. With the view of providing such capital, the company is making the present issue of £250,000 first mortgage debenture stock. The prospectus states that the whole of the stock now being issued has been underwritten. The Charing Cross and Strand Electricity Supply Corporation, Limited, offers for subscription, at par, 40,000 "City Undertaking" 4½ per cent. cumulative preference shares of £5 each. The dividend on these preference shares will be payable exclusively out of the net profits of the corporation's City undertaking and of any present or future investments by the corporation in the share capital of the Charing Cross and City Electric Company, Limited.

Digitized by Google

Horsham.—The Urban District Council have adopted a report of the Electric Lighting Committee, in which they state that they had considered the advisability of extending the supply of electric current in various parts of the district, and had instructed the electrical engineer to prepare estimates of the cost of laying the cables, also an estimate for remedying the humming noise at the generating station, for an additional boiler and steam set, and also for an extension of the switchboard. Mr. Proctor (the electrical engineer) in his last report states that there had been three new connections in the last fortnight, and a total of 41 customers.

New Zealand Cable Rates.—The tentative arrangement come to between the Eastern Extension, Australasia, and China Telegraph Company, Limited, and the Federal Government of Australia for applying to Victoria and Queensland the reduced rate now in force in the four contracting States will be extended to New Zealand, New Caledonia, Norfolk Island, and Fiji. Consequently the tariffs to those places on and after June 1 prox. will be as follows: for New Zealand, ordinary telegram 3s. 4d. per word, press telegram 1s. 2d. per word; for New Caledonia, ordinary, 3s. 8d. per word; for Norfolk Island, 3s. 2d. per word; for Fiji, 3s. 7d. per word.

Bournemouth.—The town clerk reported at the last Town Council meeting that the Board of Trade had declined to make an order in favour of the Corporation *re* Pokesdown lighting, and had granted an order to the company. The following resolution was passed: "(1) That in the judgment of the Council of the county borough of Bournemouth, being the governing body of the said county borough, it is expedient for such governing body to oppose a Bill to confirm, *inter alia*, a provisional order made by the Board of Trade under the Electric Lighting Acts, 1882 and 1888, and called the Pokesdown Electric Lighting Order, 1902, so far as the said order is concerned; (2) that the costs and expenses attending such opposition be paid out of the borough fund and borough rate of the said county borough."

Erith.—The Urban District Council's electric lighting station is to be opened next autumn. Mr. W. C. C. Hawtayne is the consulting engineer. A loan of £23,506 is authorised, being £4,527 for buildings, £7,696 for generating plant, £1,000 for meters and instruments, £8,965 for mains and sub-stations, and £1,318 other capital charges. The plant will consist of two Lancashire boilers by Spurr, Inman, and Co. of 160lb. pressure, and two W. H. Allen and Co.'s engines of 460 and 380 revolutions respectively, engines direct coupled to two International Electric Company's three-phase open-coil inductor type dynamos, with a frequency of 50, 2,800 to 3,000 voltage, and 50 kw. and 150 kw. respectively, and a two-pole shunt-wound direct-driven exciter. The street-lighting is on the three-phase alternate-current system at 200 volts, and will comprise nine arc lamps of 15 amperes and 440 16-c.p. or 32-c.p. incandescent lamps. Eight sub-stations will be placed in the streets. The charge for lighting will be 7d. per unit for the first hour and 3d. after.

Mexborough.—The Urban District Council's electric lighting station was opened on May 10. Mr. N. Waring is the resident engineer. A loan of £13,500 was authorised, distributed as follows: £1,500 for buildings, £3,500 generating plant, £750 meters and instruments, £5,500 mains and sub-stations, and £2,250 other capital charges. The plant consists of two Lancashire boilers by Tinkers, Limited, and Davy Bros., of Sheffield, respectively, and two Alley and Maclellan 90-i.h.p., engines direct coupled to two direct-current Mavor and Coulson's six-pole dynamos of 440 to 480 volts, with a total capacity of 100 kw., and Ashmore, Benson, Pease, and Co.'s accumulators, with a normal output of 270 kilowatt-hours and a maximum discharge rate of 100 amperes. The three-wire continuous system has been adopted, and the street-lighting will comprise 15 enclosed arc lamps and 215 32-c.p. incandescent lamps. One thousand yards of mains have been laid for public lamps.

Hull.—With regard to the annual statement of accounts of the Corporation electric lighting department, which appears in another column, Mr. A. S. Barnard, the city electrical engineer, states that owing to a reduction of ½d. per unit made March 31, 1901, coupled with general slackness of trade, the gross revenue is actually less than the previous year. The increase in the use of current is less than half the increase of the previous year, and the local rates have been increased 1s. 6d. in the pound, making an increased charge on the undertaking of nearly £200. The year's revenue has been charged with three years' payment to sinking fund in respect of one item—viz., £8,717 difference of expenses in issue of stock—this being a net charge for the year of £701. When the loan was floated a full quarter's dividend of 15s. was paid when only 6s. 9d. had been earned. This means another net charge of £516 on the year's working. Furthermore, during August a phenomenal storm, when nearly 3in. of rain fell in the space of one hour, deluged the engine-room and did damage to the buildings, machinery, and mains to the extent of over £500.

Swansea.—The engineer's last report states that the number of consumers on the books is 213, with the equivalent of 24,775 8-c.p. lamps. Mains are to be extended to the following districts—viz.: Plymouth-street, etc., estimated cost £90; Little Wind-street, estimated cost £48; Fisher-street, estimated cost £93; Ffynone and St. James's gardens; and an estimate of the cost of laying a distributor along St. Helen's-road to the hospital is being prepared. The Corporation will make an offer to supply electric power to the Hafod Isha Works upon the following terms—viz.: 15,000 units at 1½d. per unit, or a minimum of 200,000 units per annum at 1¼d. per unit, delivered through a meter at two terminals on the property of the Anglo-French Nickel Company, the company to agree to take a supply for at least three years. The Telephones Committee have received 398 agreements, exclusive of 117 written promises, to support the municipal telephone scheme. The Postmaster-General being unwilling to meet the desire of the Council with regard to the rates for telephones, the committee have resolved to interview the Post Office solicitor, and urge upon him the desirability of retaining the rates originally proposed. The Corporation desire the minimum charge for the telephone service to be £5, but the Post Office suggested that the rate should be £4.

Bolton.—The details of the revenue and costs of the electricity department for the year ending March 31, 1902, work out as follows, according to a statement prepared by the electrical engineer, Mr. Arthur A. Day: Board of Trade units sold—private lighting, 905,928 units at 3·80d., £14,460. 15s. 8d.; public lighting, 17,467 units at 3·10d., £225. 17s. 7d.; power, 197,674 units at 1·45d., £1,199. 6s. 3d.; tramways, 1,999,640 units at 1·50d., £12,497. 15s.; meter rents, £501. 15s. 3d.; motor rents, £107. 16s. 11d.; profit of fittings department, £806. 10s. 7d.—total revenue, £29,799. 17s. 3d. The expenditure was as follows: coal, £5,686. 2s. 9d. (·436d.); oil, waste, and water, £803. 3s. 2d. (·062d.); wages, £2,413. 4s. 2d. (·186d.); repairs, £1,563. 19s. 2d. (·120d)—works cost, £10,466. 9s. 3d. (·804d.); rents, rates, and taxes, £906. 9s. 9d. (·070d.); management expenses, £1,107. 14s. 6d. (·085d.)—total cost, £12,480. 13s. 6d. (·959d.); interest, £4,912. 8s. 5d. (·378d.); depreciation, £7,655 (·589d.)—inclusive cost, £25,048. 1s. 11d. (1·926d.). The total revenue was £29,799. 17s. 3d., and the inclusive cost £25,048. 1s. 11d. The balance (net profit) amounted to £4,751. 15s. 4d. The sum of £3,850 was voted in relief of rates, and £901. 15s. 4d. carried forward.

Dudley.—Mr. E. A. Sandford Fawcett has held an enquiry into the application of the Corporation for sanction to borrow £22,000 for electric lighting purposes. Mr. H. C. Brettell (town clerk) explained that the loan was to enable the Corporation to meet their statutory obligations with reference to electric lighting in the borough, and was the third in connection with the electrical undertaking, the previous loans being £8,500 and £33,000 respectively, the former of which was required to enable the Town Council to fulfil their contract with the tramway company, and the latter for the provision of the power station. The first year's operations resulted in a loss of £80 6s. 10d., and last year there was a net profit, in excess of repayment of principal and interest, of £92. Mr. R. Wilson (consulting electrical engineer) said the tramways belonged to a company, but the Corporation were under a contract to purchase them at the expiration of the lease. The company would continue to work them under a lease from the Corporation, and were under a perpetual arrangement to take the current from the Corporation at a price to be determined every five years. The power station had now a capacity equal to 700 kw., and in order to meet the increasing demand it was proposed to lay down a 500-kw. machine and dynamo, the remainder of the money being required for the provision of street cables.

East Sussex County Asylum.—Mr. Albion T. Snell is the consulting engineer for a compact plant which is being laid down by Messrs. J. E. Spagnoletti and Co., of Goldhawk-road, W. The plant will consist of one steam balancing set of engines and dynamos, direct coupled, each dynamo capable of giving 30 kw. at 200 to 205 volts; also two sets of engines and dynamos each capable of giving 60 kw. at 400 to 410 volts for lighting and 400 to 450 volts for traction. The dynamos will be of the multipolar type, and the engines of Belliss and Morcom's make. Two batteries of 226 cells of Chloride accumulators, capable of giving 70 amperes for seven hours and 120 amperes for four hours, will also be provided. The wiring is for 1,500 16-c.p. lamps and 800 8-c.p. lamps. Nine motors are to be supplied for power purposes. Power will also be supplied to a light railway between the asylum and Hellingley Station, a distance of 1,900 yards, on the overhead trolley system. Brackets from side poles 40 yards apart will be used. A suitable main traction switchboard is supplied. The principal switchboard is to be of Spagnoletti's central-station, low-tension, three-wire design, the general arrangement being such that one or more of the steam dynamos can be used for supplying the lights and motors, aided at the same time by the steam or motor balancer and booster for charging accumulators at full rates. The latter are to be in circuit at all times.

Australian Power Transmission.—Another large power transmission scheme projected in Victoria is that of working the extensive mines in the large and well-paying Walhalla district by a plant to be erected on a central site—at Mormon Town, on the Thomson River. This river has an excellent fall and a good permanent water supply, and is, therefore, especially well adapted for the working of power plant. Those interested could not do better than consult a report which has recently been issued by the Department of Mines of that State. The report is the outcome of a special survey planned by the Government geologist, Mr. James Stirling, at present representing the department in London, and signed by Mr. H. Herman, B.C.E., F.G.S., acting Government geologist. The report abounds in plans, sections, and plates, and is far above the usual Blue-book in details of stratifications and general underground work. The field work has been carried out by Messrs. V. R. Stirling and O. A. L. Whitelaw. Mr. V. R. Stirling was a most able officer, whose sudden death a few days ago—cutting short a most promising career—is much deplored by all who knew him, and earnest sympathy is felt for his father. All the photographs in the report are Mr. Stirling's work, and they are remarkable specimens of underground work. Most interesting amongst the plans and sections is a sheet, 6ft. by 2ft., showing the general geological structure of the field where it is proposed to instal the power plant.

Leeds.—The generating engines at the Corporation electric lighting works in Whitehall-road will shortly be laid down. In building extensions and additional plant the Corporation are spending about £160,000, and it is anticipated that by this expenditure they will be able to meet the demand for electricity for some time to come. The extensions include a large engine-house, capable of holding 10 generating sets of 2,500 h.p. each, with the necessary boilers, condensing plant, etc. Messrs. J. and M. McLaren, of Hunslet, secured the contract for one of the two engines at first required to be placed in the new station. The engine is now finished, and has been inspected by members of the Corporation Lighting Committee and engineers in the

Digitized by Google

city. It is a triple-expansion, high-speed, enclosed engine, capable of developing a normal power of 2,500 i.h.p., with a maximum for an emergency of 3,000 i.h.p. It is the most powerful electric lighting engine ever built in Leeds. Weighing 150 tons, without flywheel, the engine makes 200 revolutions per minute. The boiler pressure is 180lb. on the square inch, but all is strong enough to admit of a pressure of 200lb. The structure is distinguished by the comparatively small number of working parts and the simplicity of its construction, and the makers assert that economy and steadiness at all loads will characterise its operations. So far, a steam consumption of 11·8lb. per indicated horse-power per hour, equal to a coal consumption of less than 1¼lb. per indicated horse-power per hour, has been obtained.

Leatherhead.—The buildings of the Leatherhead and District Electricity Company are progressing. The boiler-house is equipped with two Davey-Paxman's high-pressure boilers, with superheaters, thus securing the maximum economy. In the engine-house are two vertical 50-h.p. engines coupled direct to the dynamos. The accumulator batteries are said to be of exceptional capacity, so that in the event of unforeseen accidents to any part of the machinery, the lighting of the town and of residences will be in no way affected. It is proposed to commence the laying of the mains at once. For lighting, 7d. per unit will be charged to ordinary consumers, and 4d. per unit for motive power. The company propose at the outset to wire for a limited number of consumers free of charge up to four lights, and to put in penny-in-the-slot meters. The company have offered to light the streets electrically, and to carry out the same scheme for public lighting which Messrs. Handcock and Dykes, the engineers to the present company, recommended the Council to adopt some time ago when they were discussing whether they should themselves carry out the undertaking. They offer to supply the current for public lighting as it was then calculated the Council could generate it for. The company have already secured a contract to light the new blind school with the equivalent of 1,200 8-c.p. lamps, the supply to commence on July 1 next. By this date the company will also be in a position to supply other intending consumers. The building is being carried out from designs prepared by Mr. J. R. Harding, C.E., of Epsom, by Mr. H. Skilton, of Leatherhead. Messrs. Geipel and Lange are responsible for the engineering part of the undertaking, and Messrs. Glover and Co., of Salford, are the contractors for the laying of the mains, the consulting engineers being Messrs. Handcock and Dykes.

Presentations.—Mr. W. F. Stamp, A.M.I.E.E., late assistant electrical engineer to Wimbledon Council, having been appointed to the post of chief assistant electrical engineer to the Devonport Corporation, was entertained by his professional friends at Frascati's Restaurant on Thursday last week. Mr. J. W. A. Binner, chief assistant engineer to the Bermondsey Borough Council, in presenting Mr. Stamp with a dressing case on behalf of the company present, congratulated him on his appointment and wished him every success. A silver cigarette case was also presented to him from the working staff of the Wimbledon electricity works, as a mark of their great appreciation of his courteous treatment, and fair dealing received at his hand. An address from the men, wishing him every success, accompanied the gift. Mr. Stamp left Paddington on Saturday, when he was accorded a most hearty send off; Mr. A. E. Young making a further presentation of a silver match box on behalf of a few personal friends. At Rotherham last week the borough electrical engineer, Mr. Edward Cross, was the recipient of a handsome present, consisting of a silver afternoon tea set and silver-mounted oak tray, suitably inscribed, from the staff and employés on the occasion of his marriage. His Worship the Mayor (Alderman D. L. Winter), who made the presentation on behalf of the employés, congratulated Mr. Cross on the excellent feeling that existed between himself and the staff. He was sure his colleagues in the Council had the utmost confidence in their electrical engineer. The majority of the Council anticipated a loss in the working of the department, and he thought it augured well for the future of the undertaking that in the comparatively short period of 10 months during which their works had been in operation they had not only paid their expenses, but actually made a small profit.

PROVISIONAL PATENTS, 1902.

MAY 14.

11018. Improvements in lampholders or sockets as used in lamps for electric lighting and the like. John Westwood Lea and John Hall Perrins, Midland Works, Bracebridge-street, Birmingham.

11021. Improvements in electricity supply meters. Rankin Kennedy, 42, Markham-avenue, Leeds.

11044. Improvements in and connected with electric arc lamps. John Owen Girdlestone and Carl Frederik Grimur Thorkelin, 16, Davies-street, Berkeley-square, London. (Complete specification.)

11067. Improvements in electrical instruments for signalling on railways. Edward Tyer, Frederick Thomas Hollins, and Frederick William Leake, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

11068. Improvements in apparatus for actuating the electrical controlling appliances of the motors of electric railway motorcars. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktiengesellschaft, Germany.)

11072. Improvements in switches for electric circuits. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (James J. Wood, United States.) (Complete specification.)

11073. Improvements in means for controlling electric circuits. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (James J. Wood, United States.) (Complete specification.)

11074. Improvements in winding forms. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. Julius W. Sundskog, United States.) (Complete specification.)

11075. Improvements in electric switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edward M. Hewlett, United States.) (Complete specification.)

11076. Improvements in electric arc lamps. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edwin W. Rice, jun., United States.) (Complete specification.)

11077. Improvements in supports for high-tension electric conductors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Asa F. Batchelder, United States.) (Complete specification.)

11078. Improvements in electric arc lamps. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Walter C. Fish, United States.) (Complete specification.)

11079. Improvements in cut-outs for electric conductors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Pendleton G. Watmough, United States.) (Complete specification.)

11080. Improvements in multipolar electric switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Howard R. Sargent, United States.) (Complete specification.)

11081. Improvements in electric starting rheostats. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Frederick Mackintosh, United States.) (Complete specification.)

11082. Improvements in third-rail insulators for electric railways. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Samuel B. Stewart, United States.) (Complete specification.)

11085. Improvements in electric cranes. Stothert and Pitt, Limited, and Ebenezer Evans, 24, Southampton-buildings, Chancery-lane, London.

11086. Improvements in and relating to electric switches. Denis Ripley Broadbent, 322, High Holborn, London.

11095. Improvements in or relating to coupling devices particularly applicable for coupling a dynamo to a centrifugal pump. Maurice Auguste Eudelin, 111, Hatton-garden, London.

11101. Improvements in electric clocks. Otto Romanze, 37, Essex-street, Strand, London.

11102. Improvements relating to electric heaters and rheostats. Max Carl Krueger, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MAY 15.

11127. Improved apparatus or means to be employed in conjunction with trolley arms in applying roofs or covers over the tops of electric tramcars and the like. John Thomas Trainer, 32, John William-street, Huddersfield.

11134. Improvements in electric arc lamps. August Eckstein and Arthur Ernest Angold, Peel Works, Adelphi, Salford, Manchester.

11139. Improvements in or relating to the electrical igniters of gas and similar explosive vapour motors. Alfred Rowe Bellamy, 5, John Dalton-street, Manchester.

11159. Spring roller for regulating the height of electric light pendants. Wilfrid Emerson, 45, Earl-street, Grimsby.

11160. Improvements in electric arc lamps. Arthur Kirby and Alfred James Kirby, 226, High Holborn, London.

11165. Improvements in switch-box apparatus used for testing, standardising, or calibrating electrostatic instruments, and in measuring electric currents thereby. George Leonard Addenbrooke, 37, Essex-street, Strand, London. (Complete specification.)

11177. Improvements in apparatus for opening and closing electric circuits. Hugo Hirst and Charles Frederick Trippe, 71, Queen Victoria-street, London.

11188. Improvements in continuous-current dynamos. Paul Néty, 65, Chancery-lane, London.

11197. Extracting electricity from the atmosphere and storing it. James Fenton, Albert du Lac, and Arthur Jonckheere, 70, Oak Hill-road, Wandsworth, London.

11206. Improvements in or relating to arc lamps. Friedrich Engelhardt, 18, Buckingham-street, Strand, London.

11209. Improvements relating to electrical conduit systems for tramways. Frank Boulton Aspinall and James Douglas Dallas, 6, Breams-buildings, Chancery-lane, London.

MAY 16.

11240. Improved electric switch. John Crawford Macalester, Box 23, Athenæum, Glasgow.

Digitized by Google

11249. Improved sliding pendant for electric lighting. James Milne, Milton House Works, Edinburgh.

11269. Improvements in wireless signalling. John Munro, St. John's-grove, Croydon.

11286. A new or improved galvanic cell. Gerhard Bodo Puchmuller and George Pearson, 70, Chancery-lane, London. (Complete specification.)

11290. Improvements in electric switches and regulating sockets, chiefly designed for use in connection with incandescent electric lamps. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (William Peyton Pinckard, United States.) (Complete specification.)

11313. Improvements in and relating to the transmission of electrical impulses. Ludwig Walter and Peter Walter, 322, High Holborn, London.

11323. Improvements in electricity meters. Leonard James Eron and John William Flower, 47, Lincoln's-inn-fields, London.

11324. Improvements in electricity meters of the kind known as two-rate meters. Leonard James Aron and John William Flower, 47, Lincoln's-inn-fields, London.

MAY 17.

11339. Improvements in portable telephonic apparatus for the use of persons with impaired hearing. William Edwin Heys, 70, Market-street, Manchester. (The Hutchison Acoustic Company, United States.) (Complete specification.)

11340. Improvements in dry or semi-dry cells of primary or secondary electric batteries. William Edwin Heys, 70, Market-street, Manchester. (The Hutchison Acoustic Company, United States.) (Complete specification.)

11342. Improvements in charging switches for secondary electric batteries. William Edwin Heys, 70, Market-street, Manchester. (The Hutchison Acoustic Company, United States.) (Complete specification.)

11357. Improvements in electricity meters. Knowles Anderson, 65, Albion-street, Leeds.

11369. Improvements in electric governing devices. John Joseph O'Connor and William Oliver Septimus Hilditch, 55, Market-street, Manchester.

11374. A new system of electric traction. Baptistin Cruvellier, Commercial-street, Halifax. (Complete specification.)

11377. Improvements in fittings for metallic conduit systems of electric wiring. Lawrence Maxwell Waterhouse and the Simplex Steel Conduit Company, Limited, 34, Castle-street, Liverpool. (Complete specification.)

11393. Improvements in automatic apparatus for controlling and operating the points of electric railways and tramways. Thomas Bell Stewart, William Herbert Turner, and Rowland Edward Dixon, 8, Quality-court, Chancery-lane, London.

11395. Improvements in or applicable to rheostat switches for controlling electric currents. William Royston Laidlaw and George Hamer Scholes, 70, Deansgate, Manchester.

11404. Improvements in electric fuses. Oliver Leopold Peard, 24, Southampton-buildings, Chancery-lane, London.

11416. Improvements in overhead conductors for electric tram and railways. Edouard Dussek, 39, Hillcrest-road, Acton, London.

11423. Improvements in electric clam dredges. Ephraim Chaquette, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

11427. A new or improved endless electric conveyor for conveying tin plates from the bath of molten metal to a suitable or desirable place. John Baxter, Oliver Clark, and Charles Hillman, 9, Regent-street, London. (Complete specification.)

MAY 20.

11454. Improvements in register dials for gas, water, and electricity meters. Claud Carew-Gibson, 15, Claremont-road, Surbiton.

11460. Improvements in and relating to the electrical propulsion of tramway cars, railway carriages, and the like. Robert Cleghorn Thomson, 96, Buchanan-street, Glasgow. (Donald Kempt, Argentine Republic.)

11487. Improvements in electric cables. George Harrison, of D. Young and Co., 11, Southampton-buildings, Chancery-lane, London. (Kabelfabrik Actien-Gesellschaft, Austria.) (Complete specification.)

11489. Improvements in starting devices for alternating-current induction motors. British Thomson-Houston Company, Limited, and Hans Sigismund Meyer, 83, Cannon-street, London.

11499. Improvements in and relating to electric low-water alarms for steam-boilers. George Croydon Marks, 18, Southampton-buildings, Chancery-lane, London. (George Fuller, United States.) (Complete specification.)

11500. Improvements in multiple switches. George Croydon Marks, 18, Southampton-buildings, Chancery-lane, London. (The Cutler-Hammer Manufacturing Company, United States.) (Complete specification).

11510. Improvements in electric incandescent lamps with rare earth filaments. William Alfred Crook and Edward Mines, 6, Lord-street, Liverpool.

11508. Improved process for the preparation of electrodes or secondary batteries. William Phillips Thompson, 322, High Holborn, London. (Akkumulatoren und Elektricitäts-Werke Aktiengesellschaft vormals W. A. Boese und Co., Germany.) (Complete specification.)

11509. Process for the production of electrodes for secondary batteries. (Akkumulatoren und Elektricitäts-Werke Actiengesellschaft vormals W. A. Boese und Co., Germany.) (Complete specification.)

11516. Improvements in apparatus for electrically operating tools. Herbert John Haddan, 18, Buckingham-street, Strand, London. (James Stewart Andrews and William Matthew Simpson, United States.)

11523. Method of and means for transmitting electrical energy in works for traction purposes. Max Deri, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MAY 21.

11567. A new and improved receiver for wireless telegraphy. Louis Heathcote Walter, 83, Holland Park-avenue, London.

MAY 22.

11640. Improvements in elastic cushions or buffers for electric light shades and the like. Alexander Marr, 18, Cawdor-road, Fallowfield, Manchester.

11668. Improved manufacture of electric accumulators. Albert Schmidt-Predari, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

11683. Apparatus for generating and utilising electric energy. William Speirs Simpson, 173, Fleet-street, London.

11692. Improvements in wireless telegraphy. Edward Pruden Thompson, 322, High Holborn, London.

MAY 23.

11722. An improved trolley head and arm for overhead electric wires and a safety appliance for rendering broken electric wires harmless. Jasper James Carter, 4, Vergemont Hall, Clonskeagh, co. Dublin.

11725. Improvements in or relating to metallic conduits and fittings for electric cables and the like. Laurence Maxwell Waterhouse and the Simplex Steel Conduit Company, Limited, 34, Castle-street, Liverpool.

11728. An improved electrical switch. Oliver Pearson, 2, Akenside-hill, Newcastle-on-Tyne.

11765. A method of measuring temperature at a distance by electrical means. Charles William Scott Crawley and Alexander Pelham Trotter, 44, Castletown-road, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published June 12

1901.

3935. Laying of underground conductors for distribution of electrical energy. Jones and Davis.

10166. Printing telegraph receivers. Boult. (Joy Printing Telegraph Company.)

10766. Electromagnetic selectors for loom jacquards or other apparatus. Macquisten.

11931. Regulating and controlling the speed or power of electric motors. Allcroft.

13010. Telephone and bell set. Byng and Bell.

13078. Electric accumulators. Gibbs.

13402. Self-exciting alternating-current dynamos. Latour. (Rights under Sec. 103 not granted.)

13666. Lamp-holders for electrolytic lamps. Drake and Nernst Electric Light, Limited.

14165. Manufacture of carbon electrodes and of coke. Pohl.

14486. Process and apparatus for the manufacture of wrought iron, steel, and cast iron by electric heating. Imray. (Soc. Electro-Metallurgique Française.)

14643. Electric furnace arranged for being oscillated or tipped. Imray. (Soc. Electro-Metallurgique Française.)

14822. Electrolytic apparatus. Rhodin.

16460. Electric alternating-current transformers and accessories thereto. Wilkinson.

18597. Electric regulating apparatus. William Jared Clark. (James B. Foote.)

20497. Cable terminal boxes for electricity supply purposes. Wilkinson.

26484. Third railway conductors for electric railways. Lake. (Central Electric Construction Company.)

26485. Third-rail conductors for electric railways. Lake (Central Electric Construction Company.)

1902.

1984. Electric transformer. Stutchbury and Gorick.

2701. Telephone line jacks. Lambert.

7447. Electric transmission of power. Otis Elevator Company, Limited. (Otis Elevator Company.)

8009. Submarine and other war vessels, and especially those carrying torpedoes. Hardingham. (Electric Boat Company.)

8487. Transmitting devices for electric telegraphic and like apparatus. Justice. (Rowland Telegraphic Company.)

MISCELLANEOUS.

The following traffic returns are also reported:

Anglo-Argentine, £377 decrease.
Barcelona Ensanche y Gracia, £96 decrease. Barcelona £323 increase.
Brisbane, £125 increase (month of March, £10,934; increase, £1,789).
Buenos Ayres and Belgrano Electric (month of April, receipts £11,872; decrease £615), £8 decrease.
Calcutta, £246 increase.
Cape Town (month of March), receipts, £17,888; expenditure, £7,343.
Isle of Thanet Electric, £280 increase.
Mexico Electric (month of April), receipts, £19,350; expenditure, £10,620.
Perth Electric, £227 increase.
Port Elizabeth (month of March), receipts, £3,818; expenditure, £1,947.

Supplement to "The Electrical Engineer,"

MAY 30, 1902.

ELECTRICAL TRACTION ON STEAM RAILWAYS IN ITALY.*

BY PROF. C. A. CARUS-WILSON, M.A., MEMBER.

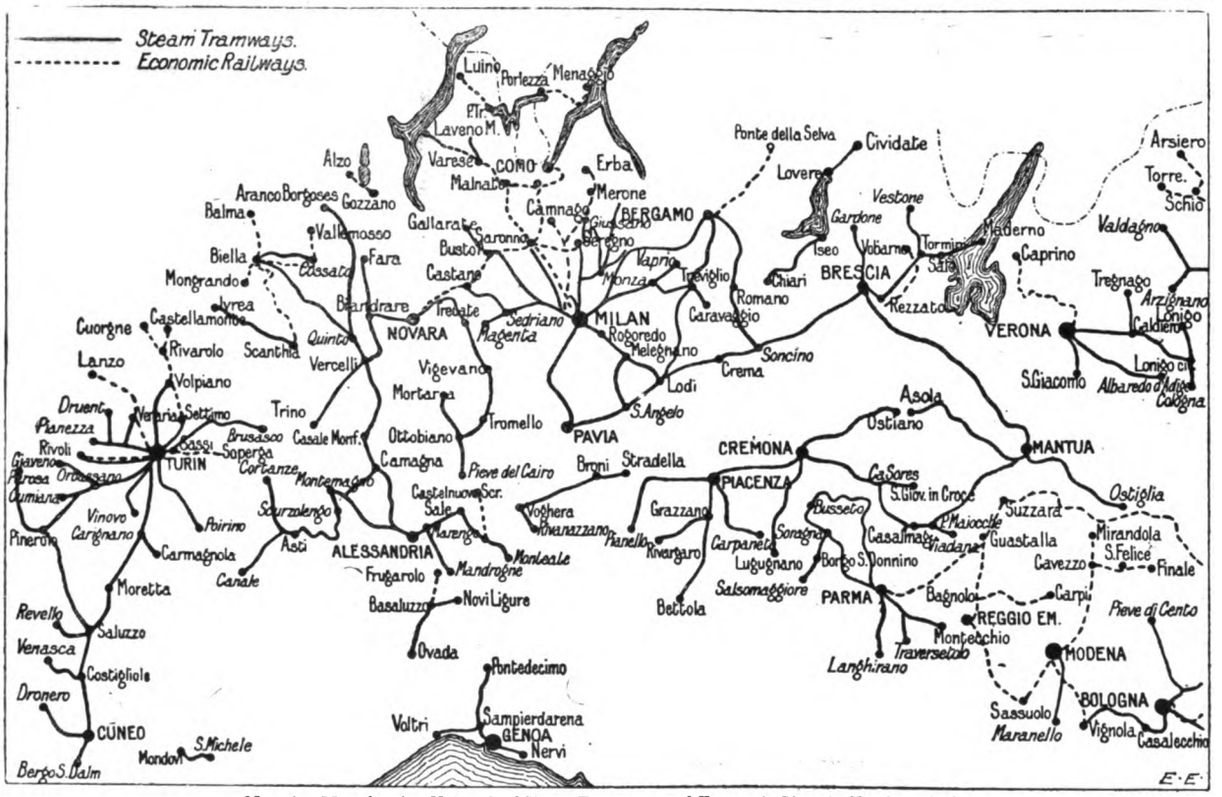
Italian Railways.

The Adriatica and the Mediterranean Railway Companies together work 80 per cent. of the railways in Italy, the former serving the whole of Eastern Italy from Venice to Brindisi, and the latter the whole of Western Italy from Turin to the extreme south. The two systems have their chief connecting points at Milan, Florence, Rome, and Naples. The number of miles of line worked by each company is about the same, nearly 3,690 miles by the Mediterranean and 3,620 by the Adriatica. Each of these companies, therefore, works about as many miles of line as the Great Western and the Great Northern Companies put together. The railways are now being worked under an arrangement with the Italian Government, by which the Government gives the companies an annual subsidy in return for a certain proportion of the receipts. For the year 1900 the Adriatica Company received from the Government a subsidy of £2,166,000, while it paid to the Government a sum equal to 40 per cent. of the total receipts, amounting to £2,040,000, the balance to the credit of the company being £126,000. This arrangement comes to an end in 1905, when the Government has the option either of buying out the companies or of coming to a fresh arrangement with them. For a long time past the Italian railways have been suffering from the competition of tramways and economic lines, which have provided a cheaper and more frequent service, seriously affecting the traffic on the main lines in spite of every effort made to minimise the injury thus caused. The map (A) shows the network of steam tramways and economic lines that has spread over Northern Italy; these not only radiate from most of the large towns, such as Milan, Turin, Verona, etc., but also serve as links to connect one town with another, as, for instance, the line connecting Milan with Pavia, which is 20 miles long, and that connecting Brescia and Mantua, which is 43 miles long. The railway companies have come to the conclusion that the remedy for this competition lies in providing, by means of electricity, a service of short trains running frequently at high speeds. This paper will contain an account, written from an economic rather than from a technical standpoint, of what is being done towards carrying out this object, with some comparisons between the conditions of railway working in Italy and in England.

The Adriatica Railway.

The Adriatica Railway Company has already equipped electrically that portion of its system running from Lecco to Colico, and thence to Sondrio and to Chiavenna (see Map B). The intention is to extend the system ultimately to Milan. Meanwhile the electrically-driven trains are to work their own way as far south as Lecco, and to be hauled thence to Milan by steam locomotives. Trains are now running experimentally, but not yet in actual service. The total distance at present electrified amounts to 66 miles, all of single track, a large proportion between Lecco and Colico being in tunnel. A profile of the line is given in Fig. 1. The hydraulic power-house, with turbines of 6,000 h.p., is at Morbegno, water being taken from the River Adda. Three-phase current is generated at 22,000 volts, and carried by overhead conductors to nine transformer stations, where it is transformed down to 3,000 volts and taken to the two trolley wires, the rail forming the third conductor, and thence direct to polyphase motors on the cars.

The motorcars, of which a view is given in Fig. 2, are 57ft. long, weigh 53 tons unloaded, and have seating accommodation for 56 passengers. Each car is provided with two high-speed motors of 150 h.p. and two low-speed motors of 75 h.p. each, weighing 3·8 tons and driving direct without gearing. Full speed is 37 miles an hour. The four motors are used in cascade connection at starting; at half speed the two low-speed motors are switched out, and the car is driven by the two high-speed motors alone at full speed. On all grades over 1 per cent. the motors are connected in cascade, and the speed thus



MAP A.—Map showing Network of Steam Tramways and Economic Lines in Northern Italy.

halved. The trailers used are passenger carriages of the ordinary type. The goods traffic is to be hauled by electric locomotives.

The company is introducing a new "economic" system for working the line, by which they hope to reduce the traffic expenses, 80 per cent. of which is accounted for by the wages and salaries of the *personnel* at the stations. This system has been in operation on other parts of the company's lines, and has been found to work well, as, for instance, on the section of line, 27 miles long, between Bologna and St. Felice, part of the projected line from Bologna to Verona. In this system the stations are divided into "control" stations and "section" stations. On the Lecco line there are six of the former and eleven of the latter. The responsibility for the control of the traffic rests with the *personnel* at the "control" stations, the agents at the "section" stations having no direct responsibility for the safe conduit of the traffic which depends entirely on an automatic block system operated by an electrical apparatus which the agent has to attend to and keep in working order. Each "section" station is in telephonic communication with the nearest "control" station, to which all questions relating to rates, regulations, etc., can be referred. By this means a considerable reduction in the expense of the *personnel* at the stations is rendered possible.

The block system employed is the Webb and Thompson staff system, supplemented by an electric interlocking apparatus invented by Signor Olper, the controller of telegraphs in the Adriatica Railway Company, combined with an arrangement by which the trolley line at every station is divided into sections, each controlled by a switch, the opening and closing of which takes place simultaneously with the

* Paper read before the Institution of Electrical Engineers, May 15.

Digitized by Google

movement of the corresponding signal, so that it is impossible for a train to run on to a section against signals.

The Mediterranean Railway.

The Mediterranean Railway Company is equipping electrically the whole of the line from Milan to Gallarate, and thence to Varese, Porto Ceresio, Laveno, and Arona. Some idea of the importance of the change now in progress may be gained from the fact that the passenger receipts from these sections of line amount to about 2 per cent. of the receipts for the whole Mediterranean system. The total length of line is 81 miles, made up of sections as given in Table V. Of the whole distance, all is of single track except the length from Milan to Gallarate, which is of double track. The maximum grades and minimum curves are given in the table. A profile of the line is given in Fig. 3, and a plan in Fig. 4.

The power-house is at Tornavento, about seven miles from Gallarate. Current is at present being supplied from a steam generating plant, but a water-driven plant is in course of construction close to the steam power-house, from which the whole line will ultimately be worked. Turbines of a total of 11,000 h.p. will be driven by water taken from the River Ticino. The power is transmitted as three-phase current at 12,000 volts to sever sub-stations along the line, where the pressure is reduced from 11,000 to 420 volts, and the current is transformed in rotary converters to direct current at 650 volts. From the sub-stations the current is taken to an insulated third rail, as shown in Fig. 5. The motorcars on the Varese line, shown in Fig. 6, weigh 40 tons unloaded, and have accommodation for 63 passengers seated and 12 standing. Each motorcar is driven by four 150-h.p. motors, on the usual one-hour rating, and is geared with a 3 to 1 ratio to 41in. driving wheels. Full speed on a level is 56 miles an hour. Each motor weighs 2·5 tons. The trailers weigh 27 tons empty, and have accommodation for 63 passengers seated and 27 standing. The goods traffic is to be hauled by electric locomotives. The electric trains are now running and in regular operation as far as Varese, though the service of trains as contemplated is not yet complete.

Table I.—Comparing the Weight, Power, and Dimensions of the Polyphase Motorcars on the Lecco Line with the Direct-Current Motorcars on the Varese Line.

—	Total weight empty.	Length of frames.	Seats.	Number of motors.	Maximum H.P. of each.	Total maximum H.P.	Weight of four motors.	Full speed on level.

Working Expenses and Receipts.

The working expenses of the Italian railways are given in Table II. These figures actually refer to the Adriatica Railway, but as the corresponding figures for the Mediterranean Railway are almost the same, they may be taken as representing the cost of running on either of the great systems. To afford a comparison, the figures for the cost of running an English railway are placed in the same table. A distinction has been made between those expenses which do and those which do not vary with the number of trains run. Thus to the locomotive expenses, comprising wages of driver, water, oil, and repairs, have been added the cost of conductors' wages and carriage repairs. All these expenses vary with the number of trains run, and are, therefore, dealt with apart from those, such as the maintenance of the line, which do not so vary.

Table II.—Running Expenses per Passenger Train Mile.

	English. d.		Italian. d.
1. Coal	1·72	...	5·30
2. Wages of driver and stoker	3·81	...	3·18
3. Wages of conductor	1·52	...	2·08
4. Water, oil, etc.	0·77	...	0·60
5. Repairs, locomotives	2·39	..	3·52
6. Repairs, carriages	2·83	...	6·01
Total	13·04	...	20·69

Note.—English items 2, 4, 5, and 6 from official returns for the Great Northern Railway for 1900. Italian items 2, 3, 4, 5, and 6 from official returns of the Adriatic Company for 1899. Item 3 under English costs, obtained by taking the wages of driver, firemen, and conductor in the proportion of 42s., 22s., and 25s.

The coal consumption on an English railway is taken at 40lb. per train mile, and the cost at 8s. per ton. The actual consumption of coal on the locomotive on the Italian railways is given in the official reports as 41lb. per train mile. The statistics draw no distinction between the weight of an average goods train and that of an average passenger train, but the passenger train mileage is stated to be 68 per cent. of the whole train mileage. Taking the weight of coal per passenger train mile to be 70 per cent. of that per goods train, the coal consumption per passenger train mile would be 36lb., which brings the cost, at 27s. per ton—the price paid in 1899—to 5·3d. per train mile.

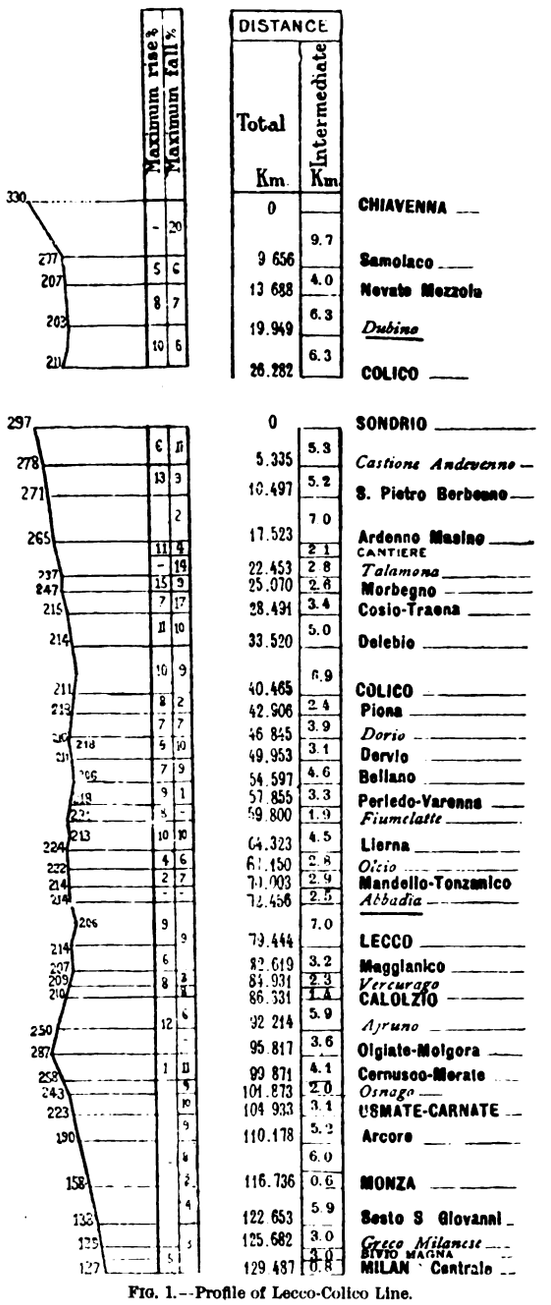

FIG. 1.—Profile of Lecco-Colico Line.

In order to compare the running expenses with the fixed expenses, they have both been reduced to pounds per mile per annum, and placed in Table III., together with the receipts estimated in the same way. The running expenses of an Italian railway constitute a far larger proportion of the total expenses than is the case on an English railway, the percentages being 62 in the former case and 42 in the latter. The proportion of passenger to goods receipts is nearly the same, while the sum of all the expenses is 70 per cent. of the receipts in Italy and 65 per cent. in England. The receipts given for the Italian railways refer to the Adriatica system as a whole, and are greater than the receipts of the lines that are now being electrified. Thus the passenger receipts for the section Lecco-Colico are only £380 per mile per annum, for the section Sondrio-Chiavenna £220, whereas for the section Milan-Varese-Arona-Laveno the passenger receipts are £600 per mile per annum. The most profitable section in the Mediterranean Company's system is the line from Milan to Genoa, which is six times as profitable as the average for the whole system; the most profitable on the Adriatica system is the line from Milan to Como, the continuation of the St. Gothard Railway, a line common to the two systems, and yielding to each railway 3½ times the average receipts per mile on the Mediterranean. The expenses of maintenance, traffic, and central administration on an Italian railway amount to £421 per mile per annum, about one-sixth of what it is in England. Of the item for traffic expenses in Italy, £213 per mile is for stations expenses, out of which again £170 per mile is for the *personnel* at the stations. The Adriatica Company is seeking to reduce this item by the adoption of the "economic" system of working the line referred to above.

Fares.

The fares charged on the various railway lines in Italy are given in Table IV. Column A gives the through express fares on the main lines, and column B the fares for the so-called omnibus trains which stop at all stations. Column C gives the reduced rates charged for omnibus trains on certain sections of the main lines, those, namely, where the competition with the tramways and economic lines is most keenly felt. Thus on the lines Milan-Gallarate-Varese, where there is direct competition, reduced rates are charged. The rates in the economic lines are given in column E, while the tramway rates will be found in column F. The rates in column E cover both omnibus and express trains, whereas the "reduced" rates are exclusively for omnibus trains, so that the main lines do not offer such a good service for the same money as the economic lines, even at the reduced rates.

TABLE IV.—Showing the Passenger Fares, in Pence per Mile, Charged on the Different Italian Lines.

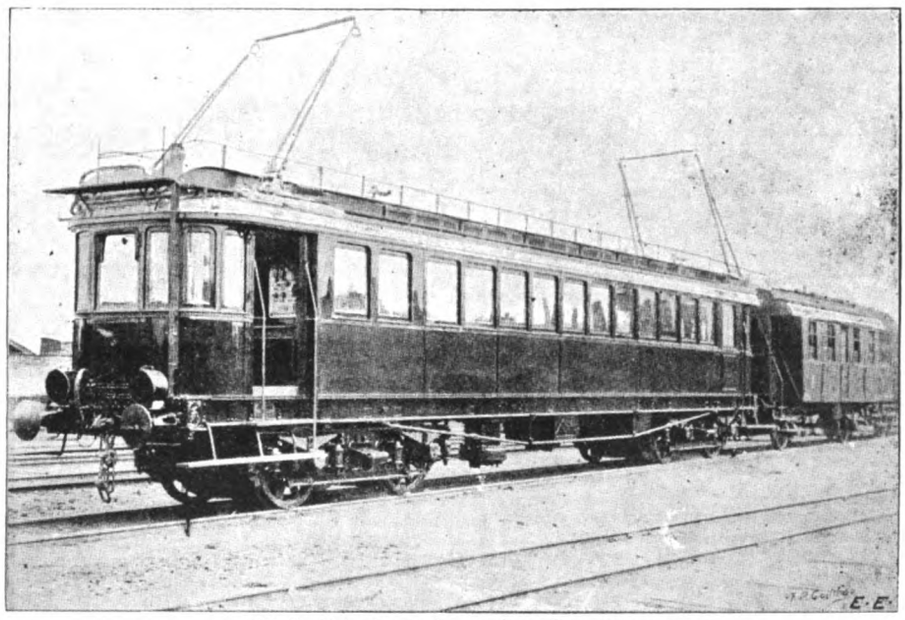

FIG. 2.—Motor Car used on the Lecco-Colico Line.

NOTE.—The figures in this table are obtained from the same sources as those in Table II. "Per mile" means per mile of line, regardless of the number of parallel tracks.

The Train Service.

The service of steam trains that formerly ran on the Milan-Varese line is given in Table V., with the time occupied in covering the

Digitized by Google

different sections. This may be compared with the new service of electric trains, particulars of which are also given in the table. Thus on the line from Milan to Gallarate the schedule speed has been nearly doubled and the frequency increased 3·5-fold. On the line from Gallarate to Varese the speed has been increased 75 per cent. and the frequency about four-fold. The old trains, hauled by steam locomotives, have been replaced by trains of about half their weight, consisting of motorcars and trailers, the normal train consisting of one motorcar and one trailer, weighing together 67 tons unloaded, and capable of carrying 165 passengers, or about one-half the accommodation of the steam-driven trains. The carrying capacity of this portion of the line, in passenger miles, has thus been increased 75 per cent. Between Gallarate and Arona and between Varese and Porto Ceresio the speeds have not been increased on account of the

The Cost of Working the Electric Service.

The cost of running the new electric service on the Milan-Varese line may be estimated approximately from the cost of working the old service, and is given in Table VI.

Coal.—The coal consumed per ton-mile in the steam generating plant, pending the completion of the hydraulic power-house, will probably be not much less than that used on a steam locomotive if the speed and rolling-stock is the same in both cases. Thus, as the weight of the electric trains is about half that of the old steam train, the coal used per train mile will be halved. Possibly this assumption does not do justice to the economy of the electric system, but there is not sufficient data available to warrant a more favourable estimate being made. The speed is, however, nearly double, so that if the same rolling-stock

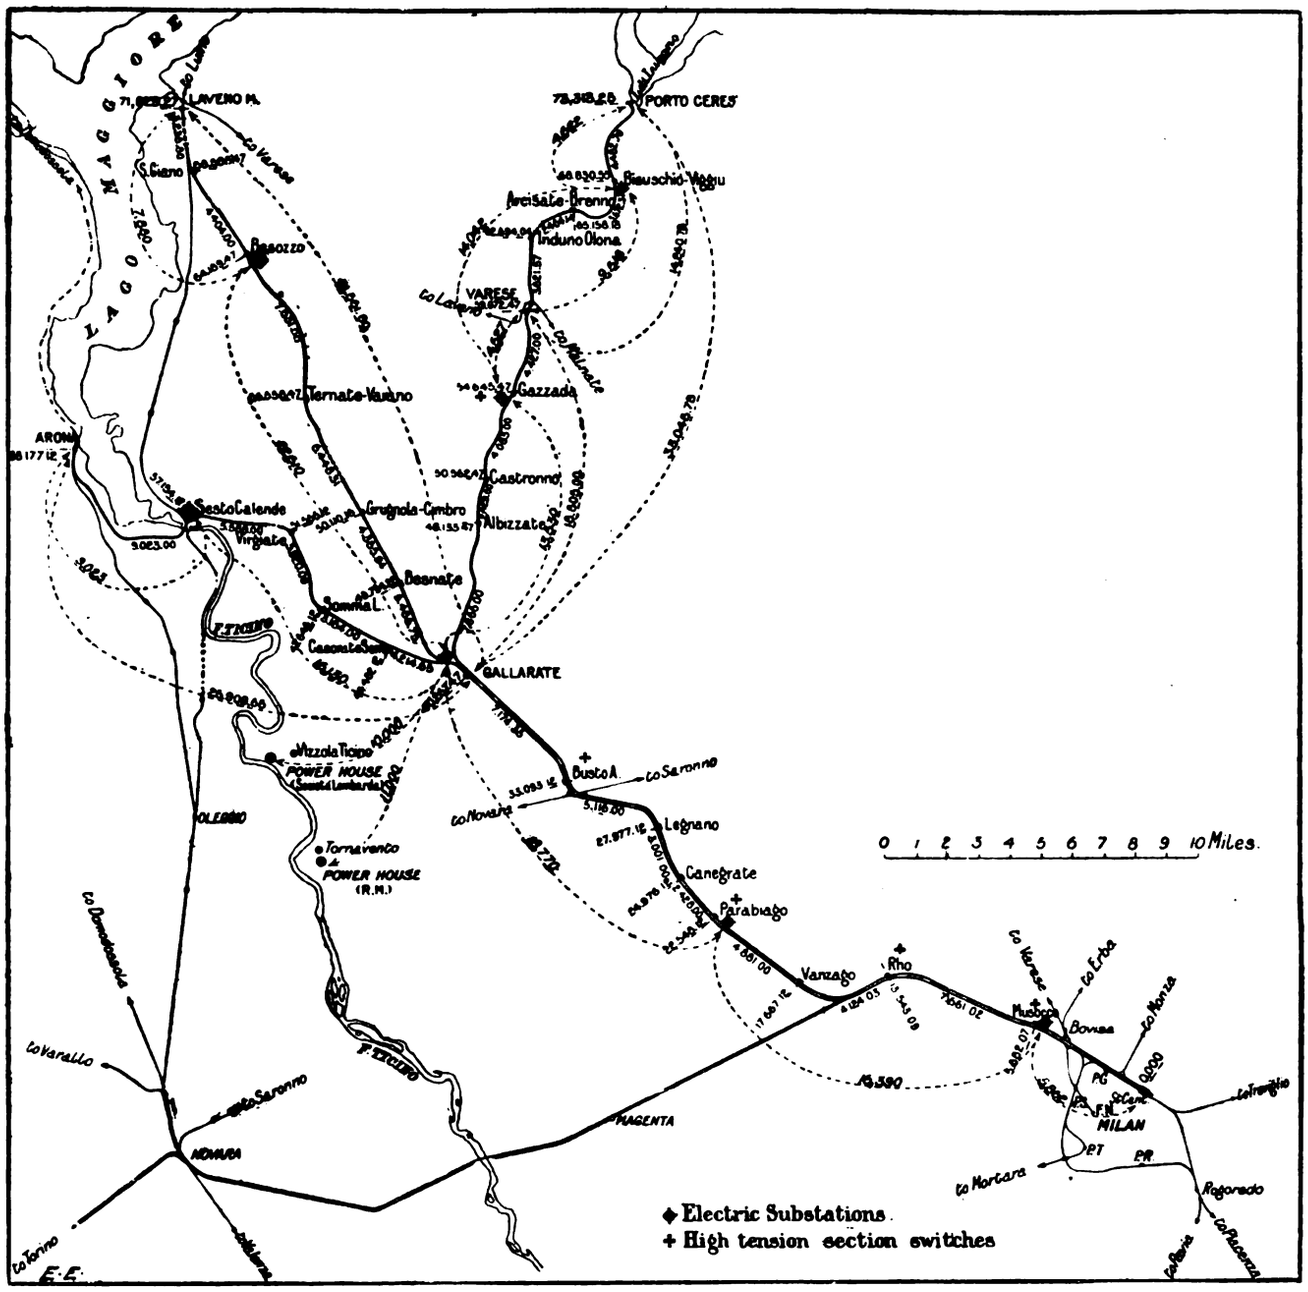

Fig. 3.

grades, which are as much as 2 per cent., and the trains will run with the motors in permanent series connection.

Table V.—Giving the Steam and Electric Train Service on the Milan-Varese Railway.

—	Miles	Max. grade.	Min. curve chains.	Trains each way per day.		Time in minutes.	
		Per cent.		Steam	Elect.	Steam	Elect.
Milan to Gallarate	25·0	0·6	40	10	35	60	34
Gallarate to Varese	11·7	1·0	25	7	27	28	18
Gallarate to Laveno	19·4	0·8	30	6	8	81	50
Gallarate to Arona	16·0	1·1	17·5	5	8	45	45
Varese to Porto Ceresio..... ...	8·8	2·0	15	5	6	28	28

were used, the tractive resistance, and hence the coal consumption, would be increased. But the type of rolling-stock is being improved, and short two-axle carriages are being replaced by long coaches running on bogies so that the tractive resistance at the higher speed should not exceed that at the lower speed by more than 25 per cent., bringing the coal consumption to 23lb. and the cost to 3·4d. per train mile. (Note.—The author learns from Signor Tremontani, the engineer of the Mediterranean Railway, that the coal consumption for a service of trains consisting of one motorcar and two trailers is 28·5lb. per train mile. The weight of these trains is one-third greater than that estimated in the paper, as it was found necessary to add a second trailer on account of the increase in the traffic. This increase in the weight of the train would have brought the author's figure for coal consumption up to 31lb. per train mile; his estimate, therefore, appears to be about 10 per cent. too high. At the present time only 20 trains per day are running each way between Milan and Gallarate, and 17 between Gallarate and Varese.

Wages.—The driver and fireman are replaced by one motorman at about half their combined wages, and as the electric train is always

Digitized by Google

ready to start up, a further saving of about 20 per cent. should be effected in comparison with a train hauled by a steam locomotive, which has to spend a considerable time in the shed. These savings should reduce the item for locomotive wages to 40 per cent. of its former value—that is, to 1·27d. per train mile. The item for conductors' wages will be reduced 20 per cent., owing to the saving of time mentioned above, and will be 1·67d. per train mile. The wages at the generating station will amount to about £4,000 per annum; for a line 80 miles long, and with 28 trains per day each way, the cost would come to 0·58d. per train mile. The wages at seven rotary sub-stations should not, together, exceed the wages at the generating station, making the cost for this item 0·58d. per train mile.

Water, Oil, etc.—The cost of water, which is 25 per cent. of that for water and oil combined, will be saved, reducing this item to 0·45d.

Repairs.—The cost of repairs will be reduced. On the City and South London Railway during 1901 the cost of locomotive and generating repairs per train mile, including wages and materials, was 38 per cent. of the locomotive repairs on the Great Northern Railway. Taking 50 per cent. of the cost of steam locomotive repairs, the cost of repairs for electric motors and generating stations would amount to 1·76d. per train mile. As the electric trains are one-half the length of the steam trains, the carriage repairs per train mile will

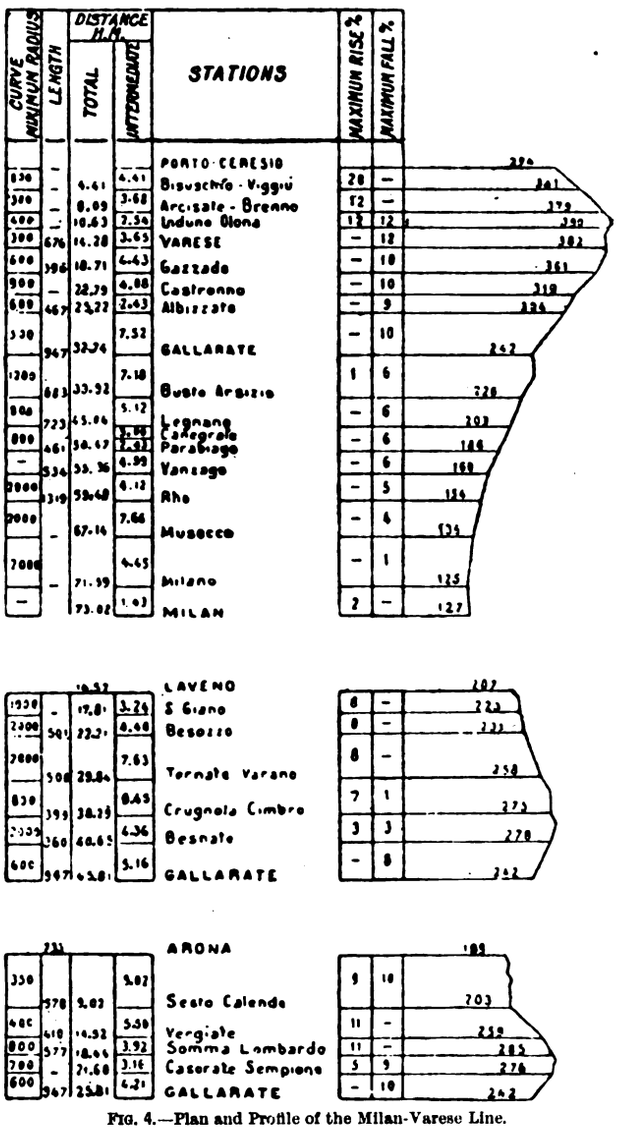

FIG. 4.—Plan and Profile of the Milan-Varese Line.

be halved; this item will thus be reduced to 3d. per train mile. The total cost of running would thus be reduced from 21d. to 12d. per train mile.

ESTIMATE OF TRAFFIC.

The passenger traffic required to pay the expenses of the new electric service can now be estimated. On the Milan-Gallarate-Varese line the service is being increased from 8 to 28 trains per day, while the cost of running is reduced from 21d. to 12d. per train mile. The cost per mile of line is thus increased from £510 to £1,110 per annum. To this must be added the interest on the capital expended in the electric installation. The total estimated cost is 10,000,000 francs, or £5,000 per mile. At 3½ per cent. this would add £175 per mile to the increased cost of running, making the total increase £775 per mile per annum. (See Table VII.) The passenger receipts for this line, including the extensions to Arona and to Laveno, are £600 per mile per annum. Hence the passenger traffic must be increased by 129 per cent. to pay the interest and the increased cost of running. With transformer sub-stations the running expenses are decreased 5 per cent., and the increase of traffic must then be 114 per cent. On the completion of the hydraulic power station coal will no longer be used, and this item in the cost of running will be saved. The cost per train mile will then be reduced to 9·31d., or, say, to 9·5d., making the total increase in the expenses £475 per mile per annum, and the increase in the passenger traffic required to meet this increase 80 per cent., as compared with 129 per cent. for steam plant. With transformer sub-stations the increase need only be 72 per cent. The value of water power may therefore be represented by a reduction of 20 per cent. in the passenger traffic required to pay expenses.

TABLE VI. Showing the Comparative Cost of Running an Electric and a Steam Line in Italy and in England in Pence per Train Mile.

Interest	—	175	175	—	280
Total	£510	£1,285	£985	£320	£960
Increase	—	775	475	—	640
Per cent. increase in traffic required to pay expenses	—	129	80	—	61

* With rotary sub-stations.

On the Lecco line the service of steam trains was formerly about half as frequent as on the Varese line. The proportional increase in the number of electric train miles will be about the same, so that the increase in the cost of running per mile of line, with transformer sub-stations, will be £150 per annum with water power. The capital expenditure has been about eight million francs, or £5,000 per mile, involving an interest charge of £175 per annum, which, together with the increase in the running expenses, brings the total increase to £325 per annum. The passenger receipts are here much less than on the Varese line, being £380 per mile per annum for the section Lecco-Colico, £220 for the section Colico-Sondrio-Chiavenna, and £330 per mile for the whole line. Thus an increase of £325 per annum will require an increase in the passenger traffic receipts of 128 per cent. The conditions of working an electric service on this line are therefore not quite so favourable as on the Varese line.

REDUCTION OF FARES.

The extent to which a combination of reduced fares and increased travelling facilities augment traffic has long been made a subject of careful consideration by the Italian railway companies. For some time past the Adriatica Company has been investigating this question experimentally on the line connecting Bologna with St. Felice, referred to above. The experiment was made with cars driven by electric accumulators. The speed and the frequency of the trains were both doubled, and the fares reduced to 40 per cent. of their original amount. The result has been that the passenger traffic has increased five-fold, and the receipts have been doubled. The fares on the new electric trains are given in Table IV., and are good for all trains whether express or omnibus. On the Milan-Varese line the reduced rates, as given in column C, have been available on omnibus trains only, express fares being charged on all express trains; about 20 per cent. of the total passenger receipts on this line being at the express rate, and 90 per cent. of the receipts from third-class passengers. If this proportion is maintained under the new conditions, the falling off in the receipts due to the reduction in the fares would be about 20 per cent., if there were no increase in the traffic. It has already been shown that to pay the expenses of the new service at the old rates the traffic must be increased 80 per cent. if water power is used, so that with the new rates the traffic must be rather more than doubled. With the new electric service on the Milan-Varese line the minimum fare is still about the same as before—namely, ½d. a mile—but whereas formerly this rate only entitled a passenger to travel on an omnibus train, it now entitles him to travel by any of the express trains, the speed of these trains being twice what it was before, and the service three to four times as frequent, so that for those who formerly patronised the express trains the fares have been halved and the speed doubled. The speed of the omnibus trains is also doubled, but owing to the number of stops the

Digitized by Google

saving in time is not more than 30 per cent. The new service has been inaugurated by the railway company in confident expectation that the improved service will increase the amount of traffic to such an extent that the receipts, even at the lower rates, will more than pay the expenses.

Comparison of the Conditions of Running an Electric Service in England and in Italy.

It may be useful to compare the figures obtained above for the conversion of a steam to an electrically-driven railway in Italy with those that would be obtained under similar conditions in England. If the reduction in the weight of the train and the increase in the service are in the same proportion in the two cases, the proportionate reduction in the running expenses will also be the same. With this assumption the cost will be reduced from 13d. to 8d. per train mile; the different items are given in Table VI. With a similar increase in the train service—namely, from 8 to 28 trains each way per day—the working expenses would be £680 per mile per annum, as compared with £320 with the former steam service, or an increase of £360 per mile. The electric installation would probably be more costly than that for the Italian lines, and might come to £8,000 per mile, on which the interest at 3½ per cent. would amount to £280 per mile per annum. The total increase in the expenses would thus be £640 per mile per annum. The passenger receipts for 1900 for the Great Northern Railway, to take a definite case, averaged 43d. per train mile, at which figure the receipts on a line running eight trains each way per day would amount to £1,050 per mile per annum: the average for the whole of the Great Northern Railway being £2,460. Hence, to make up for the increased cost of the electric service, the passenger traffic on such a line would have to increase 61 per cent., if the fares were unaltered. With halfpenny fares the traffic would have to be trebled.

It seems clear that, whether in England or in Italy, the full advantages of electrical traction cannot be obtained without an increase in the total running expenses, and this increase can only be met by a corresponding increase in the passenger traffic, so that the change from steam to electricity should not be made unless the increase in traffic may be reasonably expected at least to cover the increased cost of running and the interest on the capital expenditure. Most railway managers would probably admit that the use of electricity on existing railways is worthy of consideration, and some will even go so far as to say, "if you can show that we should reduce our expenses by adopting electricity, we would do so." It is not, however, by reducing expenses that electricity is going to help the railways, but in enabling them to offer greatly increased travelling facilities to the public at a figure impossible with steam traction, and thus to meet the growing competition of the tramways.

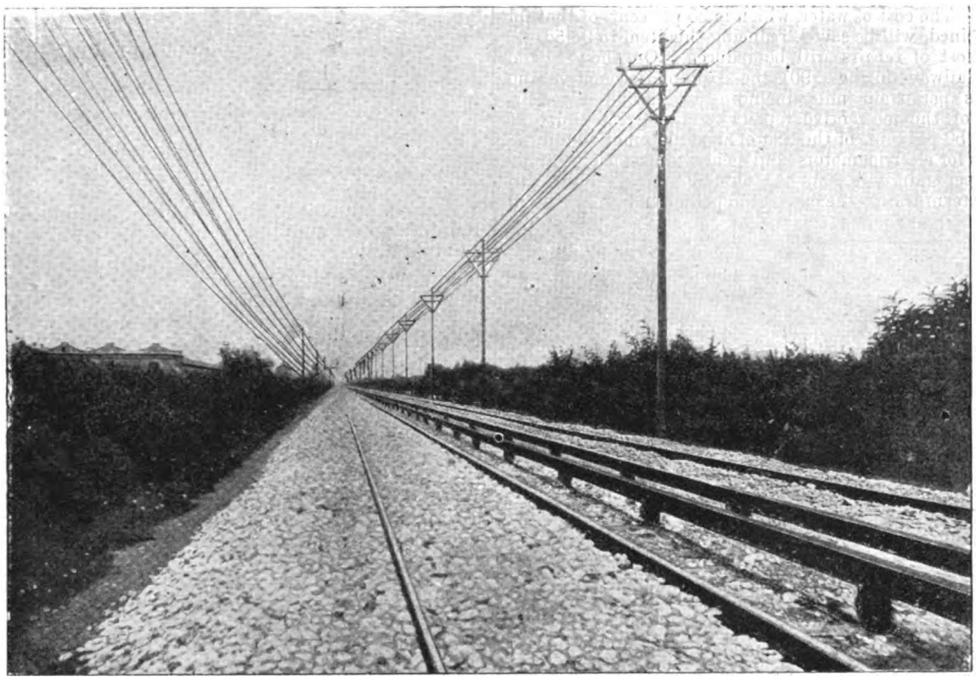

Fig. 5.—View of High-Tension and Third-Rail Construction on the Milan-Varese Line.

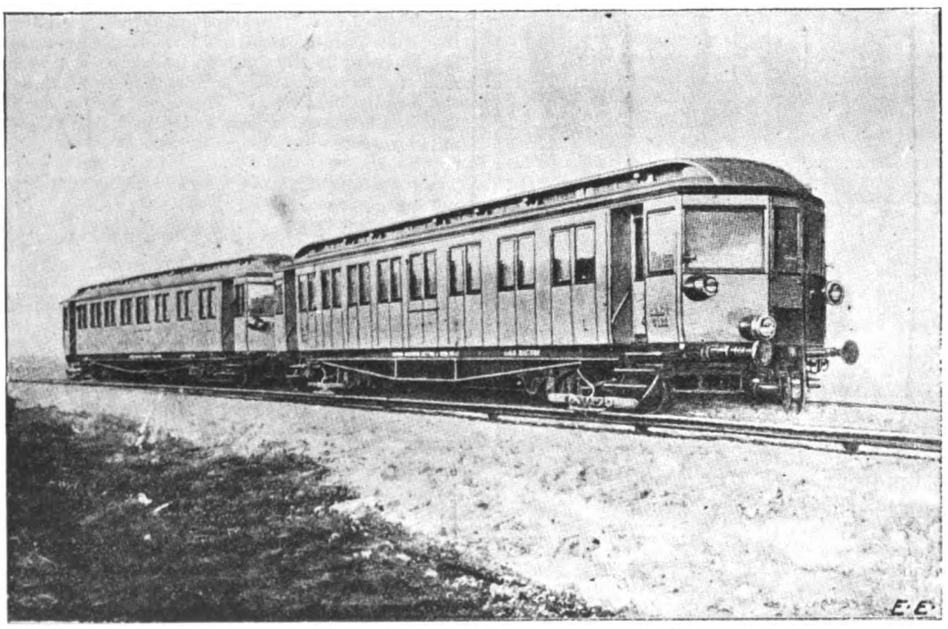

Fig. 6.—Motor Car Train used on the Milan-Varese Line.

In answer to the question as to why the Italian railway companies are adopting electrical traction, it is often urged that they are doing so because of the saving effected by the use of water power in place of coal. This is, however, very far from being the case, since even with water power the expenses cannot be met unless the traffic increases. The use of water power simply reduces the increase required to pay, the reduction in the case of the Italian lines being 20 per cent. The prospects of success in England with cheap coal are more favourable than they are in Italy with water power, as is shown by the fact that the increase in the traffic required to pay expenses is less in England than in Italy.

Digitized by Google

The figures given above do not take any account of the relative possibilities of travel development in the two countries. Milan has a population of 471,000, about equal to that of Birmingham, but the towns along the line now being electrified are all quite small, Gallarate having a population of 8,000, Varese of 6,000, and Arona of 4,000, the largest being Busto Arsizio with 13,000. Taking the different lines radiating from Birmingham, by way of comparison, we find that the united populations of the two largest towns on each line within a radius of 45 miles amount to 39, 41, 63, 86, 101, 109, 121, and 185 thousand. With these figures before one, it is difficult to avoid the conclusion that the possible increase in travel is far greater in England than in Italy, and that if there is a field of usefulness for electrical traction on Italian steam railways, there is a still greater field of usefulness on the railways of our own country.

I wish to express my thanks to the officials of the Strade Ferrate del Mediterraneo, and of the Strade Ferrate Meridionli, and in particular to Signor Ing. Victor Tremontani, Signor Ing. Pietro Lanino, and Signor Ing. Leone Olper for their kind assistance in furnishing me with data and information. I am also indebted to Signor Tremontani for the views and plans in Figs. 3, 5, and 6, and to Messrs. Ganz and Co. for the view in Fig. 2. In preparing the maps and profiles the following have been consulted: the map of Italian railways published by the Instituto Geograpico Militaire, and the official train sheets of the Adriatica Railway Company.

Discussion.

The **President,** in opening the discussion on the above paper, said they were all very much indebted to Prof. C. Wilson for his admirable contribution. It seemed to come at a most opportune time, having regard to the proposed visit of the Institution next spring to Italy, and he was sure it would act as an inducement to many to join in the tour. Prof. Wilson had done the railway companies of this kingdom a service in dealing with this question as he had more from the commercial point of view. It was simply the commercial aspect of the subject that would affect our English railway companies. If it could be shown that by the introduction of electricity advantage was to be obtained either in the economising of expenses or by increasing the receipts, then railway companies would be equally anxious with electrical engineers to adopt electric traction. But he was afraid that many, after reading Prof. Wilson's paper, might feel inclined to doubt whether such would be the case, because the author came to the conclusion that railway companies had to look not to economies so much as to increased traffic in order to make electricity pay. He (the president) very much questioned that with respect to British railways, and he was not in harmony with the author in his deductions, because it appeared to him from the tables and figures given in the paper that there was not a fair comparison between the railways in Italy and British railways. The latter were, of course, very much more costly, because the work was carried out in a much more perfect and complete manner. The position was this, that on British railways they had a very much larger traffic, and the lines were more full with trains than on Italian railways; and he thought that if they could only make a more complete comparison of expenses on English lines and Italian lines, they would see that such comparison did not quite support the conclusion to which the author had come. With reference particularly to the introduction of electricity on railways in Italy, he was glad to see that the companies were not adopting extravagant speeds, and he thought it would be far better for railways to consider what was a moderate speed than attempt very high speeds. In conclusion, he felt quite sure that if increased facilities would increase traffic on Italian lines, as they apparently had done, such increased facilities on British railways would be attended with far better results.

Mr. C. Steel, of the Great Northern Railway, said he was bound almost to endorse the chairman's remarks in preference to the observations of Prof. Wilson. The conditions of railway working in Italy and the character of the traffic were widely different from what they were in England. The introduction of an electrical railway, upon which were run trains consisting of few vehicles, could only be accomplished with success where there was a huge population to work upon. Taking, for instance, one of the lines to which Prof. Wilson had referred between Milan and some country town, there was not a large oscillating traffic. He maintained that it did not follow as a matter of necessity that because they had a quick service they would create traffic. Referring to Table VII. in the paper, the author had shown the expenses of running eight trains a day as compared with running 28 trains, and the expenses were given at £320 per mile per annum in the case of steam and £960 in the case of electric trains. The eight trains consisted of, say, eight vehicles each, and the 28 trains of two vehicles each, but the expenses were three times as heavy with the 28 trains and 56 vehicles as with the eight trains and 64 vehicles. Therefore, they were increasing their expenses enormously and not increasing their traffic. That brought him back to the point that one must consider the character of the traffic in dealing with the electrical question. Again trains of two vehicles were not adapted to dealing with London traffic, for instance. There was another matter to which Prof. Wilson had not referred in connection with the adoption of electricity on railways in this country—*i.e.*, trains could not be run at short intervals with crowded lines. This was one of the greatest difficulties with which the English railway companies had to contend with respect to this particular question, and another was that they could not reduce the fixed expenses as they did in Italy. His own feeling was that, so far as English railways were concerned, there was not much hope of their electrification—certainly not in the suburbs of London—but in any case electricity could only be used profitably on railways which were strictly passenger lines. Assuming that they could not introduce electricity on existing railways, the alternative was to provide additional lines, and the cost of doing this in London would be simply prohibitive. He was sure that railway directors would be very slow at this time of day to adopt any system which increased the working expenses and left the question of increased traffic as a problem to be solved in the future. He felt, however, that there was a need for electrical lines in this country, and he hoped that the difficulties in the way of electricity at present would be overcome in the near future.

Mr. H. M. Sayers observed that it did not appear from the previous speaker's remarks that our main lines could do anything in the way of electrification, and, he supposed, Mr. Steel was content to be left with his coal trucks and mineral traffic, because that was what it would come to. On the question of increased facilities creating traffic, he pointed to the case of the electric tramways in this country. In one instance which he quoted, a steam tramway in England used to carry an average of 1,800,000 passengers per annum, but in the first year after the lines were electrified this figure increased to six millions, with only a short extension of the lines. The greater facilities offered consisted of a more frequent service, a higher speed, lower fares, and smaller carrying capacity. He argued from this that even on main lines, if greater facilities were offered, passenger traffic would increase.

Mr. W. R. Cooper expressed the opinion that in some instances the figures given by the author for steam and electric working did not offer a fair comparison. Then, some of the conclusions given at the end of the paper were rather misleading as they stood. They amounted to saying that there must always be an increase in traffic for electric traction to pay, and that conclusion was arrived at by assuming an increase in the number of trains run. Of course, if they increased the number of trains run they must increase the traffic in order to make a profit. As to competition of tramways, the main lines in this country would not be affected as they were in Italy—where the main-line trains were run at slow speed and stopped at practically every station for about five minutes. So that they could not compare the main lines of this country with those of Italy. What they wanted to find out was the true comparison between electrical and steam traction with the speeds they had at present. Then it was not really a question of increasing the traffic. That applied to local lines, but not to main lines. He suggested that, in making such a comparison, it would be as well to take into consideration the goods and mineral traffic, which involved difficulties of shunting and sidings. The importance of considering this class of traffic might be gathered from the fact that the coal used per train mile on a passenger locomotive was 36lb., as against 62lb. in the case of a goods engine.

Mr. Arnold Lupton was inclined to think that the economy of fuel with electricity would be even greater than stated by Prof. Wilson in his comparisons of steam and electric railways. With the introduction of gas engines in the generating stations the charges on account of fuel would be even further reduced. He agreed that in country districts electric traction on the railways might create traffic. In those districts it was often a whole day's work to go 20 miles to a market town and back again, on account of the bad service of trains and the delay at junctions. With regard to the item given by the author of interest on cost of installing electric traction, he pointed out that this would not come in as an additional expense in the case of new lines, but only where steam lines were converted.

Major-General Webber suggested that the discussion at this point should be carried over to the first meeting of next session, as the subject was one of immense importance. Such a set of tables as had been brought before them by Prof. Wilson should be subjected to all the light that experience could give. Therefore, he hoped that this meeting would agree to the adjournment of the discussion as he proposed, and between this and next session the members would have time to think over the subject, which might probably result in giving them one or two most interesting and instructive evenings next session.

The **President** thought it would be unfair to the author if they carried over the paper in the ordinary sense of the word until next session, because Prof. Wilson would naturally like to have it published. He would, therefore, ask the author to reply to the discussion which had proceeded so far, and to supplement the paper by some further information between this and next November. That arrangement, he thought, would answer the purpose equally as well.

Prof. Carus-Wilson, in the course of his reply, remarked that it often happened that the discussion on a paper did not follow on the same lines as the paper itself, and thus the main points of the subject which the author desired to bring forward for discussion were not always taken up by the speakers. In this case it might be supposed that he was advocating the introduction of electricity on main lines. He assured them, however, that nothing was further from his intention. The railways dealt with in this paper were defined by the number of trains run, and he did not think anyone would say that a service of eight trains a day was a main-line service. Therefore, he could at once offer a reply to their criticism that the general drift of the statements in the paper offered no fair comparison between the state of affairs in Italy and that in this country. What they had to do was to compare line for line, and take a line in Italy being electrified and compare it with a line carrying the same amount of traffic in this country. Mr. Steel's remarks, of course, came with very great force from one who had for so long carried on the very responsible duties of the managership of one of our greatest railways. But there was really no difference between his views on this subject and the views expressed in the paper. Mr. Steel had, in fact, put forward in the clearest way the position he (Prof. Wilson) wished to take up—that was to say, that the introduction of electricity on lines (other than suburban) which were at all comparable with those now being electrified in Italy, depended entirely on an increase of traffic. He firmly believed that it was only by looking forward to the increased facilities for developing traffic that electricity would ever be introduced on lines such as these. Mr. Cooper in his remarks had said that it was unfair to consider simply the case where the train service was increased with the introduction of electricity, and that they should include also the case

Digitized by Google

where the train service was the same as with steam. He thought that there again Mr. Cooper had struck the fundamental point of difference between the way to look at this whole question. The great advantage of electricity was that they could increase the frequency and the speed of the service, and it was only when they could do that that it was worth while to make the change. Mr. Lupton thought he had made the cost of fuel too high. While he hoped it might be too high, he had endeavoured to be conservative in the statements he had made in the paper. As to the question whether the cost of electrifying a line would be different if the line were constructed *de novo*, he had not gone into that matter, but had simply taken the case of the electrification of existing steam lines. He commended the concluding two pages of the paper to the attention of members who wanted to clearly understand his position. He had endeavoured to find out while in Italy what were the possibilities of traffic on the electrified lines, and when one took the population round the Varese line and compared it with our own lines, he thought there was no doubt that the possibilities of increase of traffic in this country were far greater than in Italy. He might also say that the railway companies in Italy had not approached this problem of increase of traffic in a policy of blind faith. They were electrifying their railways as an outcome of most careful study of this question, and he thought that was what the managers of our great lines ought to do now. He suggested that they should lose no time in taking steps to inform themselves on this very vital question, for, as far as he could find out, very little was known in England outside experienced people as to what was the precise connection between increased facilities and increase of traffic. He thought that if railway managers studied this matter, they would become very much more hopeful of the travelling potentialities of the British public.

A hearty vote of thanks was accorded the author for his paper.

BOLTON ELECTRICITY ACCOUNTS.

The accounts of the Bolton Corporation electricity department to March 31, 1902, show a total expenditure on capital account of £180,258, of which £21,208 has been written off for depreciation. Abstracts of the revenue account, balance-sheet, and statement of electricity generated, sold, etc., are appended:

NOTES.

Students' Awards.—We are informed that the following awards to students have been made by the Council of the Institution of Electrical Engineers: the Salomons Scholarship, value £50, for 1902, to Mr. Philip A. Laubach; the David Hughes Scholarship, value £50, for 1902, to Mr. Edward Fisher (both of Finsbury Technical College); and the following premiums: Mr. Fielder J. Hiss, jun., £7; Mr. Philip A. Laubach, £5; Mr. E. W. Short, £5; Mr. S. E. Glendenning, £3.

Electro-Harmonic Society.—The annual general meeting of the above society was held on Wednesday at the Institution of Electrical Engineers, 28, Victoria-street. The report of the hon. secretary, Mr. W. E. Lane, stated that during the past season 64 gentlemen have been elected members of the society and 32 old members have resigned. In the same period the society has lost two members by death, while four members have been struck off the register. The membership roll now contains 358 names.

Royal Institution.—A general monthly meeting of the members of the Royal Institution was held on the afternoon of the 2nd inst., the Duke of Northumberland, president, in the chair. Mr. J. Christie, Mr. F. K. McClean, and Sir John Denison Pender were elected members. We are informed that, owing to the presence of Royalty, it will be necessary to reserve the whole of the available seats in the lecture theatre for the special use of members at the discourse to-night by Sir Benjamin Baker on the subject of "The Nile Reservoirs and Dams."

"Science Abstracts."—We are informed that the following journals have been added since the beginning of 1902 to the list regularly dealt with in *Science Abstracts*, making a total at present of about 150: *Journal* of the Russian Physico-Chemical Society; *Proceedings* of Academy of Sciences at Amsterdam, at Stockholm, at Christiania, and at Copenhagen; also *Zeitschrift für Anorganische Chemie*; *Royal Society of Edinburgh Transactions*; *British Optical Journal*; *Elettricista* (Rome); *Iron and Steel Institute Transactions*; *American Society of Mechanical Engineers' Transactions*; *Engineering and Mining Journal* (New York); *Power* (New York); *American Telephone Journal*; *La France Automobile*; *Der Moterwagen*; *Archives of the Rïntgen Ray.*

Boilers for the Navy.—Official announcement is made that the Admiralty have decided on the following types of boilers for the six first-class cruisers included in the 1901-2 programme and now under construction. The "Devonshire" and the "Carnarvon" will both have a combination of four-fifths Niclausse and one-fifth cylindrical boilers; and the "Hampshire" and the "Antrim" a combination of four-fifths Yarrow and one-fifth cylindrical boilers; the "Roxburgh" is to be equipped with a combination of four-fifths Dürr and one fifth cylindrical boilers; and the sixth vessel, the "Argyll," will use a combination of four-fifths Babcock and Wilcox and one-fifth cylindrical boilers.

Telephone Communication with Lighthouses.—A question put in the House of Commons the other day by Mr. Soares, M.P., with reference to the advisability of setting up telephonic communication with Braunton lighthouse, in North Devon, has elicited an encouraging answer from Mr. Gerald Balfour. The Postmaster-General, he said, was of opinion that, *prima facie*, the proposed connection by telephone was desirable, and the matter is to be submitted to the committee on electrical communications with lighthouse stations for their consideration. It appears, however, that the work cannot in any case be carried out immediately, as the whole of the funds provided by the Post Office for extension of coast communication during the current financial year have already been allotted.

The Deputation to Mr. Balfour.—The secretary of the Institution of Electrical Engineers informs us that Mr. Gerald Balfour, the President of the Board of Trade, has again found it necessary, on account of urgent public business, to postpone his reception of the deputation which has been appointed to wait upon him on the subject of electrical enterprise. The interview was fixed for yesterday at 12 noon, but under the circumstances it has been postponed indefinitely. Mr. Balfour, however, has the matter before him, and will shortly fix another date for receiving the deputation. As already stated, the object of the deputation is to lay the views of the Institution before the President of the Board of Trade with reference to the legislation at present controlling electrical enterprise in this country, the general feeling being that the industry is unduly hampered by over-legislation.

Electric Lighting in East London.—In reference to our note last week under this heading giving the result of the Board of Trade arbitration into the price to be paid by the three districts of Mile End Old Town, Limehouse, and St. George's-in-the East for the electric lighting provisional order held by the County of London and Brush Provincial Electric Lighting Company, that company now inform us that the arbitrator's total award amounted to £6,893. 5s. 4d., made up as follows: cost of preparing, obtaining, and passing the County of London (East) Electric Lighting Order, 1897, £710. 6s. 7d.; costs properly incurred by the company with the object of supply to the East-end districts, £5,814. 13s. 11d.; and costs of the award, £368. 4s. 10d. The arbitrator also made an order for one-half of the company's costs of the arbitration, to be paid by the local authorities concerned.

Tunbridge Wells Telephones.—We have much pleasure in being able to congratulate the Corporation of Tunbridge Wells and Mr. A. R. Bennett, their consulting engineer, on having obtained the sanction of the Local Government Board to the expenditure of a further £15,000 on the municipal telephone system. It will be remembered that at the official enquiry into the matter a short time ago the Corporation had to contend with the most hostile opposition on the part of the National Telephone Company, and the decision of the Local Government Board to sanction the loan has, therefore, given the greatest satisfaction among supporters of the municipal system in the town. That the money in question is badly needed for extending the Corporation lines, may be gathered from the fact that the subscribers to the municipal exchange have increased by as many again in the past six months.

Polyphase Traction.—A very interesting plant for polyphase traction at 3,000 volts has just been laid down at Neustadt, near Vienna, with the object of connecting the Government arsenal with the Schneeberg railway, some two-thirds of a mile apart. From information gathered from *L'Industrie Electrique*, it seems that the locomotive consists of a 36-kw. three-phase induction motor geared to the wheels and fed from two trolley wires, upon which the usual Continental bow trolleys are employed. The track is used as the third element of the circuit. The locomotive is provided with an air-compressor for brakes and also for the operation of the controller, which is indirectly handled with compressed air. The locomotive is said to greatly resemble those constructed by Ganz and Co. for the Valtellina railways in Italy. The line has now been in operation about three months, and has given the greatest satisfaction. It is considered to have demonstrated that

Digitized by Google

the use of 3,000 volts alternating on a trolley wire is relatively simple and easy and commercially economical.

Commutator Insulation. — A common trouble experienced with the ordinary form of commutator insulation, which consists almost invariably of mica, because of its good insulating qualities and its ability to resist high temperatures, is that the mica and the copper do not wear down at the same rate. The result is that after a considerable period of service the mica strips project slightly above the general level of the commutator segments, and cause the brushes to jump and spark. A method of correcting this trouble has been patented in the States by Messrs. E. D. Priest and G. L. Schermerhorn, which consists of using strips of some soft material, such as asbestos, between two strips of mica. According to our contemporary the *American Electrician*, the advantage of this construction is that the mica may be made very thin, so that it will break off readily as soon as it projects appreciably above the commutator segments, while asbestos, being soft, will wear away at least as rapidly as the commutator segments.

Post Office Telephones.—A return of Post Office telephone exchanges just completed shows that the total number of subscribers at the end of last year was 2,420, of which North Wales alone is responsible for 1,044. Newcastle heads the list with 437 subscribers, Cardiff comes second with 236, and Newport (Mon.) third with 132 subscribers. Liverpool and Manchester have 29 and 27 respectively, the same as Abergavenny and Bridgend. It is noticeable that in no part of the kingdom has the rate of increase and extension of lines been so great as in South Wales and the western valleys of Monmouthshire. The tariff does not differ greatly, though the use of the penny-in-the-slot machine is on the increase. The above figures, of course, do not include London subscribers, as they were abstracted from a report for a period ending before the metropolitan exchanges were opened. In connection with the movement for extending the telephone system in Mid-Wales a conference of delegates representing the towns of Welshpool, Montgomery, Newtown, Llanidloes, Machynlleth, Aberystwyth, and Towyn was held last week at Aberystwyth, when a resolution approving of the principle was unanimously passed.

Electric Elevators.—An interesting paper was read by Prof. G. Lever at a recent meeting of the American Institute on "The Power Consumption of Electric Elevators," the main object of which was to draw a comparison between direct-current and alternating-current motors for this class of service. Approximately, there are 3,000 elevators in New York operated by the former, and only 300 driven by alternating-current motors. The author gave the results of some 20 tests made on installations in New York, five of which were on direct-current machines and 15 on alternating-current machines. One conclusion drawn by Prof. Lever was that, with power at 5d. per horse-power hour, it is more economical to use direct-current motors for elevator work where both direct and alternating current are available. Other conclusions expressed were that if the controlling apparatus of the alternating-current motor is more simple, and the absence of commutator and brushes can be considered as an advantage, the extra expense for power required by an alternating-current machine might be offset by the decrease in repairs and attendance. Apart from these considerations, the direct-current motor has every advantage.

Conductivity of Liquid Dielectrics.—The current number of the *Journal* of the Chemical Society abstracts a paper by Mr. Curie on the conductivity of liquid dielectrics under the influence of radium or Röntgen radiations. It is shown that liquid dielectrics, like gases, acquire conductivity under the influence of radium, results of the same order of magnitude being obtained in the two cases. In the case of gases, the intensity of the current increases proportionally to the difference of potential between the electrodes when this difference is slight, but becomes almost constant when the difference is increased sufficiently. In the case of the liquids, however, the proportionality exists up to a potential difference of 450 volts. Of the liquids examined, carbon disulphide gave the greatest conductivity, which reaches 20×10^{-14} mhos per one cubic centimetre. Liquids which are ordinarily almost perfect non-conductors exhibit this effect, as, for example, liquid air, light petroleum, etc. The effect was exactly the same whether the radium was kept at the ordinary temperature or at the temperature of the liquid, from which it follows that the radiation from the radium does not vary with temperature between the limits of the ordinary temperature and that of liquid air.

Skin Effect in Electrical Oscillations.—A recent paper by Mr. C. A. Chant gives an account of elaborate experiments undertaken to find whether electrical oscillators with very thin surfaces of metal are as efficient as similar ones made solid or with thicker skins. Oscillators of the cylindrical and of the spherical type were used. The cylindrical oscillators were 2·5cm. in diameter and 12·5cm. long, the ends being hemispherical. The materials used were respectively solid brass, solid Norway iron, copper tubing 1·5mm. thick and 0·8mm. thick, solid electric light carbon, sheet platinum 0·0013cm. thick on a wooden form, sheet silver 0·002cm. thick, tinfoil 0·0025cm. thick on wood, gold leaf 0·0000114cm. thick on wood, silver leaf 0·00003cm. thick on wood, copper deposited electrolytically to thicknesses 0·0001, 0·00015, 0·0002, and 0·0005cm., silver deposited chemically on glass to a thickness of 0·000013cm. The spherical oscillators were of the Righi pattern. The oscillator spheres were of three sizes—viz., 2·5cm. in diameter, 4cm., and 10cm.; each size was made in solid brass and in gold leaf on wood. The receiver used was a Rutherford magnetic detector. The results given in tabular form show that, in the case of the cylindrical and spherical doublets, the various thin mantles and even the excessively thin gold-leaf shells were as efficient as the solid metal bodies.

E.M.F. of the Hydrogen Chlorine Element.—In a recent paper by Mr. E. Müller, abstracted in the current number of the *Journal* of the Chemical Society, the author describes an attempt to determine the E.M.F. of the above element in an apparatus similar to that used by Wilsmore. The electrolyte was hydrochloric acid solution, and the gases were continuously passed over the electrodes. The following values were obtained for the E.M.F. with the various concentrations of acid:

Normality of acid	1	1/10	1/100	1/1000
E.M.F.	1·3660	1·4849	1·5460	1·5868 volts

Assuming that N-hydrochloric acid is dissociated to the extent of 78 per cent., it is calculated that the electrolytic potential is 1·3532 volts. The observed values of the E.M.F. are not in agreement with those calculated, and it is shown that this is partly due to the hydrolysis of the chlorine which takes place, and this increases the concentration of the H· and Cl′. In N/10 solution of hydrochloric acid, the H· or Cl′ concentration rises from 91 to 94·03 millimols. per litre by this hydrolysis, in N/100 solution from 9·6 to 33·48, and in N/1000 solution from 0·98 to 30·48. With the aid of these concentration differences, the calculated values of the E.M.F. agree better with the observed values, but the deviations remain greater than the experimental error.

Digitized by Google

The origin of the chlorine (hydrochloric acid and dichromate, hydrochloric acid and pyrolusite, or electrolytic) has no influence on the E.M.F., and heating the gas in order to decompose chlorine peroxide is also without influence.

Electric Cable Specifications. — The important subject of the tests and specifications for electric cables was recently discussed before the Société Internationale des Electriciens of Paris, and the conclusions arrived at are published in the society's *Bulletin*. It seems that a committee were appointed to circularise a number of cable manufacturers and experts in order to elicit their views on the subject. The principal results of the enquiry may be shortly summarised as follows: In the first place it is recommended that electric cables should be subjected to a volt-resistance test of 100 per cent. pressure over and above that of full normal load, if the test be applied before laying, and 25 per cent. extra pressure after laying. Secondly, that the insulation resistance per kilometre should be adopted on the following sliding scale: 700 megohms for cables up to 1,000 volts normal working pressure; 3,000 megohms up to 4,000 volts; and 6,000 megohms up to 10,000 volts. In the course of the discussion before the Société Internationale a member criticised this sliding scale, suggesting that 500 megohms per mile would be sufficient for all pressures in normal use. In general, it would be better to adopt reliable means for preventing the occurrence of abnormal rise of pressure in a cable, than to spend much money upon so great a thickness of insulation as would withstand all the rise of pressure that could ever occur in it unchecked.

A Year's Patents.—The Comptroller-General of Patents, Designs, and Trade Marks has just issued his report for 1901—a year of considerable activity seeing that the number of applications under all heads is the largest since 1899. Thus last year there were 26,777 applications for patents, and of these 17,813 were from the United Kingdom, 601 from other parts of the British Empire, and 8,363 from foreign countries. Of these last 3,246 came from the United States and 2,844 from Germany, making together nearly 73 per cent. of the total number of foreign applications. Remarking on the trend of invention last year, the Comptroller-General says that during 1901 the attention of inventors was specially directed, as in 1900, to the subject of electric traction. The protection of the public from accidents due to broken wires was an object which occupied many minds. Motor-cars showed a considerable increase, especially as regards cars propelled by oil motors. The experimental trials of air-ships and submarine boats led to a number of applications for patents relating to these subjects. Among other applications, obviously suggested by various occurrences of the year, were cases for preventing vibration in "tube" railways and spark guards for locomotives. The increase in the applications relating to improvements in all classes of electrical apparatus, with the exception of galvanic batteries, is very striking, the total being the largest on record. It is interesting to see the difference between the number of applications for patents and the number that attain to full age. For instance, of 9,817 patents sealed in 1888, only 506, or 5·2 per cent., were maintained for the full period of 14 years by the payment of the annual recurring charges. The accounts showed total receipts amounting to £232,331, against which the total expenditure in the year was £125,040, leaving a clear surplus of £107,291.

Electricity in Mines.—In the House of Commons on Thursday week Mr. Markham asked the Secretary of State for the Home Department whether he would state the number of deaths that were directly due to the use of electricity in mines or shafts since May 2, 1901, and what course he purposed adopting to prevent this loss of life in view of the development of electric power in mines; whether, in view of the fact that Mr. A. H. Stokes, his Majesty's inspector of mines in the Midland district, in his report for the year 1901 states that in a mine in his district, owing to the short-circuiting of a cable, an explosion of gas occurred which would have resulted in loss of life if any men had been working in the mine at the time, he was aware that accidents were constantly occurring in mines from the short-circuiting of cables, causing in some instances fire in the mines, and that none of these accidents were reported to his department, except when an actual explosion or injury or loss of life occurred, and whether he had any power to insist upon colliery companies making a return of all such accidents. Mr. Ritchie, in reply, said he could give the number of deaths in mines due to the use of electricity in the year 1901. There were four deaths in all—two caused by electric shock, and two by machinery moved by electricity. All these accidents could be found described in the inspectors' reports. The use of electric power in mines was being carefully watched by the inspectors, and in due time he should be prepared to consider whether any steps ought to be taken with regard to it. He had no information as to the number of accidents caused by short-circuiting in mines, but the cases in which serious injury or loss of life had resulted had been very few. There was no power to require owners of collieries to report accidents caused by short-circuiting to the inspectors unless death or serious injury was caused or an explosion was produced; but a committee had been appointed by him to enquire into the general subject of the reporting of industrial accidents, and this and similar matters would, no doubt, be considered by them.

Australian Aluminium.—Although the discovery of aluminium dates only from 1828, it has long been recognised as one of the most useful and important of the minor metals, chiefly by reason of its extreme lightness, its weight being only one-fourth that of silver. This lightness has determined its use, among other things, in the construction of very delicate balances designed to register fractional weights It is obtained principally from bauxite, a mineral consisting chiefly of alumina, or oxide of aluminium and oxide of iron, which, until recently, was obtained principally from France. The existence of bauxite in New South Wales was not known until 1899, but almost simultaneously it was detected in extensive deposits in the Inverell and Emmaville districts, in the northern part of the State, and at Wingells, about a hundred miles south of Sydney. Its mode of occurrence is similar in both districts; it is frequently roughly stratified, and is generally found capping small hills, in many cases surrounding points of eruption. It is clearly of volcanic origin, and while in some cases it appears to consist of volcanic ash, in others it may have been derived from the decomposition of basalt *in situ*. In colour the New South Wales bauxite varies from pale yellow to deep red. Only the bauxite deposits near Emmaville have been officially mapped out as yet; nor has there been anything in the shape of a systematic examination of those whose existence in the State has so far been ascertained. At the present time aluminium is largely used for many purposes, and others are continually being discovered. In metallurgy, shipbuilding, and other directions the use of the metal is steadily increasing, and should its manufacture be started in New South Wales, where, according to Mr. John Plummer, of Sydney, bauxite is more abundant than generally supposed, a new and

Digitized by Google

profitable industry would become established. The ore could be conveyed by rail to places where coal is cheap and plentiful; also the materials for constructing smelters. Or the coal could be taken to the neighbourhood of the bauxite deposits. Either way there appears to be a good opening for those possessed of the necessary capital, experience, and energy.

Simple Forms of Resistance.—A German contemporary recently described two simple forms of adjustable resistance, one for dealing with fairly large currents, and another for small currents. The first of these is a metal resistance designed by Haber, and used by himself and Geipert in an experimental investigation relating to the electrolytic reduction of alumina. It is claimed that the use of this device avoids all danger of overheating and of fire. The apparatus consists of a large number of nickel tubes, placed parallel and joined at their ends to one another by U-shaped couplings. The end tubes are joined by rubber tubing to some water supply and to the waste-pipes. The gaps between the neighbouring tubes are provided with sliding bridge pieces of brass or nickel, which can be fastened by a thumbscrew in any desired position. When all the bridge pieces are at the top end of the resistance, the whole of the current passes direct to the apparatus through the heavy couplings and the bridges, whereas when all the bridge pieces are at the bottom of the resistance, practically the entire length of the nickel tubing has to be traversed by the current. By adjusting the various bridge pieces the current can be regulated within very close limits, and as the nickel tubes are kept cold by the constant flow of the water through them, the trouble caused by the variations due to heating in the ordinary forms of resistance is said to be avoided. The second form of resistance is of the liquid type. The U-tube, in which the resistance liquid is contained, is formed with enlargements at its upper ends, and is provided with an elongation at the bottom of one leg, and an escape cock. The mouth of one leg is covered with a flat cork disc, and through this a glass rod slides easily. The electrodes are fused in the glass. The variation in the resistance is effected by sliding the glass rod up and down in the tube containing the electrode. As shown in the diagram accompanying the description of the device, the rod nearly fills the narrower part of this tube, and only a very thin body of liquid is then present by which the current can travel. By using a modified form of the apparatus with two additional legs containing sliding rods, and with electrodes connected in parallel, it is claimed to be possible to regulate the current within very wide limits.

Mercury Cathode Cells.—Mr. C. P. Townsend, in an article published by the *Electrical World*, describes two recent improvements in the production of chlorine and caustic alkali by the mercury cathode process. Both improvements relate to the form of the cell and to a peculiar arrangement of several cells in series, whereby is assured the presence of a sufficient quantity of sodium in the mercury to prevent oxidation of the latter metal in the caustic compartments. In the first form of construction of the new cell the controlling idea is the distribution of the mercury in both compartments in a thin film over metal plates or discs. The carbon anodes are immersed in sodium chloride solution in a cell, sealed at the bottom by mercury in open troughs, and at the top by a cover with depending flanges. The cathodes, which may be grooved discs of copper, are rotatably mounted on the shaft, and dip into mercury contained in a series of transverse troughs communicating with the lateral troughs. By the rotation of the cathode discs the mercury is taken up by the groove, distributed evenly over the surface of the discs, there becoming charged with alkali metal, and the resulting amalgam is collected by the mercury in the troughs. This amalgam then flows through troughs to the oxidising cell, there to function as anode and be denuded of its alkali metal. In this cell the mercury acts as a bipolar electrode, constituting the cathode in the decomposing compartment and the anode in the oxidising or caustic cell. If, however, the entire current passing to the mercury as cathode passes also from it as anode, some danger is incurred of oxidising the mercury as well as the sodium. The second improvement above referred to aims at getting rid of this difficulty by the series arrangement of the cells. The direct connection through the mercury is broken at four points by transfer devices, and the current carried around the gaps by circuit. It follows, therefore, that the four cells are decomposing cells, in which the amalgam is produced, whereas in two of the cells the amalgam functions as anode and the oxidation of the sodium to caustic occurs. Since all the cells are connected in series, and since the number of decomposing cells is in excess of the number of oxidising cells, it is clear that an excess of sodium above that required for carrying the current is ensured, and that no oxidation of the mercury can occur. Both improvements are the inventions of Mr. Chas. J. Reed, who, we understand from our contemporary, has taken out patents in the States for their protection.

City and Guilds of London Institute.—The annual meeting of the City and Guilds of London Institute was held at Mercers' Hall, Cheapside, on Wednesday week, under the presidency of the Lord Chancellor. Conspicuous among those supporting the chair was Lord Kelvin, who has recently returned from a visit to the States. The report of the Dean of the Central Technical College (Mr. O. Henrici) stated that the Clothworkers' Scholarship was this year awarded to Mr. J. A. Esnouf, who was educated at the Royal College, Mauritius, and who holds a scholarship of £200 a year from that school. The Siemens Memorial Scholarship was awarded to Mr. W. E. G. Bender, the youngest of the candidates, being under 16 years of age. The three institute's scholarships were gained by Mr. V. B. Hurley Mason, Mr. T. F. Lee, and Mr. C. D. McCourt. The Siemens medals were adjudged to Mr. J. J. Fasola for electrical engineering (to which a premium is added) and Mr. J. D. W. Ball for civil and mechanical engineering. An interesting paragraph in the report is the announcement that, in order to give the engineering students an opportunity of more extended practical surveying work, a fortnight's trip to Mersea Island in Essex was made in the summer vacation. In regard to the report of Prof. Silvanus Thompson on the work of the Finsbury College in the past year, it is noteworthy that the electrical department is again the largest, having 92 entries against 49 in the mechanical department and 46 in the chemical department. A good deal has been done during the present spring to reorganise many of the experiments in the elementary part of the college, but as yet nothing has been attempted in the way of renewing the dynamos, all of which are of types now obsolete. Towards the end of his report Prof. Thompson stated that the demand from employers for students capable of undertaking electrical work in one or other branch has exceeded all previous experience. The Brush Electrical Engineering Company's free pupilship has been awarded to Mr. T. A. Davies, who will join that company's staff in November. The Lord Chancellor, speaking on the above reports, referred to the offer of the London University to devote a substantial sum towards further extending the work of the Central College, and expressed the hope that this recog-

Digitized by Google

nition by so important a body as the university might encourage the institute to maintain its pre-eminent position as an engineering college. In the course of some further remarks, Lord Halsbury mentioned that out of a staff of eight engineers working on the great Nile dam at Assuan, four of them are old students of the college. Lord Kelvin added a few sentences, expressing the thought that the governing body should exercise the utmost liberality in its treatment of the Central College and the Finsbury College in the matter of equipment. Both reports were unanimously adopted.

Municipal Trading.—A conference, under the auspices of the London Municipal Society, was held on the 28th ult. at the Constitutional Club, Northumberland-avenue, to discuss the question of municipal trading. Sir Edward Clarke, K.C., was in the chair, supported by a large number of members of Parliament and others, including Sir John Dorrington, M.P., Mr. C. A. Whitmore, M.P., Captain Jessel, M.P., Colonel the Hon. H. Legge, M.P., Mr. Sidney Morse, and Mr. J. A. Baines. The chairman having introduced the subject, the discussion was opened by Major L Darwin, who urged that they should set their faces against anything in the way of competitive trade being in the hands of municipalities, and contended that such undertakings as gas, electricity, and tramways should be left in the hands of private companies. He was convinced that municipalities could not trade as cheaply as private concerns. The germ of corruption would spread if they gave it a chance, and by means of municipal trade they were putting a new and a very great danger in their path. As to the tramway question, he argued that they ought further to restrict the power of veto which was possessed by the municipalities, and, among other things, they should press for the reappointment of the House of Commons Committee on Municipal Trading, or else for the appointment of a Royal Commission immediately on the subject. Mr. Whitmore, M.P., in the course of the subsequent discussion expressed the opinion that as long as they could keep private enterprise working well they should do so, but they must not declare that all municipal enterprise was bad. Sir John Dorrington referred to the undesirability of making use of municipalities for all purposes because of the tendency to restrict individual enterprise, and because it was very apt to burden the ratepayers with the cost of enterprises which were bound to be financially disastrous to the community. The discussion was closed by Sir Edward Clarke, who held that wherever there was anything in the nature of a monopoly, a municipal government, like the State Government, had a right to say that the monopoly, if granted at all, should be granted for the benefit of the community. One of the many dangers of municipal trading, however, was that of bringing a large part of the population into the direct service of the municipality—a mischief of the deepest possible character, leading to corruption in political affairs and mismanagement in municipal affairs to a great extent. He urged, therefore, that this requirement should be imposed on every form of municipal trading—namely, that the accounts of each form of municipal trading should be kept absolutely separate and distinct; and that the profits upon each particular branch should be devoted to the purposes of that particular undertaking. He would like to see the re-establishment of a strong committee on municipal trading, which ought to lay down, and no doubt would lay down, propositions of very great value. Those principles were that municipal trading should only be allowed in matters which were incidental to the good government and keeping of the district in which it was carried on. He did not include in that the provision of housing. He thought that within the limits mentioned municipal trading might not only safely be allowed, but in some respects would be advantageous.

Single-Phase Motors.—One of the most serious defects in the behaviour of single-phase motors is to be found in their lack of starting torque, to remedy which many ingenious devices have been developed. Writing on the subject in the *American Electrician*, Mr A. S. M'Allister says a simple method of producing the requisite quadrature magnetic flux for the purpose of giving a single-phase induction motor a starting torque is available in the use of "shading coils," which are extensively employed in alternating-current fan motors. Each coil consists of a low-resistance conductor surrounding a portion of a field pole. As ordinarily applied there is cut in each pole a slot parallel to the shaft of the rotor. In this slot is placed the conductor, which is connected by a closed path of high conductivity around a portion of the pole included between the slot and the side of the pole. The coil of each pole is placed similarly to that of the other poles, and the secondary revolves in the direction from that portion of a pole not surrounded by a coil towards the "shaded" side of the pole. The action of the "shading coils" is described as follows: Consider the field poles to be energised by single-phase current, and the current to be flowing in a direction to make a north pole at the top. Consider also the poles to be just at the point of forming; lines of force will tend to pass downward through the shading coil and the remainder of the pole. Any change of lines within the shading coil generates E.M.F., which causes to flow through the coil a current of a value depending on the E.M.F., and always in a direction to oppose the change of lines. The field flux is, therefore, partly shifted to the free portion of the pole, while the accumulation of lines through the shading coil is retarded. However, so long as the magneto-motive force of the field current is of sufficient strength and in the proper direction, the lines through the shading coil increase in number, although the increase is retarded, which is to say, that, even after the lines in the other part of the pole begin to decrease in number, the flux within the shading coil is increasing, and continues to increase till the exciting current drops to a strength just sufficient to maintain that density of flux which is within the coil. At this instant the flux in the shading coil has its maximum value as a north magnetic pole. As the flux on the other portion of the pole continues to decrease, the lines within the shading coil tend to decrease also; but the E.M.F. generated by their rate of change causes to flow a current which tends to prevent any change of lines, so that when the other portion of the pole contains no lines whatever there is yet within the shading coil an appreciable amount of flux, forming a north magnetic pole, the result being a shifting of the field from the unshaded to the shaded side of each pole. This is repeated when the magnetism reverses. The lines within the shading coil decrease with an increasing rate of charge, and a condition of zero lines within the coil is soon reached. At this instant there is a south magnetic pole at the "unshaded" end of the top field pole, and a north magnetic pole at the "unshaded" end of each adjacent field pole, and south and north magnetic poles begin immediately to form within the corresponding shading coils. Looking back over the process of formation of the magnetic poles, it will be seen that the north pole, though varying in strength, has travelled a counter clockwise direction. This process is continuous, and results in a truly rotary field. The one disadvantage of this method of getting a good starting torque is that it cannot be applied to motors of large size satisfactorily.

DONCASTER ELECTRIC TRAMWAYS.

On Monday last the tramways of the Doncaster Corporation were officially opened under most auspicious circumstances. The proclamation of peace was seized upon by the inhabitants of Doncaster as a good reason for a general holiday, and in consequence the streets were crowded with people to witness the procession of decorated cars which inaugurated the public service.

MR. W. H. R. CRABTREE, BOROUGH SURVEYOR.

COUNCILLOR THOS. WINDLE, MAYOR OF DONCASTER.

MR. W. WYLD, BOROUGH ELECTRICAL ENGINEER AND TRAMWAY MANAGER.

The history of the tramway undertaking at Doncaster commences in 1899, when the British Electric Traction Company brought forward a scheme for the provision of tramways in Doncaster and its suburbs. A light railway order was applied for with this object, and the opposition to it by the Doncaster Corporation took the form of a rival scheme, which is practically that inaugurated on Monday last. The work has been done under the Light Railway Acts, with the consent of the Light Railway Commissioners. The chief alteration which had to be made in the scheme then brought forward was that the tramway over the level railway crossing at Frenchgate, on the route to Bentley, had to be abandoned, owing to the opposition of the railway companies interested.

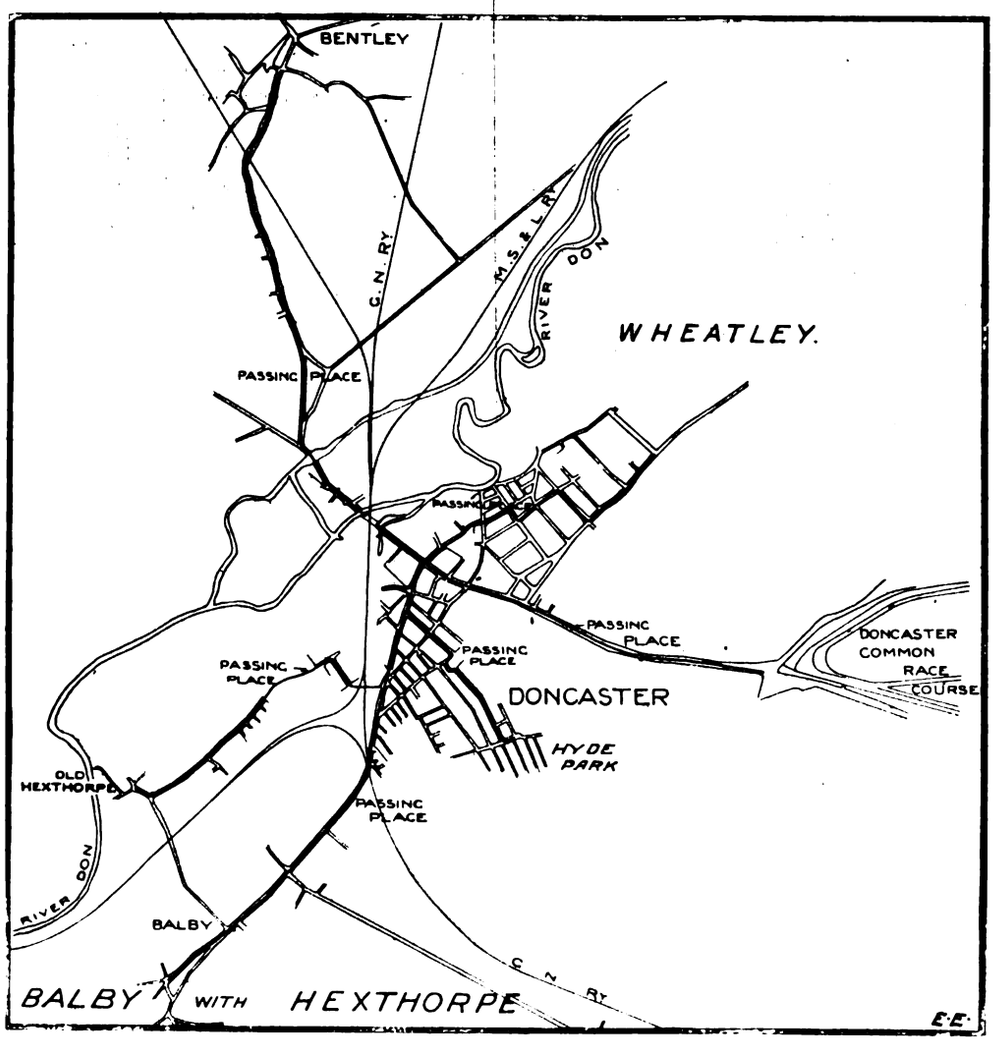

FIG. 1.—Map of the Electric Tramways at Doncaster.

Digitized by Google

This alteration is unfortunate, as it necessitates a break in the tramway connections to Bentley, in consequence of which every passenger has to change cars and walk over the level railway crossing. With this exception the scheme of the Corporation was sanctioned without alteration, and

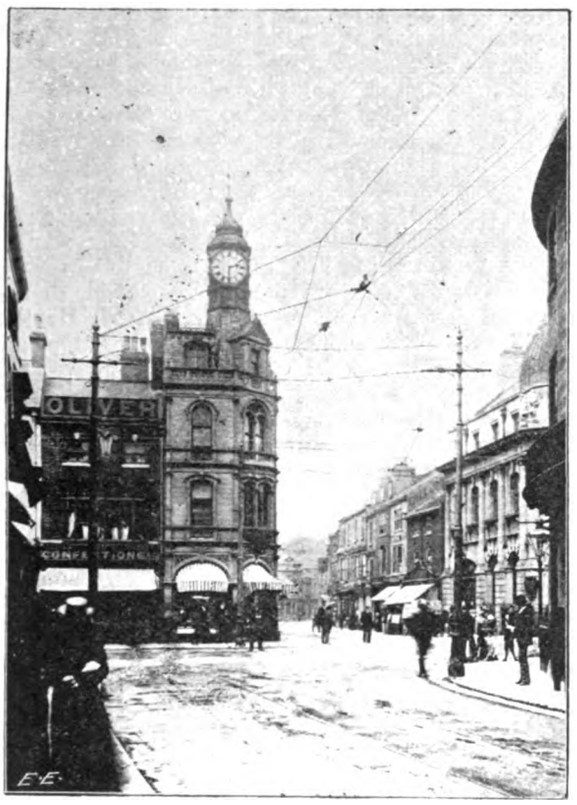

FIG. 2.—The Clock Corner, Doncaster.

the order, after confirmation by the Board of Trade, received the final approval of Parliament in 1899. For this promotion work the town clerk and the borough surveyor were chiefly responsible, but they were advised as to the work has been carried out. When the time arrived for the preparation of specifications for the electrical equipment the work was done by Mr. C. A. L. Prusmann, A.M.I.E..E., the then electrical engineer of Doncaster (now

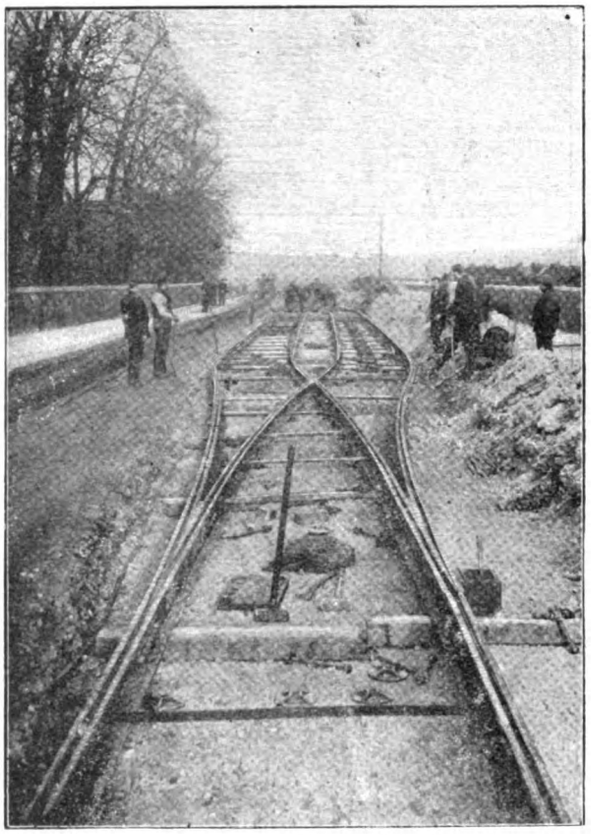

FIG. 3.—Rail-Laying at the Passing Places at Balby Road, Doncaster

borough electrical engineer at Swansea). Mr. Prusmann left for Swansea about the time the actual work was about to commence, and since he left, Mr. William Wyld, A.M.I.E.E., the borough electrical engineer of Doncaster,

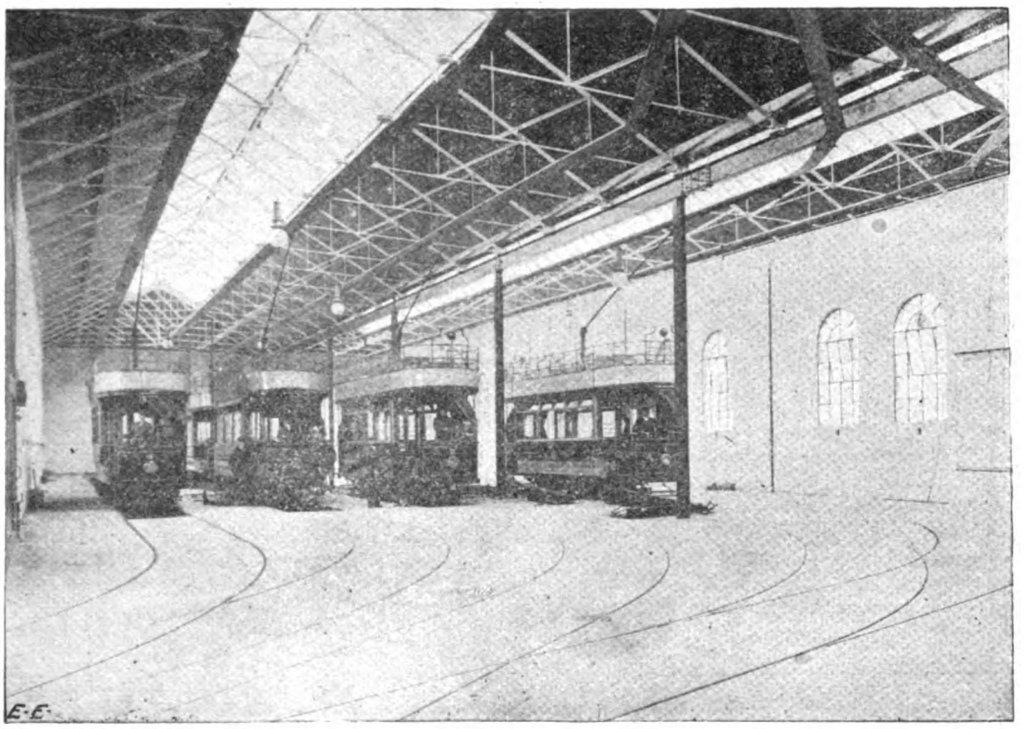

FIG. 4. View of the Interior of the Car Shed at Greyfriars Road.

electrical equipment and costs by Mr. J. N. Shoolbred, M.I.C.E. The plans and estimates for the construction of the various lines, car-sheds, etc., have since been prepared by Mr. W. H. R. Crabtree, M.I.C.E., the borough surveyor, under whose supervision the whole of this portion of the has had sole charge of the electrical equipment, and has had the care and responsibility in carrying out the whole of the electrical portion of the work. The Corporation has let every branch of the work by contract, but carried out the excavating, concreting, and laying of the track by

Digitized by Google

their own workmen, and these have been under the supervision of Mr. Tench, who has had considerable experience in constructional steelwork.

In the map (Fig. 1) we show the routes to be equipped under the orders now obtained, and a few words as to each

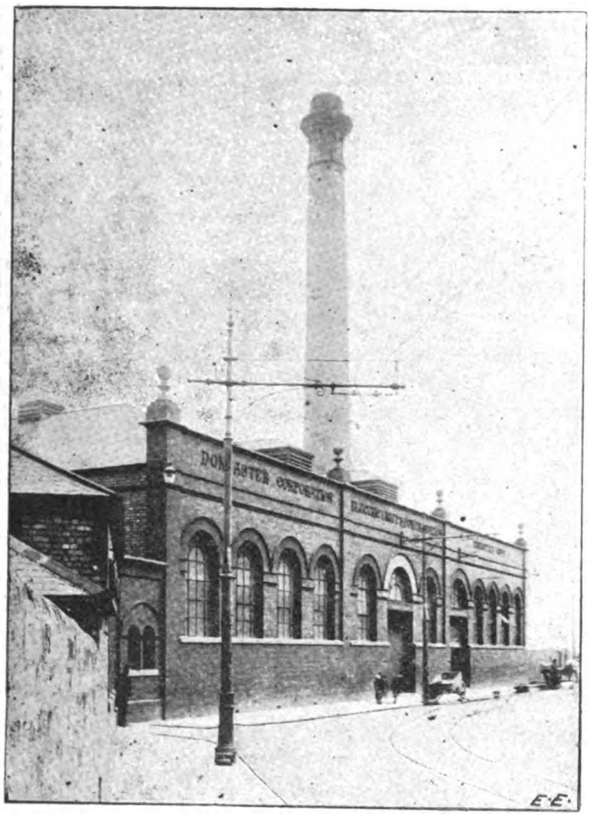

FIG 5.—The Outside View of the Electricity Works, showing Tramway Poles.

will be of interest. The line to Balby starts just outside the Great Northern Railway station in Station-road and terminates at Balby, where a tramway shelter has been constructed for the convenience of passengers. As there are three passing places on the way and the distance is one mile four furlongs eight chains, it will be possible to have four cars running and a quick service if necessary. At the commencement it is intended to run half-hourly from 5.30 a.m. to 8 a.m., and from then up to 11 p.m. a quarter-hour service. The line to Hexthorpe is a branch of the Balby line near St. James Church, and from this point to the terminus at Hexthorpe, a distance of one mile five chains, there is only one passing place provided. The construction of this section has involved a considerable amount of expenditure in addition to the ordinary cost of tramways. In the first place, the nine-arch bridge over the Great Northern and Great Central Railways had to be strengthened. Then at the junction of Hexthorpe-road the Old Plant Inn, with three adjoining shops and one house, have been set back, so as to increase the width of Hexthorpe-road from about 29ft. to 42ft. Further on the Corporation have caused Hexthorpe-road to be widened to the borough boundary by arrangement with owners of adjoining property. In the district of the Balby-with-Hexthorpe Urban District Council, where the Corporation own the adjoining land, they have set back the fence walls and made a new road nearly half a mile in length to a uniform width of 42ft. This has resulted in a good wide thoroughfare in the place of the old narrow road. At the Hexthorpe terminus the line is doubled so as to enable outgoing cars to proceed the moment the incoming car arrives. The same plan will be adopted at all similar termini. It is expected that the traffic on this line will be a constant growing one, owing to the number of new houses erected and in prospect in the neighbourhood of the Great Northern new plant works. It will develop the building estates of the Corporation in that district, and affords a speedy means of access to Hexthorpe Flatts, which belong to the Corporation, and are a pleasant resort in summer. Another line runs from Station-road to Grey Friars-road, and one more still continues the line along Grey Friars-road to the car-shed. The sections which were opened to the public with the Board of Trade sanction on Monday last are the following: from Station-road to Balby, the Printing Office-street loop, from St. Sepulchre's-gate to Hexthorpe, from Station-road to Grey Friars-road, and Grey Friars-road. The total length of routes opened is about 3¼ miles, but inasmuch as these include all the special track work at the car-shed, the Clock-corner (Fig. 2), Station-road, and the various junctions along the route, it is expected that the remaining lines, being of a more straightforward character, will be completed during the summer. Already a portion of the double line to the racecourse, and part of the single line to Hyde Park, have been constructed. The total length, inclusive of the double line to the racecourse, and the passing places and junctions, will amount to nine miles of single line. Sunny Bar is now being widened so as to enable the tramway to be laid through.

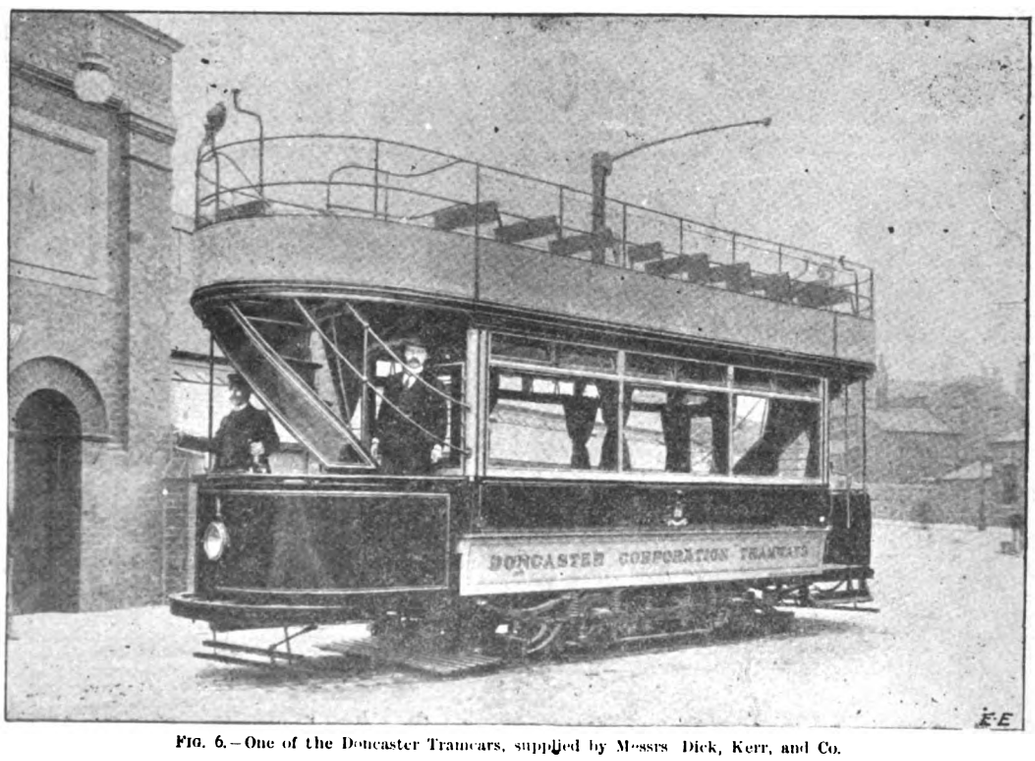

FIG. 6.—One of the Doncaster Tramcars, supplied by Messrs. Dick, Kerr, and Co.

Digitized by Google

The rails used at Doncaster are of steel, 60ft. lengths, laid to a 4ft. 8½in. gauge, and weighing 94lb. per yard. Following the example of Hull, these rails are of the centre-grooved type, with diagonal ends, coupled at the rail ends by fishplates and sole-plates, and held in position by cross ties and holding-down bolts bedded in the concrete at 6ft. intervals. In Fig. 3 is given a view of these rails as laid at a passing place on the Balby-road. The whole of the steelwork has been supplied by Mr. H. Gielgud, of 140, Leadenhall-street, London, acting for the Société Anonyme des Acieries d'Angleur. Mr. E. A. Jones, of Brussels, has tested the steel at the works before delivery, and found entirely satisfactory. Messrs. Hadfield's, of Sheffield, have supplied the whole of the points, crossings, and special track work. Whilst the track was laid the underground conduits supplied by the Albion Clay Company, of Woodville, were also put in position ready for the feeding cables. The cement has been supplied by Messrs. Skelsey's Adamant Cement Company, of Hull; the holding-down plates by Messrs. Burnett and Co., of Hexthorpe; and manhole covers by Messrs. George Harvey and Co., of Chapeltown. The paving setts have been supplied by Messrs. the London Basalt Stone Company; the Balby Brick Company have supplied bricks; and Messrs. Farr, Longbottom, and Charles sundry items. Messrs. Woodhouse and Co. have supplied the cast burrs for the steel poles.

The Grey Friars-road car-shed (Fig. 4) is situated directly opposite the electricity works. The car-shed construction involved building over part of the River Cheswold, with very deep walls on the river side. The shed is 200ft. long, and will accommodate 20 cars, but only 15 are now delivered or on order, and of these two will be housed in the Bentley car-shed. This car-shed was designed throughout by Mr. Crabtree, and built to his supervision by Messrs. H. Arnold and Son. The shed is well lighted, and is most suitable for its purpose. The other car-shed to receive the cars on the isolated section of the tramways beyond the railway crossing is situated on the vacant land in Marshgate. The lighting of these sheds was carried out by the Northern Electrical Company.

The whole of the feeding cables have been supplied by Messrs. the Callender Cable and Construction Company, and are of their usual type for a drawing-in system. The same firm also supply the section pillars, which are placed at half-mile intervals along the track. For the most part the overhead equipment consists of poles with brackets (Figs. 2 and 5) supporting the trolley wires, at a distance of 40 yards apart, but in portions of St. Sepulchre-gate and at the racecourse, where the road is of considerable width, there are poles on each side with a connecting span wire supporting the trolley wire. This method of support was adopted by the Corporation on the racecourse route with a view to making the poles as little noticeable as possible. In fact, when the trees are in full foliage, it is expected that the poles on this route will be almost hidden by the trees. Guard wires are provided in all cases where telephone and other wires are above the trolley wires, so as to prevent their coming in contact should the wires above break. The drivers will be provided with indiarubber gloves, so as to be able to handle the trolley wires in case of breakage. The whole of the overhead work has been done by Messrs. R W. Blackwell and Co.

The 15 cars (Fig. 6) supplied by Messrs Dick, Kerr, and Co., Limited, are all of the same design, and are of the top-seat, reversed-staircase, single-truck type, suitable for the standard gauge of 4ft. 8½in. They are mounted on Brill 21-E trucks, the equipment consisting of two 25-A motors and rheostatic brake controllers. The total over-all length of car is 27ft. 5in, the clear height inside at centre 6ft. 9in., and the over-all height from rail 13ft. 2in. The seating capacity of these cars is 22 inside and 34 outside. The trucks have a wheel base of 6ft., the diameter of wheels being 30in. and the axle 3¾in. The wheels are of best chilled iron, and the trucks are fitted complete with hand brakes. The floor frames are built up of pitch pine and oak, and there are the usual openings over the motors to afford convenient access. The interior woodwork is of quartered oak, and over the side windows is a cornice of embossed mouldings. The panels of the doors and partitions are fielded. The cars are fitted with hand brakes, and there is the usual equipment of sand-boxes, gongs, etc. The finish of these cars and their upholstering was much admired on Monday.

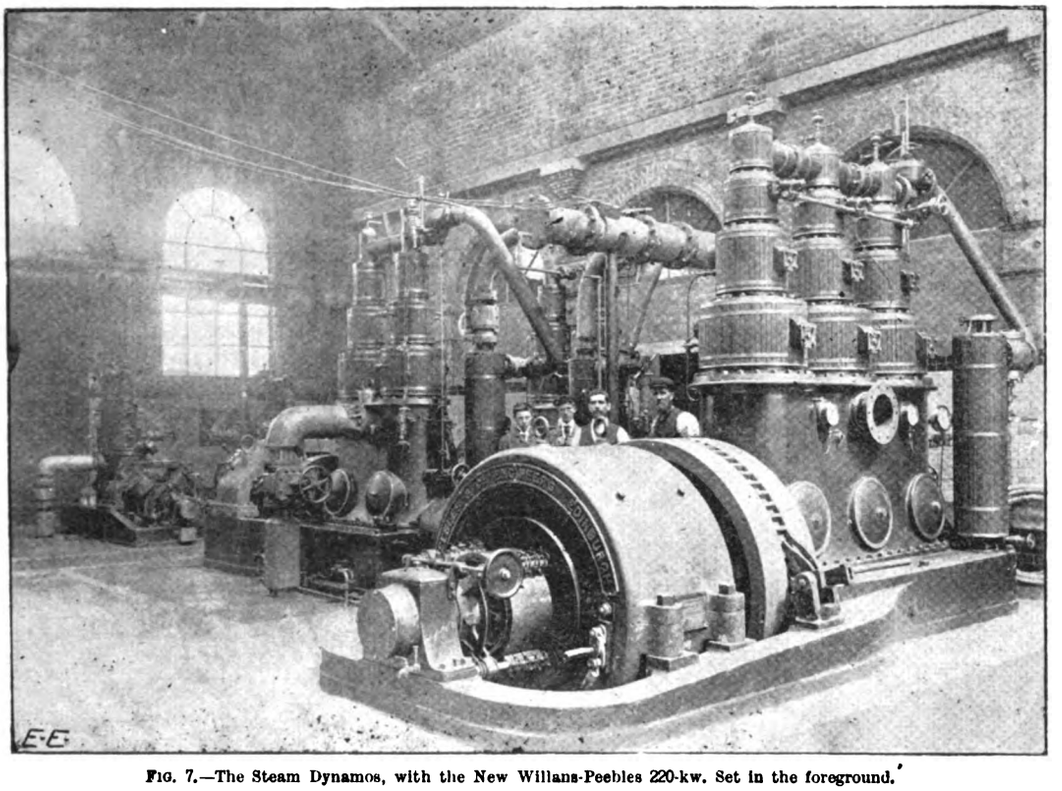

FIG. 7.—The Steam Dynamos, with the New Willans-Peebles 220-kw. Set in the foreground.

Having now described the tramway equipment, a few words are necessary with respect to the generating works. It was the fact that the Corporation already owned the electric lighting undertaking that was one great argument in deciding that they should also keep the tramway work in their own hands. We gave in our issue of April 6, 1900, a full description of the electric lighting works, which give a supply on the three-wire system. In the works as originally illustrated by us there were three 56-kw. machines for working between the middle wire and

Digitized by Google

either of the outers, and two of 150 kw. wound for 500 volts. The dynamos were of the Mather and Platt make, whilst Willans engines were used throughout. In making provision for the tramway load, a new set, consisting of a Willans engine driving a Bruce-Peebles 220-kw. dynamo, was installed. This dynamo is over-compounded, but can be used as a shunt machine to work on the lighting 'bus bars. Mr. Wyld has also had a compound winding added to one of the Mather and Platt 150-kw. dynamos so that it can be used for tramway purposes. This can be seen in Fig. 7, while Fig. 8 gives a good view of the whole of the plant and switchboards in the engine-room. The traction switchboard (Fig. 9) was supplied by Messrs. Dorman and Smith, and to the right of it can be seen the throw-over switches which connect the two compounded dynamos on to either the lighting or the traction switchboard. It will, of course, be a great advantage to the electric lighting undertaking to supply the tramway load, but up to the present the actual price per unit has not been fixed. The estimated cost of the tramway undertaking is £77,500, and we gather that this sum is not likely to be exceeded. The undertaking has the advantage over many others, in that it starts with a clear field, as there were no tramways in Doncaster to be bought out. In consequence the capital charges are not excessive, and the undertaking should be financially successful from the very first.

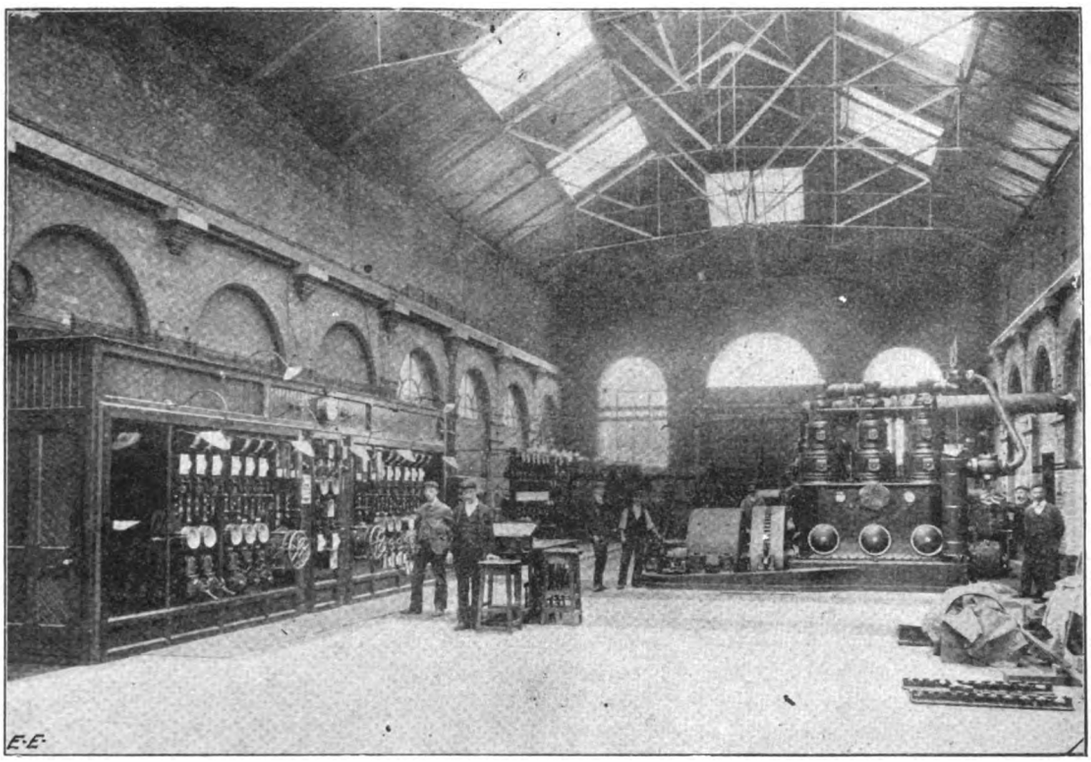

FIG. 8.—The Engine-Room of Doncaster Electricity Works.

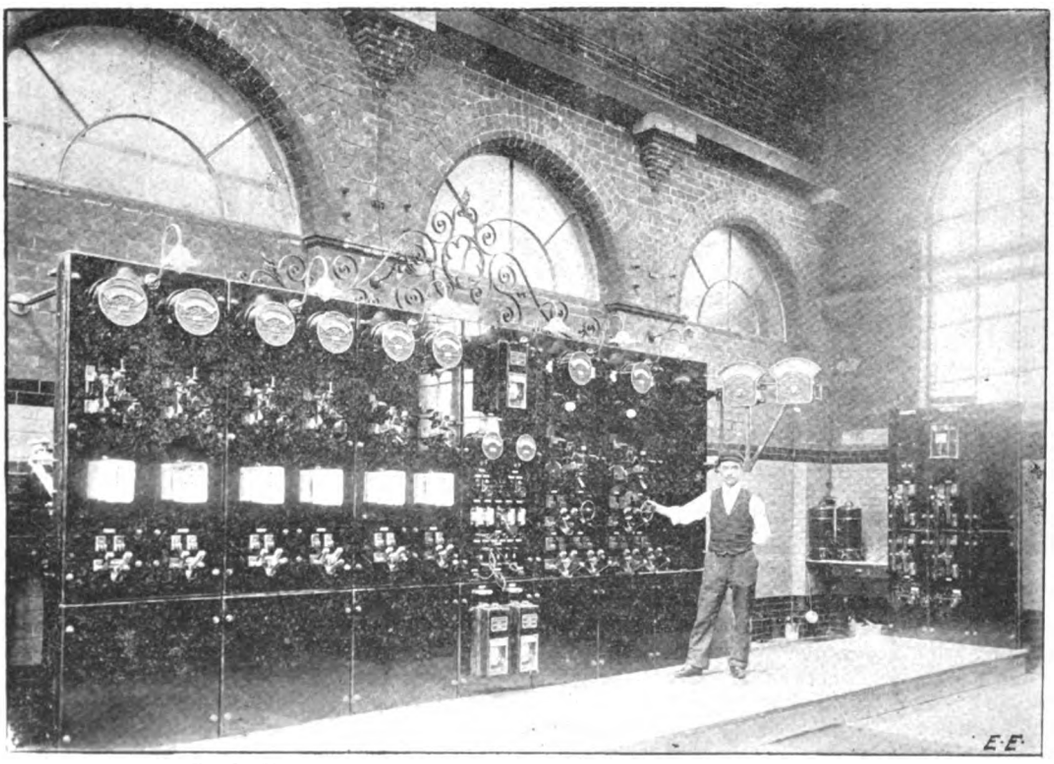

FIG. 9.—The Doncaster Traction Switchboard, made by Messrs. Dorman and Smith.

The working of the lines will be in the hands of Mr. W. Wyld, the borough electrical engineer, who will act as tramway manager under the direction of the Tramway Committee. The lines which were opened on Monday

Digitized by Google

last were inspected previously for the Board of Trade by Major Druitt, R.E., and Mr. A. P. Trotter. The result was a clean bill of health.

The opening ceremony was somewhat marred by the fact that the public stormed the car-shed after the guests had entered, and practically filled the space round the impromptu platform. The noise in consequence rendered a good portion of the speeches inaudible. Councillor Smith, the chairman of the Tramways Committee, in presenting a gold key of the car-shed to the Mayor, commented on the large amount of time which his committee had expended in investigating the tramways systems in other towns. They finally agreed to follow the example of Hull and to use a centre-groove rail. He alluded to the large amount of extra work which the construction of the tramways had brought on Mr. Crabtree, the borough surveyor, while the praise of the Board of Trade inspectors would in part compensate him for the same. The old art of prophecy was not extinct. They had had the prophets prophesying that when they got cars in Doncaster these would have to be drawn by horses. Others that Doncaster would never have cars running at all. Others that no cars would run in the year 1902; which prophecies had already been falsified. The prophets, now that all their previous prophecies had failed, said, "Yes, you will see they won't pay." How comforting Some of them believed they would pay. What was wanted was for the 42,000 inhabitants of the town and district to make up their minds that at least they would have a car ride once a week. The interest and sinking fund to which they were already committed, when the whole of the lines were completed, amounted to about £70 per week. The cost of working and wages would be about another £100, which was equivalent to 7d. per car mile. They felt confident that in providing a quick service at the uniform rate of 1d. for the journey they would see their cars laden with passengers, and that both pleasure to the inhabitants and profit to the town would be the result of this the latest and great enterprise which the Corporation had undertaken on behalf of the people. Councillor Smith added that the contractors had one and all given the committee general satisfaction, and they were pleased to see them all represented at the opening ceremony. The Mayor then declared the car-shed and tramways open, and wished the undertaking every success. He hoped the tramways would soon become a paying concern.

After a vote of thanks to the Mayor had been proposed and carried, Councillor Dowson, the chairman of the Electric Lighting Committee, presented Councillor Smith with a gold watch charm, which was an exact model of the controller handles used on the car.

The next procedure was the presentation by Mr. Beeton, representing Messrs. Dick, Kerr, and Co., of two silvered controller handles to the Mayoress and Mrs. Smith. These two ladies drove the first two cars in the procession which was then formed to go over the different routes. The proceedings were terminated by an excellent luncheon served in the historical Mansion House of Doncaster, in the menu of which "Corporation tarts" appeared. We believe that the date on the Roman receipt for the manufacture of these articles cannot be deciphered, but the tarts have for centuries been forthcoming whenever a luncheon or dinner is given at the Mansion House. After the usual loyal toast, the toast of "The Contractors" was given and the health of Councillor Smith, the chairman of the Tramways Committee. We have not for some time attended an opening so well organised as that of Doncaster, or of a scheme which promises to be so successful financially and so useful to the inhabitants of the town served.

FORMERS AND FORMER-WINDING.

BY F. W. DAVIES.

(Continued from page 777.)

V. Formers for Drum Armature Coils (Bar-Wound).

A coil or section of a symmetrically-wound bar drum armature is of precisely the same contour as an equivalent coil for an armature with formed wire winding. A bar winding such as that used in some of the designs of Mr. Gisbert Kapp, in which the bars are of various lengths and the end connections made with semi-circular plates is unsymmetrical; and, therefore, does not come within the genus of former-winding. The two distinctive types of former-winding for bar-wound armatures are the evolute and the barrel, the intermediate or bastard type of winding being impracticable with bar winding. The evolute bar winding has been in constant use for 10 years or more. Several patents have been taken out for this method of winding, notably by Messrs. Siemens and Messrs. Crompton.

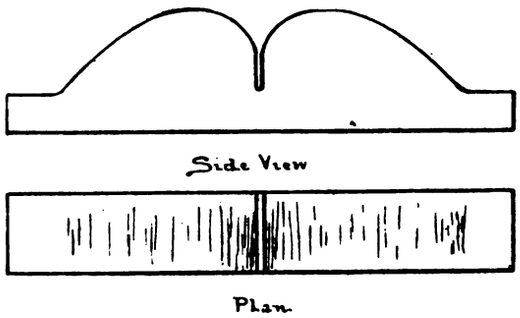

Fig. 13.—Former for Evolute End-Connectors for Bar-Wound Armatures.

Both this and the barrel winding are too well known to require much description. With the evolute winding the bars are straight and require no forming whatever. The evolute end connectors, by means of which the bars are cross-connected at the ends, however, require a former or templet on which they may be formed to their well-known evolute shape. Such a former is of the simplest description, and for end connectors which are fairly pliable may be cut out of a block of hardwood. If the end connectors are of stout, stiff copper, it should be made in metal. A sketch of the former is given in Fig. 13. Each coil of the armature consists of two straight bars and two end connectors. The latter are usually mounted on a sleeve at each end of the armature. Each coil may be comprised either of two bars of equal (or, more correctly, nearly equal) length; or of one long bar and one short bar, according to the way in which the end connectors are arranged. The two methods are shown diagrammatically in Fig. 14. For

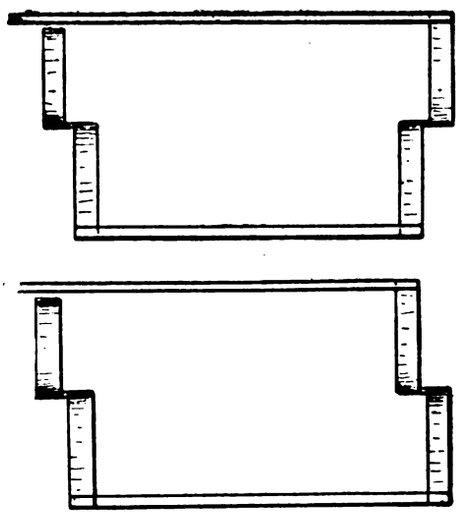

Fig. 14.—Diagrammatic Plans of Bar-Wound Coils, showing the Alternative Arrangements.

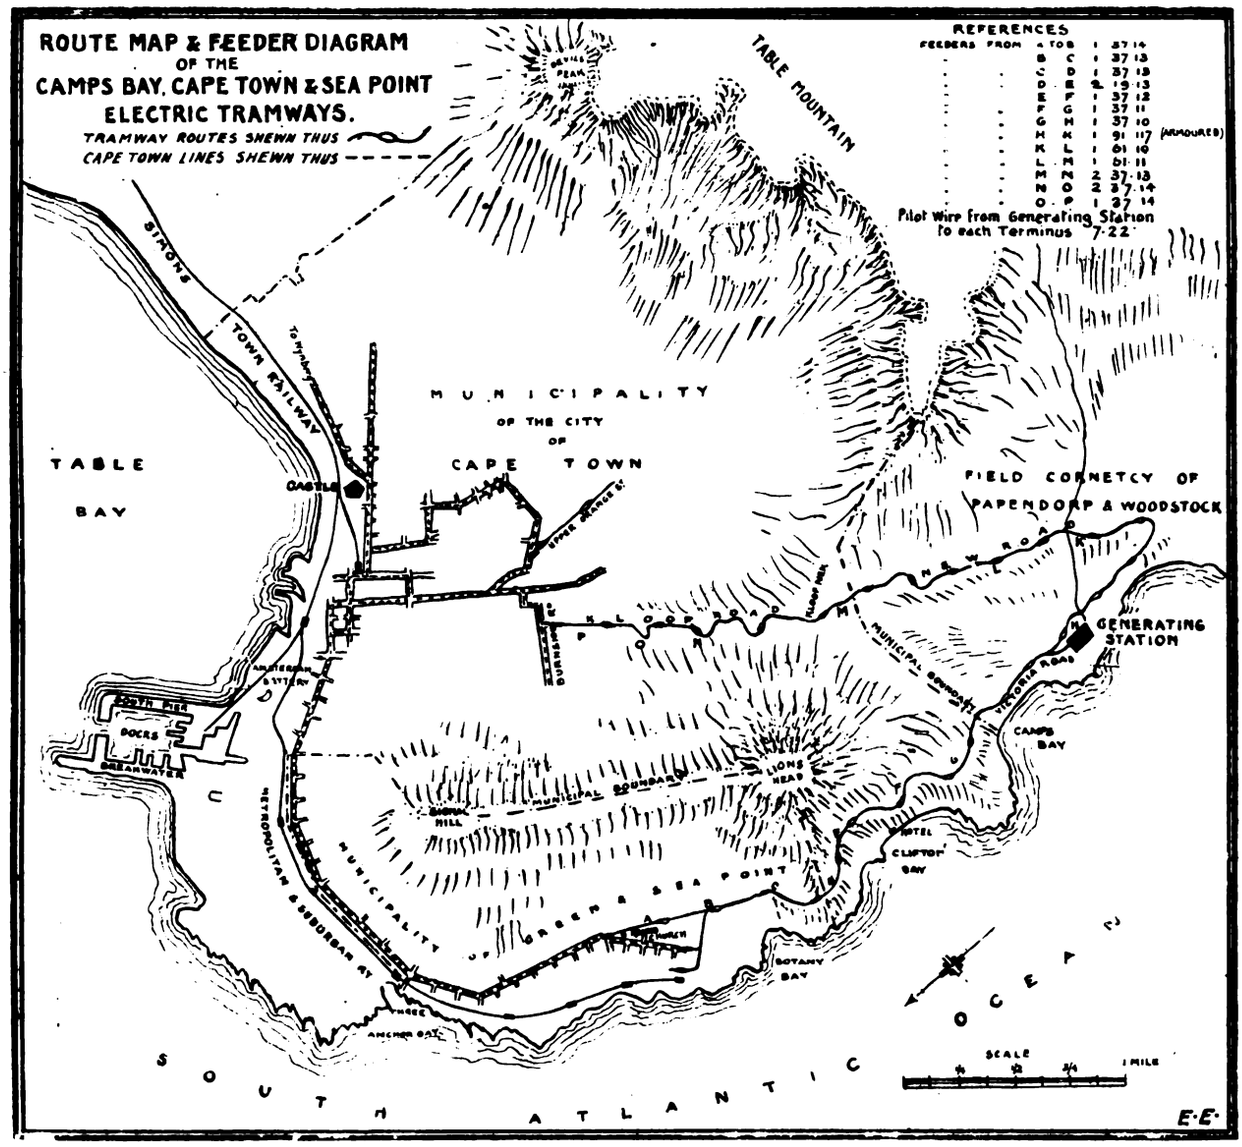
some reasons it is more convenient to have the two bars of a coil of nearly equal length, as shown in the lower view of the figure; but this arrangement has the disadvantage that every alternate bar projects beyond the others at each end of the armature. This introduces serious difficulties in the soldering up of those ends of the bars which come between the projecting ends. It is far preferable to have each coil made up of one long bar and one short one, as shown in the upper view of the figure, as then all the short bars can be put on the armature first and soldered up without difficulty before the long bars are put on.

The barrel type of winding for bar-wound armatures has not been in actual use for so long a time as the evolute

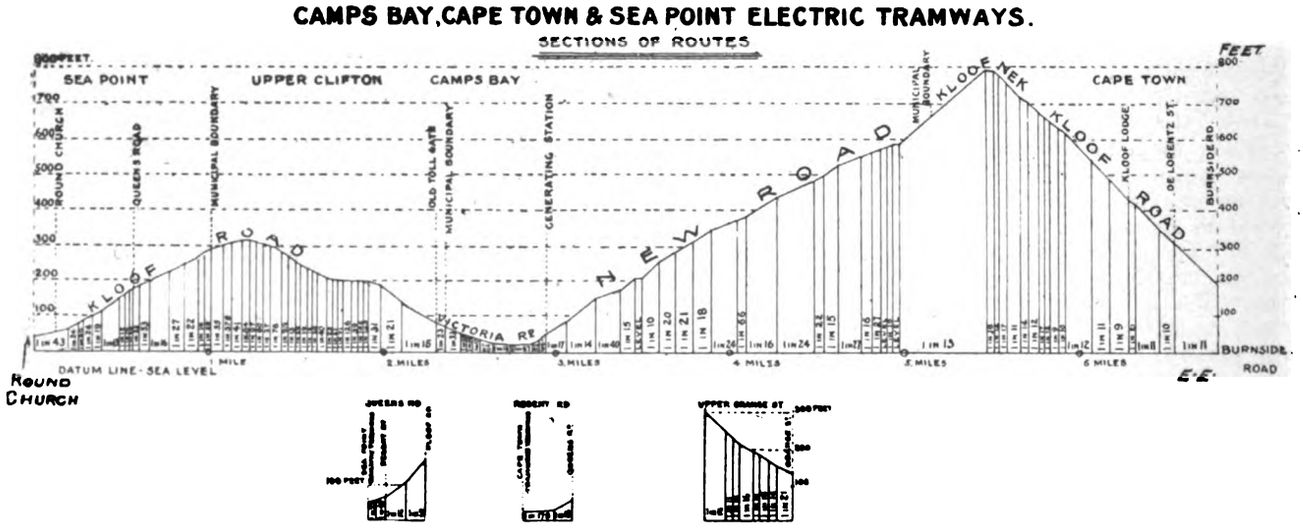
Digitized by Google

type of winding, and it is only of late years that it has come into prominence. It offers better facilities for ventilation than does the evolute winding. Not only so, but edge of the coil trough is cut away all round the former so as to be level with the bottom of the trough. This is in order that the coil may the more easily be tapped into



in many instances it is decidedly cheaper as regards both material and labour; and, moreover, is not so liable to a breakdown. Evolute end connectors frequently give trouble where they are grouped together on the sleeve, as the arrangement

the required shape with the mallet. The coil may consist either of two bars, fastened together at the end of the armature remote from the commutator by being soldered into a clip or shoe; or it may be formed from a single



is highly favourable to the accumulation of copper dust. The former for the barrel type of bar winding may be of similar construction to the former shown in Fig. 11, but with the difference that that part of the block which forms the outer

long bar bent like a wire-wound coil. This latter method is certainly the better and cheaper one to employ where the conductor is light and flexible enough to allow of it. For conductors of large section, however, it is advisable to adopt

Digitized by Google

the previously mentioned plan—that is, to make each coil or section of two bars, which are soldered into a clip, as the bending of a heavy conductor is a very difficult operation.

(To be continued.)

CAMPS BAY, CAPE TOWN, AND SEA POINT TRAMWAYS.

The accompanying map of the above line, which was fully described in a recent issue, reached us too late for insertion in that issue. It is of great interest when consulted in connection with the section of the work also given below, as showing what great difficulties as to grades have been overcome by electric traction in the able hands of Messrs. Dick, Kerr, and Co. We would note our readers to refer to our issue of the 23rd inst. for details of the equipment when looking at the map.

ENGINEERING STANDARDS COMMITTEE.

A deputation from the Engineering Standards Committee recently waited upon the First Lord of the Treasury to discuss the question of standardisation, and a report of the proceedings has now been published. The deputation consisted of the following gentlemen: Mr. Mansergh (chairman of the committee), Mr. Charles Hawksley, Mr. Maw, Mr. Whitwell, Mr. J. Swinburne, Sir William Preece, Colonel Crompton, Mr. McDonald, Mr. A. Denny, Mr. Windsor Richards, Prof. Unwin, Mr. Ainsworth, Dr. Tudsbery, and Mr. Leslie S. Robertson (secretary).

Mr. MANSERGH stated that the question of standardisation was originally brought before the council of the Institution of Civil Engineers by Sir John Wolfe Barry, and that the Institution of Mechanical Engineers, the Institution of Naval Architects, the Iron and Steel Institute, and the Institution of Electrical Engineers were co-operating with them. The work of the committee was originally divided into four sub-committees: (1) bridges and building construction, with Sir Benjamin Baker as chairman; (2) sections used in shipbuilding, of which Mr. Denny was chairman; (3) rails, with Sir John Wolfe Barry as chairman; (4) railway rolling-stock underframes, with Sir Douglas Fox as chairman. Two other sub-committees had since been added: (5) electrical plant (chairman, Sir William Preece); and (6) locomotives, of which Sir Douglas Fox is chairman. He hoped that the deputation would be able to make out a sufficiently strong case to enlist the active support of the Government.

Mr. ARCHIBALD DENNY, the chairman of the Ships Committee, said the work of this committee was divided into two parts—the fixing of standard sections of materials, and the fixing of standard tests. With regard to the latter, he anticipated no difficulty in reconciling the requirements of the three registry societies, the Admiralty, and the Board of Trade, because they involve difficulties for the steelmakers. With regard to the standard sections, his committee had arrived at a provisional decision. Up to the present the various supporting institutions had contributed towards the expenses of the work, but they hoped that the Government would now recognise the work as being worthy of their support.

Mr. J. SWINBURNE, as president of the Institution of Electrical Engineers, spoke on behalf of the electrical industry of the country. A certain amount had been done already, and they gratefully acknowledged the assistance of the Government with regard to the wire gauge, but there was a great deal to be done in standardising besides wires. They wanted to get dynamos and their engines standardised, so that they could be ordered from different makers and yet be found to fit. The American Institute of Electrical Engineers had taken the matter up, and something ought to be done in this country. Electrical traction was one of the cases in which this country had suffered enormously from lack of standardisation. In America the traction plant was mostly made by one or two very large concerns, and the trade, being in the hands of these concerns, they could standardise for themselves. In this country there was a large number of firms, and standardisation could not be effected unless it were done more or less officially. A considerable amount of money could be saved if standardisation were carried out now instead of waiting until a multiplication of designs were in use. The Government were directly interested in telegraphs, telephones, and electricity on board ship, and if the Government would take the matter up and work with the committee it would enormously benefit the electrical industry of this country.

Mr. WINDSOR RICHARDS, past-president of the Iron and Steel Institute, said that the steel trades of the country were greatly hampered by the fact that the rolled sections of rails, tramroad rails, and girders were not standardised, and that the testing to ascertain the quality of the steel varied too much. He spoke of the trade being hampered from his own knowledge as a director of two very large works, one in the North of England and the other in South Wales, the combined capital of the two being over £9,000,000, some 30,000 workpeople being employed. In the works referred to above several thousand tons of rolls were kept constantly in stock, and the amount of money uselessly invested in rolls over the whole country must be enormous.

Colonel CROMPTON, as an electrical manufacturer, could support what Mr. Swinburne had said about the electrical industry—viz., that it was greatly hampered from the fact that no recognised standards in sizes of the material were to be found.

Mr. LESLIE S. ROBERTSON, secretary, described what had been done in Germany, France, and America with regard to standardisation

The deputation stated that they had considered the question of the use of the metric system, but after very careful consideration they could not see their way to recommend its adoption unless its introduction were made compulsory by the Government.

Further remarks were made by Mr. HAWKSLEY, president of the Institution of Civil Engineers, Sir WILLIAM PREECE, Mr. DEAN, and others.

Mr. BALFOUR, in reply, said the advantages of standardisation were obvious. After what had been said no human being could have a doubt as to the importance and magnitude of the subject. As far as he could offer an opinion he entirely agreed with the views expressed by the members of the deputation. It would be necessary for him to lay the matter before his colleagues, but he was authorised to say that both the War Office and the Admiralty were prepared heartily to co-operate with the efforts of the committee in the direction of standardisation. As these two departments were the largest consumers of iron and steel their co-operation would be absolutely invaluable in furthering the objects of the committee. He could hardly add more at the present time, but would very glad to lay the views expressed by the deputation before his colleagues in the Cabinet.

The deputation then withdrew.

TELEPHONIC COMMUNICATION WITH FRANCE.

A convention drawn up by the British Post Office has just been signed by the French Minister of Commerce providing for telephonic communication between London and some 300 of the larger industrial cities in France. Hitherto the telephone line to Paris has been almost exclusively used for Stock Exchange and Press messages, but with the new arrangement there is likely to be a large increase in the number of calls. A uniform charge of 8s. for a three minutes' conversation, which is the present Paris rate, will be made, and the use of the system will be restricted to subscribers to the State telephones of both countries.

Folkestone.—A petition to the Board of Trade for an extension of time for the commencement of the proposed tramways has been approved by the Town Council.

HOLMES MOTOR EQUIPMENTS.

Last week we had the opportunity of interviewing two or three of the engineers of Messrs. J. H. Holmes and Co. who devote their time to the motor department of that firm. We were particularly interested with the Holmes-Clatworthy patent system for driving web newspaper printing machines by electricity. In previous issues we have referred to this system, but until now we have not had the opportunity of giving an illustration like Fig. 1, which shows the motor equipment as supplied to a large printing machine in the offices of the Northern Press and Engineering Company, of South Shields. It will be seen at once that in this case there are two distinct equipments on the Holmes-Clatworthy system, and this arrangement has been made in order that the printing machine can be used for various purposes and in various sections—*i.e.*, the whole of the printing machine working together can be used to print off a full daily paper, or one half of it can be employed to print an evening paper while the other half is standing. In consequence, the two electrical equipments are independent and only work as one when the whole printing machine is required at the same time. Each of the individual equipments consists of a small 3-h.p. motor which drives the main shaft of the larger 25-h.p. motor by means of worm gearing. This larger shunt-wound motor is connected to the printing machine. A single controller operates the two motors. In starting up, the small motor is first switched on and brings the speed of the cylinder of the printing machine up to 10 revolutions per minute. It can be regulated to run slowly at any speed, from two revolutions up to this. When the speed of the cylinder has reached about 10 revolutions, the large motor is switched on and takes up the work. A clutch in the worm gear is then over-run and released, and the small motor automatically shuts down. Owing to it being a series-wound motor, it follows up the speed of the larger one until the current is small, when the automatic switch breaks the circuit. The controller is then moved on round until the printing machine is up to full speed, which is about 200 revolutions of the cylinder per minute. To show the advantage of using the small motor to overcome the starting friction of the printing machine, Mr. Clatworthy made some experiments at Liverpool as to the minimum current required to start up first with the small motor and then with the large. It was found that only 13 amperes at 200 volts, or 10 per cent. of the full load current, was required with the small motor,

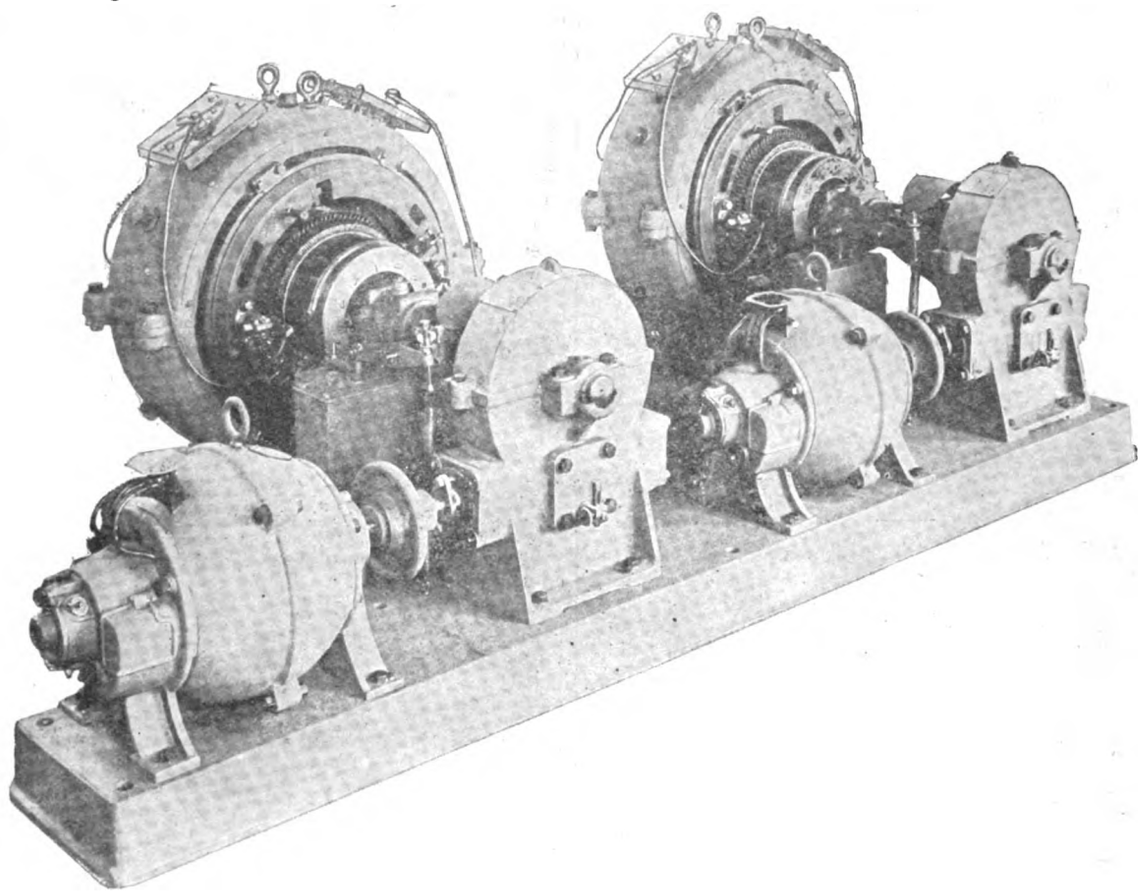

FIG. 1.—Two 25-h.p. Holmes-Clatworthy Equipments for Driving a Printing Machine.

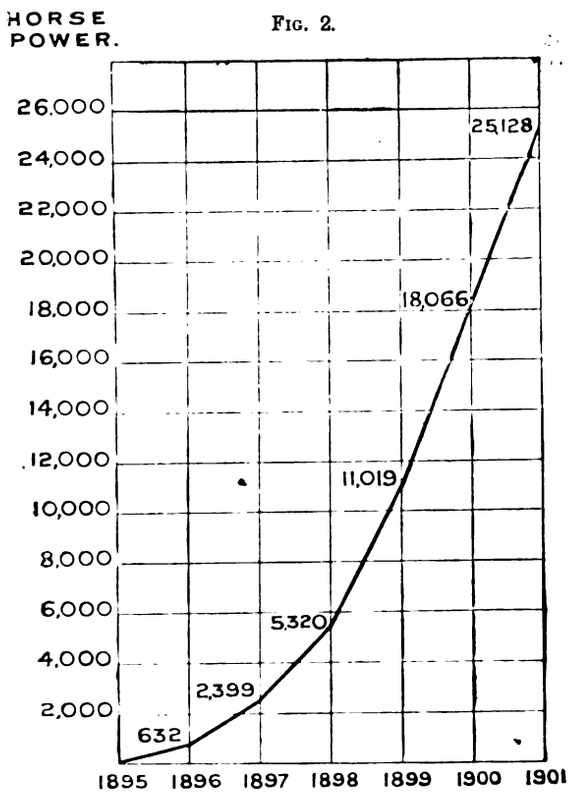
FIG. 2.



MOTORS.

CURVE SHOWING YEARLY PROGRESS OF SALES IN HORSE POWER.

Digitized by Google

whereas 160 amperes had to be passed through the large motor before the machine began to move. These Holmes-Clatworthy combinations have stood the test of several years' running, and it is of interest to note that the firm have received a large number of repeat orders from those newspaper printing firms who first tried them. For instance, the *Globe* Company have 10 of them at work, and the *Liverpool Courier* six, we believe. The curve (Fig. 2) shows how the output of motors manufactured by the above firm has increased of late years, and we believe we are correct in saying that the bulk of these motors are of the Lundell type. In Fig. 3 we show one of the 7½-h.p. motors used to drive by means of worm wheel two shear-leg hoists. The hoist is arranged for two speeds—*i.e.*, 34ft. per minute when lifting 1½ tons, and 10ft. per minute when lifting five tons. Fig. 4 gives three views of a recently-designed motor controller introduced by the firm, which is of special service for large motor work, where it is essential that the current taken from the main shall not exceed a predetermined limit, and that there shall be ample contact for the large currents to be dealt with. The screw adjustment of the controller contact ensures the slow starting up of the motor, and the arrangements are such that the circuit is immediately broken if the supply should be turned off. This starting and controlling gear is designed on engineering lines, and it will in consequence survive a time test, as is not the case with certain types of starting switches designed to sell. The success of Messrs. J. H. Holmes and Co. in connection with electrical power distribution is an indication of the rapid way in which

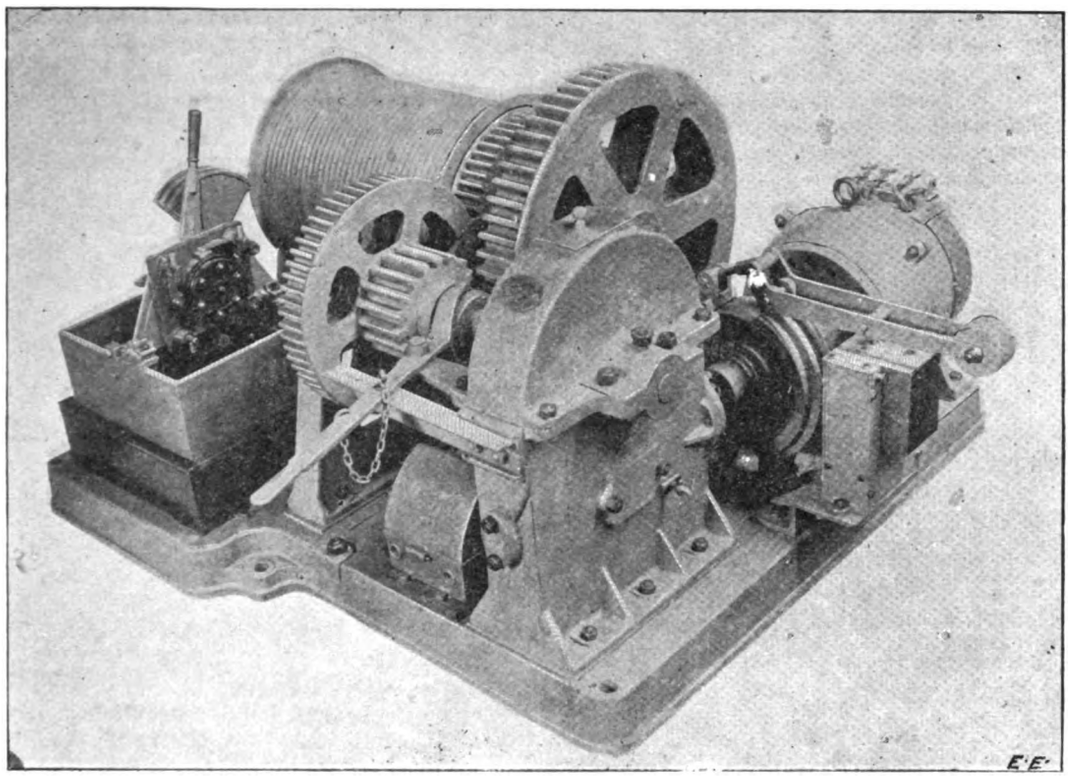


FIG. 3.—A 7½-h.p. Motor Driving Gear for Shear Legs Hoist.

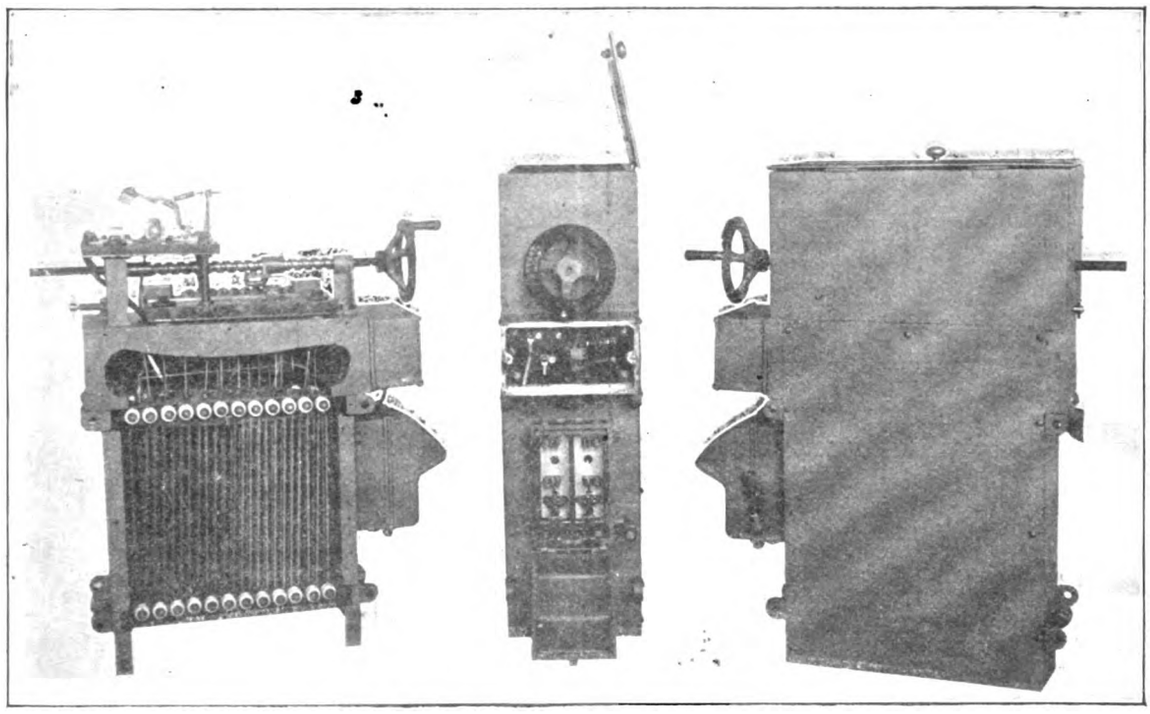

FIG. 4.—A New Type of Motor Starting Switch and Controller, made by Messrs. J. H. Holmes and Co.

Digitized by Google

this class of work is increasing in this country. It is also interesting to know that export orders are being secured in the face of severe foreign competition.

ELECTRIC TRACTION PROGRESS.

In our issue of the 16th ult. we reprinted a paper by Mr. Philip Dawson on the above subject, and the general manager of the Corporation tramways at Dover has just written us pointing out a discrepancy which has occurred in Table V., on p. 696. In that table the ratio of expenses to receipts at Dover was given as 85 per cent. The actual figure, we are informed, is 72 per cent, as the other figures given will show. As the article in question will doubtless be much used as a standard for comparison, we take this opportunity of making this correction.

TUBE BILLS IN PARLIAMENT.

LORD WINDSOR'S COMMITTEE.

FRIDAY, MAY 31.

Lord Windsor's Select Committee met again for the purpose of considering the compensation clauses to be inserted in the Tube Bills which have been passed by this and Lord Ribblesdale's Committee.

Mr. Balfour Browne, K.C., on behalf of the combined Piccadilly and City and London United Electric Railways Companies, submitted a clause providing "that if any building shall have been injuriously affected, either by the construction of the railway or works, or by the working of the railway, any owner or lessee of any such building shall be entitled to recover from the company compensation for any such damage proved to have been actually caused to such building," and that any question of disputed compensation should be determined by an arbitrator, who, failing agreement, was to be appointed by the president of the Surveyors' Institution.

Mr. Littler, K.C., brought up a clause on behalf of the Brompton and Piccadilly-circus Railway similar to that suggested by Mr. Balfour Browne, with the exception that the arbitrator, failing agreement, was to be named by the Board of Trade.

Mr. Balfour Browne said he did not press that point.

Mr. Littler said his clause also provided that the railway company should, even before the opening of the line, have the right to go in and remedy any injury caused by the construction of the line as quickly as possible without waiting for the court of arbitration.

Lord R. Cecil, K.C., submitted a clause on behalf of the landowners generally, providing that, in addition to the provisions incorporated in the Act with respect to compensation, "the company shall make compensation for all damage or loss of every description which may be caused to the owner, lessee, or occupier of any lands, house, or building by reason of the working of the railway, including the working of lifts and any other works in connection with the said railway, notwithstanding that no part of the property of such owner, lessee, or occupier is actually taken by the company, provided that all claims for compensation under this section shall be made within three years from the date of the opening of the railway for public traffic."

In reply to Lord Ribblesdale, counsel said he thought that subsidence arising through working would not be covered by the clause. As to subsidence during construction, they were content to leave themselves under the Lands Clauses Act.

Lord Ribblesdale asked whether, as the word "land" did not occur in Mr. Balfour Browne's clause, the owner of a garden with stonework and statuary, such as those of Lord Peterborough's and Pope's Villa, Twickenham, would be entitled to compensation for injury through subsidence.

Mr. Balfour Browne thought that such a case as that put by Lord Ribblesdale should be met, and he should have no objection to the inclusion of the word "land" in his clause.

Mr. Ram, K.C., asked the committee not to limit them to damage actually caused. They desired to have it safeguarded that they were entitled, at the arbitration hearing, to show prospective damage such as might reasonably be apprehended.

Mr. Littler and **Mr. Balfour Browne** opposed the landowners' clause, and contended that its adoption would absolutely prevent any tube railway from being made in London.

The committee adjourned the further consideration of the clauses.

TUESDAY, JUNE 3.

The committee heard further arguments of counsel in connection with the compensation clauses submitted by the promoters of the combined Hammersmith, Charing Cross, and City Railway and the landowners as the basis of the model clause to be inserted in all "tube" railway Bills.

Lord R. Cecil, K.C., on behalf of the landowners, said that, acting upon the suggestion of Viscount Knutsford, they had made certain alterations in their clause, which now read as follows: "In addition to the provisions incorporated herewith with respect to compensation for land taken or injuriously affected, the company shall make compensation to the owner, lessee, or occupier of any land, house, or building which shall be injuriously affected by reason of the working of the railway (including the working of lifts and any other works in connection with the said railway), notwithstanding that no part of the property of such owner, lessee, or occupier is taken by the company, as fully and to the same extent as if a part of his property had been taken by the company. Provided that all claims for compensation under this section shall be made within three years from the date of the opening of the railway for public traffic, and the provisions of the said incorporated Acts with respect to the settlement by arbitration of questions of disputed compensation shall extend and apply to and in the case of any such claim save that the amount of compensation payable by the company shall, if not agreed upon, be settled by a single arbitrator to be agreed upon by the parties, or, failing agreement, to be appointed by the Board of Trade; (2) an arbitrator under this section may, with the consent of all parties concerned, hear together any class or group of claims under this section." In deference to what he gathered to be the view of the committee, they had withdrawn the words "for all damage or loss of every description which may be caused," which appeared in their original clause.

Mr. Moon, K.C., representing the Great Northern and City Railway, said that if a liability such as that involved in Lord R. Cecil's clause was imposed on the promoters, there was grave doubt whether the capital could be raised. He suggested an extension of the operation of Section 68 of the Lands Clauses Act so as to include compensation for damage done in respect of the working as well as the construction of the railway.

Mr. Balfour Browne, K.C., for the combined companies, also opposed the amended clause.

The committee having consulted together,

The **Chairman** announced their decision as follows: The committee have decided to proceed on the basis of the last clause brought up by Lord Robert Cecil. They have decided to take the clause as it is drafted down to the word "railway." At this point they desire to make it clear that their intention is to make this apply to the railway so far as it is constructed in tunnel, and that it should not apply to the continuation of the line in the open. The actual words to carry out this intention we leave to be drafted. With regard to the words "as fully and to the same extent as if a part of his property had been taken by the company," the committee consider that at this stage of their proceedings it is of very great importance that their labours should not be indefinitely prolonged. The committee have decided to leave those words out, but they desire to lay down that, in arriving at this decision, they do not wish to prejudice their full discussion in the other House. The period for making claims will be two years instead of three years as provided in the clause. The rest of the clause down to the words "Board of Trade" will remain as it is, and the committee desire to insert here the words "and, subject as aforesaid, all the provisions of the Arbitration Act, 1889, shall apply to every such arbitration." The committee keep in Sub-Section 2 of the clause.

Lord Ribblesdale, who sat as a member of the committee for this special purpose, said he was armed with authority to represent and to act for his committee in that room, and he desired to say that he entirely concurred with the clause as laid down by Lord Windsor, and he wished it to be understood that the conditions he attached to the Bills which were passed by his committee were subject to the insertion of this clause.

Mr. Littler, K.C., hoped the committee would keep an open mind as to whether this clause should apply to already authorised lines or only to those that were asking for powers for the first time this session.

Lord Ribblesdale said that, speaking for himself, he laid it down that where a railway which had been authorised for some time and had done nothing got an extension of time, it must be subject to the insertion of the model clause.

The committee next proceeded to hear applications for special protective clauses in respect of particular buildings affected by the Piccadilly and City Railway.

The **Chairman,** in a discussion as to procedure, said it was a matter of the greatest importance in the public interest that these Bills should go to the other House at the earliest possible moment, and the committee hoped that every effort would be made to reduce the points of discussion before them.

The committee adjourned.

WEDNESDAY, JUNE 4.

The committee further considered the applications for special protective clauses in regard to particular buildings.

The promoters of the Brompton and Piccadilly-circus and the Piccadilly and City Railways agreed to accept a clause, in pursuance of the principle laid down by the committee, providing that, where two tubes run in close proximity under the same road, an owner could claim against the two railway companies. The claim was then to be referred to one arbitrator, who was to say which of the companies should pay such compensation as he might award, the hearing to be under the Arbitration Act, 1899.

The committee granted a special clause in the case of the Adelphi and Vaudeville Theatres enabling the owners of these theatres to appoint an engineer with power to inspect the carrying out of the work of constructing the line.

Mr. Littler, K.C., brought up a clause for the protection of the halls of the Middle and Inner Temples, the Temple Church, and the Master's house. He stated that an agreement had been arrived at with regard to the greater part of the clause, but the promoters objected to the following sub-section: "The company shall pay to the societies compensation for all damage and injury of every description which may arise to the societies' special buildings by or from the construction or working of the railway."

The committee passed the sub-section, but limited its operation to a period of five years from the opening of the railway.

Mr. Shiress Wills stated on behalf of the Albert Hall, that a clause had been agreed on with the promoters of the London United

Digitized by Google

Electric Railways, but, in view of the national character of the building, he asked for a further clause imposing on the company unlimited liability.

Mr. Coward, K.C., for the London United Electric Railways Company, pointed out that the line was 130ft. away from the Albert Hall, and that ample protection was afforded by the special clause that had been agreed on.

The committee said they could not accept the proposal for perpetual liability.

Lord H Cecil, K.C., applied for a special clause in the case of the Phillimore Estate, which extended from High-street, Kensington, to the summit of Campden-hill, and of which Sir Walter Phillimore is the life owner. What he asked was that the company should "indemnify the owner, lessee, and occupier against any damage to, or depreciation in the value of, their respective property which they may sustain through or by reason of the works of the company causing the drainage of underground water or springs."

The committee refused the application, and shortly afterwards adjourned.

THE SALFORD ENQUIRY.

On June 3, at the Salford Town Hall, his Honour Judge Parry opened the long-expected enquiry into the electricity undertaking of the Salford Corporation. According to the formal notice, evidence was to be taken: "(1) as to the building, etc., of the Walness works; (2) as to whether the aforesaid works could have been enlarged so as to use the machinery at present contained therein sufficiently to supply electric current for the necessary lighting and to run the tramways at the present time and for the next five years; (3) as to the total power provided in the Walness works and the new works, and if found to be in excess of the requirements, to go thoroughly into the matter and report to the Council as to who is responsible; (4) as to all matters appertaining to any specifications, tenders, or contracts in connection with the erection of Strawberry-road station; (5) as to any other matters that should be enquired into."

The Town Clerk (Mr. L. C. Evans) appeared for the Corporation. Messrs. W. Hunt, F. W. Wheatcroft, and C. R. Turner appeared on their own behalf. Mr. H. Galloway was in attendance on behalf of Messrs. Galloway, Limited, Mr. C. H. M. Wharton for Mr. Alderman Shaw, Mr. E. Desquesnes for Sir Richard Mottram, Mr. Hawkins for Messrs. W. T. Glover, Limited, Mr. T. W. Fox for Messrs. W. H. Bailey and Co., Mr. A. H. Dean for Mr. A. Haworth (a former member of the Borough Council), Mr. W. L. Hockin for Mr. Alderman Holland, and Mr. W. Cobbett for Messrs. Lacey, Clirehugh, and Sillar.

Before the enquiry opened Judge Parry elucidated two points, first, that privilege could be pleaded for *bonâ fide* statements if, subsequent to the enquiry, an action were brought against a witness; and, second, he could not compel witnesses to come to the enquiry.

Before the general points were gone into Mr. Hunt's observations with regard to such contracts were disposed of. Mr. Hunt stated that he did not make any charge of illegality or bad faith against Mr. Alderman Shaw or against Mr. Alderman Holland, and the judge relieved the counsel of these gentlemen from further attendance. Mr. Fox having no evidence to offer on behalf of Messrs. Bailey and Co. also withdrew.

Mr. Wheatcroft then opened his case with reference especially to Clause 3. He made a detailed statement in comparison of the electrical power installed by the borough for lighting and tramway purposes with that of Hamburg, to which town the Corporation had sent two deputations to gain information. While the requirements of Salford were not likely for many years to be more than one-third or one-fourth of those of Hamburg, the Salford installation amounted to 10,750 h.p. and that of Hamburg to 8,400 h.p. He went on to state that a sub-committee recommended that Messrs. Lacey, Clirehugh, and Sillar should be engaged to consider and revise specifications for work for 50 guineas. Ultimately the resolution of the General Committee was that they should be employed at £1,500. They were afterwards placed on a commission basis, and in March, 1899, they made a recommendation as to the generating plant that would be required. The committee had expected to receive a scheme much more moderate in cost than that previously drawn up by Mr. Turner. They received a scheme practically the same size, but under which the whole construction was to be rushed up and paid for within four years, whereas Mr. Turner's scheme was to erect the buildings as required. At Mr. Wheatcroft's request, the minutes were read relating to the provision of 16 Lancashire boilers. The longest period allowed for the delivery of these boilers was, he said, first 14 months. On his initiative this was made 18 months, and the words were added "if required.' At a later date, when he was not present, the committee rescinded the latter resolution and reverted to the original term of 14 months. Passing to Clause 4, Mr. Wheatcroft said that through the interference of certain parties in the latter part of 1898 the recommendations of the consulting engineer became "demoralised," and the official life of Mr. Turner not an enviable one. Mr. Turner informed him and the deputy-chairman and others that the representative of a certain firm had been to him, and pressure had been put upon him to include certain specifications for boilers in his scheme. Mr. Turner did not comply, and subsequently Mr. Turner was dismissed. Mr. Wheatcroft contended that on Dec. 7 a resolution was put on the agenda paper of the Council, which had not been passed by the committee, to the effect that the Electric Light Committee be authorised to arrange for the appointment of a consulting electrical engineer with reference to machinery and plant. The chairman had stated that he had been worried into putting this on the paper. (**Mr. Haworth,** who was then chairman of the committee, and was now present, here declared that this evidence was fabricated.) Judge Parry reminded Mr. Wheatcroft, who spoke of "sinister rumours," that the enquiry had to be into facts. Then the judge enquired as to what had been the specific wrong or ill done to the ratepayers.

Mr. Wheatcroft said that the chairman went and put this on the agenda paper because he was influenced by a gentleman who was not a member of the committee.

The **Town Clerk** contended that the matter actually did appear on the minutes.

Judge Parry said it was on the minutes in one form and not in another. He asked Mr. Wheatcroft whether he protested at the time about this matter, and he replied that he did so; what he suggested was that it was intended to appoint an engineer to upset the scheme of Mr. Turner. He thought the chairman in this matter had broken faith with the committee.

On the resumption of the enquiry on the 4th **Mr. Wheatcroft** continued his statement. He suggested that the consulting engineers employed by the Corporation were weak advisers. He thought undue preference was shown to a firm of boilermakers.

Mr. Dequesnes produced a letter from **Mr. W. M. Mather,** in which he said that however satisfactory an electrical engineer the Corporation might have, having regard to the extreme importance of the matter, Salford was really departing from the practice of other municipal corporations in not seeking advice from well-known authorities, and his firm would not tender on a particular specification.

Mr. Wheatcroft admitted that, so far as Sir Richard Mottram was concerned, his understanding was now modified. He was unaware till that day of this letter, yet he thought Sir Richard ought not to have attended a meeting of the committee when they considered certain boilers, nor should Mr. Haworth have asked Messrs. Galloway to tender. He had nothing to say against Messrs. Galloway as a firm.

Mr. Turner also said he had nothing to say against the firm.

Judge Parry said that such charges as were made appeared to be against Sir Richard Mottram personally, and he would give evidence. He relieved Mr. Galloway from attendance till Saturday. With regard to a charge by Mr. Hunt against the firm, nothing would be heard before them.

Mr. C. L. Turner then said he entered the service of the Corporation in October, 1894, and on the completion of the Walness-road station he became manager, when in March, 1897, the Council elected a standing Electric Light Committee. He was appointed borough electrical engineer, in which office he continued till May, 1900. He complained that he had not been supplied with certain information which he had asked for from the town clerk.

The **Town Clerk** read a letter from Messrs. Lacey, Clirehugh, and Sillar showing that he had applied to them for the information in question. They had replied complaining of vague and damaging charges, and expressed their readiness to afford to Judge Parry any information on specific points which he might require.

Mr. Turner rejoined that what he had asked for was Corporation property, and not that of the firm named.

Judge Parry said he would consider the matter later.

Mr. Turner, continuing, said as to Clause 2, the Walness works could not be enlarged, and if they had been the cost in cables would have been £15,000 more. On Clause 3, he considered the Corporation had now 3½ times more plant than was required. The estimated cost at Strawberry-road alone, including cables, was approximately £400,000. He did not say the amount of work put in for trams was so much in excess of the requirements as that for lighting, and he thought the two ought to be separated. At least half of the capital cost might have been left over for a future date.

Mr. Cobbett did not admit on behalf of his clients that the plant was 3½ times too big, and the plant Mr. Turner desired would have been 11½ times too large.

At this stage the enquiry was adjourned till next morning.

FORTHCOMING EVENTS.

FRIDAY, JUNE 6.

Royal Institution.—At 9 p.m., Sir Benjamin Baker on "The Nile Reservoir and Dams."

FRIDAY, JUNE 13.

Royal Institution.—At 9 p.m., Mr. G. Marconi on "The Progress of Electric Space Telegraphy."

Physical Society.—From 3.30 to 6 p.m., visit to the National Physical Laboratory, Bushy House, Teddington. Trains leave Waterloo (south station) at 2.36, 3.14, 4.15; and Waterloo (Windsor line station) at 2.40, 3.17, 3.40.

APPOINTMENTS VACANT.

Assistant, for India, versed in electrical (and with a good knowledge also of mechanical) engineering, 300 rupees per month. See advertisement.

Manager and Engineer to take charge of South Wales branch for contractors. See advertisement.

Calarashi-Stirbein (Roumania).—The Municipality invite tenders for the installation and working of electric lighting for 35 years. Tenders by June 13.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXVII., bound in blue cloth, gold lettered price 8s. 6d.

PEACE AND ITS TROUBLES.

Since our last issue, not only the British Empire, but the world has welcomed the realisation of peace in South Africa. It is now time for business men to turn their attention to what will happen as soon as the ordinary avocations of life commence in earnest in what has been the seat of war. For the past two or three years Great Britain has been the most vituperated nation in the universe. For a long time it was difficult to see why this should be so; and especially when it is understood that we have long been looked upon as a nation of shopkeepers, and not as a nation who revel in aggressive warfare. It seems, however, that the peaceful tendency of our policy, coupled with the justness of our rule, are the principal reasons which have drawn upon our heads the calumny of competing nations. A German paper sums up the matter very tersely, as will be seen from the following extract taken from the *St. James's Gazette* of Wednesday last:

"According to the *Börsen-Courier*, German merchants interested in the export trade to South Africa have long reckoned upon an increase of business consequent upon the declaration of peace. The *Rheinisch-Westfälische Zeitung* takes a somewhat different view, and observes: 'For us Germans the final surrender of the independence of the Boers is a heavy blow. Not only on political grounds is the situation serious, seeing that as a South African Colonial Power we shall in future be face to face with a compact and gigantic South African Power which is entirely English, and which is no more menaced by a Boer State. . . . We shall also have to suffer from commercial exclusion. England is now supreme over the Boer Republics, and will consequently have a vast quantity of custom to dispose of. All the railways will be built by England; all German monopolies, like the famous German dynamite monopoly, will be abolished; English, not German, officials will be employed; industry subject to English influence will be preferred; and English goods, English imports, will be favoured by the customs arrangements. In a word, a portion of the earth is once more lost as a market for the products of German labour and is secured for our English rival.'"

The intense selfishness of this view will be realised when the question comes to be more clearly examined. In this question of business our Colonial possessions are quite as free to other nations as to the Motherland. This is not only unfair, but unjust; but it passes the bounds of comprehension of those who look at the matter clearly. Take this latest instance of increase in British territory. Dealing with it only from a monetary point of view, it has cost at least two hundred millions of money, and for the moment the nation is saddled with an increased annual interest payable, owing to the war. Part of this interest may, no doubt, in the future be borne by the new colonies, but that will not affect our argument. The amount of money expended may be likened to the paper capital of any company, which bears interest, but does not exist and never has existed in the shape of working capital. Every business man clearly understands the added difficulties to the success of a company which possesses a large amount of watered capital. The products of the company cannot be sold so cheaply, or they are not produced so perfectly, as would be the case if such excessive capital did not exist. Great Britain is in a similar position. If it admits free competition from all other nations, it has to face such competition heavily handicapped because of the burden imposed by this expenditure upon it, and therefore cannot so easily or so satisfactorily compete with those manufacturers and merchants who have to bear none of the liabilities. It seems to us, therefore, that in fairness and justness to our

Digitized by Google

own people some method ought to be found in order to place competitors upon the same footing as ourselves; and in this we are asking for nothing exceptional, but merely a fair field and no favour. If England and Englishmen cannot hold their own when all other things are equal, it is time the nation took a back seat; but we do not think that this has yet come, nor do we think our manufacturers and merchants unable to completely hold their own when the disabilities on all sides are equal. How exactly the burdens are to be shared by those who propose to do business in South Africa, it is not our province to say. We have merely to point out that the burden exists, and it should be so apportioned that it does not handicap this country too heavily. Let us take a word or two from our German contemporary: "All the railways will be built by England." That is a very wide statement, and of doubtful accuracy, and especially so if foreign merchants who have taken none of the risks, and upon whom lie none of the liabilities, are permitted to compete without restraint with those of the Motherland. The industry with which we are more intimately connected with is one which ought to hope for great development, not only in the new South African provinces, but over the whole of South Africa, now that peace is assured, and the argument we have used above applies to this industry as much as to any other. It is to be hoped, therefore, that politicians will consider the exact condition of matters, and will act clearly and justly to secure what we have termed a fair field to the British community, and not give over the land into the hands of those who have stood by and neither shared the dangers nor the costs, but who are quite ready to take all the profits.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

AIR-PUMPS.

SIR,—With your kind permission I should like to point out a few of the most glaringly misleading statements made by your correspondent "T Square" in reply to Question No. 478.

The correspondent responsible for this question is evidently in search of information, having taken the trouble to make a couple of drawings to scale, and it seems a pity that he should be misled.

To begin with, "T Square" states that with a jet condenser a vacuum of "26" certainly could not be obtained. This statement is quite erroneous, as there are scores of jet condensers giving a vacuum of 27in. in Lancashire alone.

Secondly, "T Square," in computing the volume of the air-pump, fails to take into account any air to be dealt with by the pump except such as "leaks in."

Thirdly, the diameter given for the air-pump barrel—viz., 11½in.—gives a valve area through the bucket 50 per cent. less than is necessary to obtain decent results.

Fourthly, "T Square" informs us that "if the air-pump is double-acting, we need only make it half the size." As a matter of fact, no double-acting air-pump can be made to do the work of a well-designed single-acting vertical air-pump twice its capacity.

Indeed, sir, the whole article, including the sketch of a *horizontal* jet condenser, shows a charming innocence of things mechanical. Now, sir, there are hundreds of your readers who are engineers in addition to being electricians, and who will endorse every remark written above.

I should recommend the correspondent who sent you Question 478 to consult some standard work, such as Seaton's "Manual of Marine Engineering" or Hurst's "Hints on Engine Design."—Yours, etc.

E. COSGRAVE.

[N.B.—Would it not have been better if our correspondent had answered the question himself.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

487. Give details of the best method of regulating the direct-current E.M.F. of a rotary converter.—T.

488. Give a full description of the proper tests which should be applied to girder section steel tramway rails, say 100lb. per yard; also what results would be considered satisfactory from such tests.—G. W.

[N.B.—Will Mr. H. Taylor kindly forward to us his address.—ED. *E. E.*]

ANSWERS.

Question No. 481.—In a central station in which both batteries are temporarily disconnected, a 350-kw. machine and two 70-kw. steam balancers are on load (lighting and power) connected on + and − respectively of a three-wire system, the 350-kw. being across the outers, with its field excited from the negative 'bus bars. A slight load comes on to the − side, causing the volts on that side (−) to drop slightly; as the big machine and balancers are fully loaded up, another machine is ordered to be got ready. Before this can be done the volts on both sides suddenly drop to zero, and a total shut down is the result. How can this be explained, and could the shut down have been avoided? I might mention that the two 70-kw. steam balancers were self-exciting two-pole machines.

Best Answer to No. 481 (*awarded* 10*s.*).—The probable cause of the occurrence mentioned is the instability of the fields of the balancers. Very likely these are double-voltage machines giving any voltage between, say, 280 and 220 volts (supposing the station voltage to be 440 across the outers) by means of shunt regulators, the former voltage being employed when charging the cells and the latter when acting as balancers. When working at the lower voltage, as in the case under consideration, the magnet iron of the machines will be very far from saturated; thus, supposing the density in the iron to have a usual value of about 15,000 C.G.S. lines per square inch at the higher voltage, the figure for the lower voltage would only be about 12,000, and this value would lie on the straight part below the bend of the permeability curve for ordinary wrought iron or even cast steel. Any shunt dynamo working at this low density would be in great danger of losing its field—*i.e.*, of its volts dropping suddenly—if the machine is slightly overloaded or if the speed falls slightly.

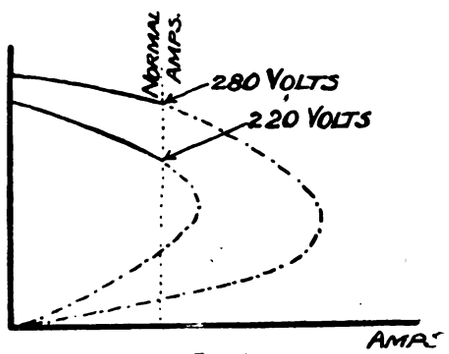

FIG. 1.

The way in which the characteristic (volt-ampere) curve of a shunt machine differs at the high and the low voltages is shown in Fig. 1. At the high voltage the machine will stand two or three times its full-load current before reaching the unstable point A, whilst in

Digitized by Google

the case of the low voltage the unstable point B is reached with only a slight overload. When an additional load is thrown on to the negative side of the system, as described in the question, most of it naturally falls on the negative balancer, and this being in an unstable state, the slight addition, aided, perhaps, by a drop in speed due to the sluggish action of the governor on the negative balancer engine, would cause the unstable point on the curve to be reached. The balancer volts would then rapidly fall to zero, and its armature would become a short-circuit across the negative side of the system. At the same time the volts across the shunt of the 350-kw. generator, which is excited off the negative side, would fall and cause this generator also to lose its field. Even if it were excited across the + side or across the outers, it is highly probable that the excess load thrown on the main generator, due to the practical short-circuiting of the negative side by the negative balancer, would alone be sufficient to cause loss of field. Finally, the + side balancer, being practically short-circuited by the other two armatures, also loses its field. Even supposing that the balancers are not double-voltage machines the above occurrences might take place, but this is not very likely unless the machines are quite wrongly designed or unless the sudden increase in load is a large one.

With regard to the prevention of the recurrence of the accident, the simplest remedy consists in separately exciting all the machines (or, at least, the balancers) off the battery, even where the latter is not connected to the supply circuit, for separately excited dynamos are not troubled with unstable points in the same way that shunt ones are. A small auxiliary dynamo might be used for separately exciting the machines in place of the battery. If, however, this plan is not feasible, owing to the battery being wholly discharged or out of order, and no auxiliary dynamo being

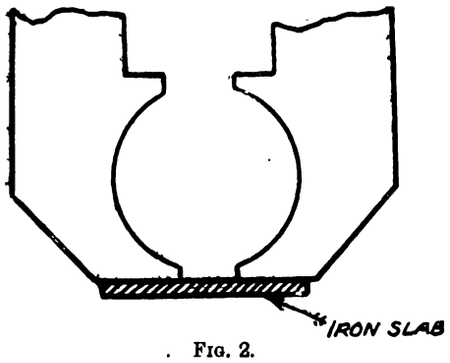

FIG. 2.

available, the balancers could be rendered more stable by fitting them with removable magnetic shunts (Fig. 2), which would be in use at the low voltage only to produce the volt reduction (from 280 to 220) by saturating the magnets in place of the usual method of reducing the exciting ampere-turns by means of a resistance. The magnetic shunt might be arranged to produce most of the volt reduction, and the field regulating resistance might be used for fine adjustments only. This arrangement would have the effect of making the machines, if anything, more stable at the low voltage than at the high, and there would be no likelihood of loss of field occurring at either voltage.—Q.

Answer to No. 481 (*awarded* 7*s.* 6*d.*).—The cause of the shut down mentioned by "R. M." would be due to the exciting current of the 350-kw. set being supplied from one side of the three-wire system (Fig. 1), instead of being connected across the outers (Fig. 2), and the drop in pressure due to the increase of load occurring on the side supplying this exciting current. If we assume a drop in pressure of, say, 10 volts in 200 between negative and neutral, it will mean a drop of 5 per cent. across the field of the 350-kw. set: but had this 10 volt drop occurred when field is connected across the outers, it would only mean a drop of 2½ per cent. The drop of the assumed 10 volts across the field of the large set would cause its voltage to drop considerably, the result being that the two balancers in series will reverse the direction of the current through the armature of the 350-kw. set, and thereby themselves become considerably overloaded, and, being shunt machines, will lose their volts. On the other hand, if the large set had been excited across the outers, it would not have been to any great extent affected by the drop on the negative side. To avoid the complete shut down, the rheostats in fields of negative balancer and large set should be opened up so as to keep proper pressure, but if all stops are cut out and speed of machines cannot be increased, then the most unimportant circuits on the negative side should be switched off until another set is coupled to bus bars, then

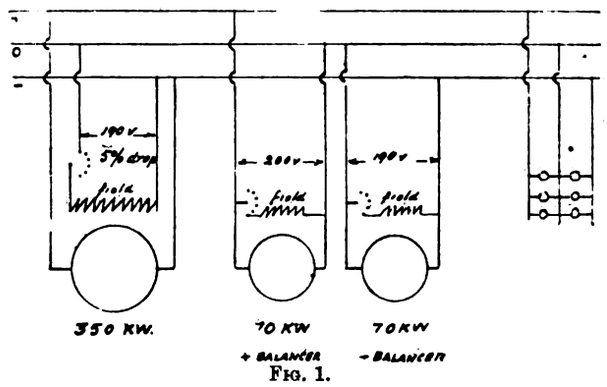

FIG. 1.

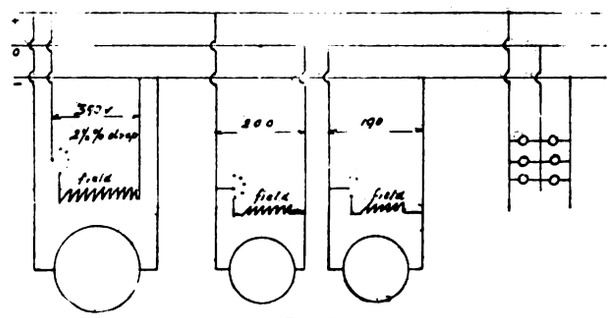

FIG. 2.

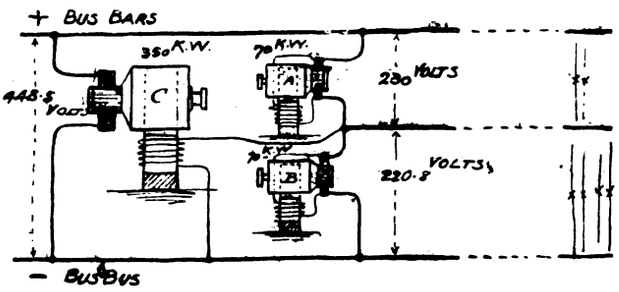
the circuits can again be switched in, and the balancers will only have to deal with the out-of-balance load. It would always be better to keep the battery connected up, as it is such handy plant to deal with out-of-balance or sudden load.—S. F. R.

Answer to No. 481 (*awarded* 5*s.*).—Let (C) represent the 350-kw. machine, and (A) and (B) the smaller machines on the (+) and (−) sides respectively; all



machines being steam driven. As stated in the question, the large machine and the two small machines are fully loaded up when there comes a small extra load on the (−) side. The following is the sequence of events:

1. The volts on (B) drop, let us say, by 2 per cent.—*i.e.*, from 230 to 225·4 volts.
2. The *fields* of both (B) and (C) are thereby reduced by, say, 1 per cent., depending on the state of magnetic saturation.
3. The *volts* of (B) are further reduced by 1 per cent.; ditto (C); due to (2).
4. The *field* of (B) is further reduced by, say, ½ per cent.; ditto (C); due to (3).
5. The *volts* of (B) are further reduced by ½ per cent.; ditto (C).
6. The field of (B) is further reduced by ¼ per cent.; ditto (C).
7. The volts of (B) are further reduced by ¼ per cent.; ditto (C); and so on.
8. So that if the fields of (B) and of (C) were in precisely the same state of saturation, the ultimate voltage drop on

Digitized by Google

(B's) armature would be, say, 4 per cent., and on (C's) armature, say, 2 per cent.

Now, 4 per cent. on 230 volts is the same as 2 per cent. on 460 volts, so that no relative shift of load occurs between generator and balancers under these conditions.

9. But, *if (C's) field be more susceptible than (B's) field*, we may easily get, say, 2½ per cent. drop in (C's) volts for 4 per cent. in (B's) volts.

10. Now, 2½ per cent. on 460 – volts = 11·5 volts, and 4 per cent. on 230 – volts = 9·2 volts, giving an excess of voltage on the balancer system of 2·3 volts, (A's) volts volts remaining at 230.

For $C = 460 - 11{\cdot}5 = 448{\cdot}5$ volts;

$$A + B = 230 + (230 - 9{\cdot}2) = 450{\cdot}8 \text{ volts.}$$

11. Therefore, with the *commencement* of the fall in the volts of (B), the tendency is for (A) and (B) to snatch away all the load from (C).

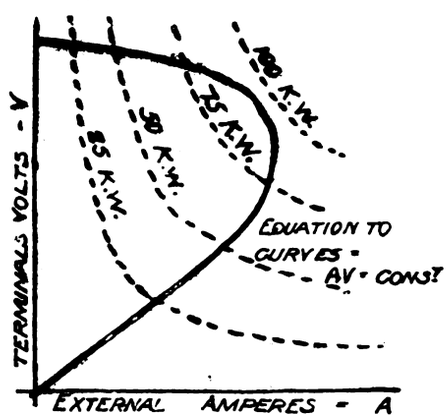
12. This would tend to put on (A) a load of three times its normal full load, and on (B) of more than this.

13. Consequently the drops in (B) and (C) would be largely augmented above those considered in paragraph 8, with the result that the two balancers would still further overpower (C), till they were pulled up and lost their fields and C's field together with them, the "minimum" automatics being also thrown, a shut-down ensuing.

Remedy.—Put (C's) field across the outers.—A. M. T.

Answer to No. 481 (*awarded* 5*s.*).—It is well known that, owing to the characteristic relation between external amperes and terminal volts in a shunt machine, the effect of overloading the generator is to cause the excitation to fail and the machine to cease work. This is the probable cause of the failure described.

The course of events may have been as follows: The slight increase of load on the negative side may have made the load on the negative balancer a little in excess of its limit of stability, and consequently this machine failed, since its exciting coil was placed across the machine terminals. This produced three effects: the system became unbalanced (the other balancer probably passing an excessive current in an attempt to restore balance), a part of the load was transferred from the steam-driven negative balancer to the main generator, loading this up to or beyond its limit of stability (for it was, before, fully loaded), and the armature of the magnetic balancer, having now no back E.M.F., forms a short-circuit between the negative and neutral bus bars. All the machines being shunt wound, it is an open question whether the positive balancer failed through excessive load and the main machine, running on two dead armatures in series across the bars, also failed; or whether the simple increase of load on the main set caused it to fail in the first instance, the remaining balancer shutting down afterwards.



The way to have prevented the accident was to have immediately strengthened the field of the negative booster if this were possible—*i.e.*, if all shunt resistance were not already withdrawn—in order to raise the limit of stability of the machine. If this could not be done, the best course would have been to pull off some of the load on the negative side by switching out one or more of the feeders until another generator had been put in. This would have to be done very promptly, however, in order to save the balancer, as a field once weakened in this way is very quickly overcome by the armature reaction. The mishap shows, by the way, the utility of a "floating" battery in a traction system to take care of sudden variations of load and the inadvisability of leaving too small surplus generating power at any time.—S. A. J.

Question No. 482.—Describe exactly how you would calculate the load factor of a lighting and traction station respectively, and in what way would the conditions for a maximum load factor differ in each case?

Best Answer to No. 482 (*awarded* 10*s.*).—The calculation of the load factor for a station which is in operation is comparatively easy. All we have to do is to take readings, say, every half-hour throughout the day, of the total kilowatts being generated by the machines and then plot these readings. We shall then get curves somewhat as in Fig. 1, according to the nature of the load on the station. Thus the load curve of a station on a private lighting load only would be represented by a curve something like A in Fig. 1.

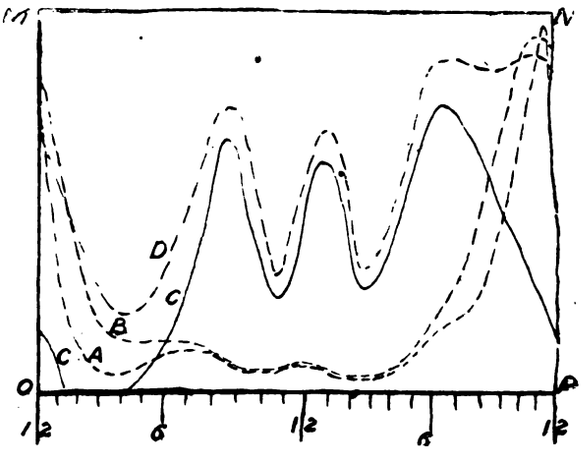


FIG. 1.

B represents a combined public and private lighting load, C is a traction load, and D a combined lighting and traction load. The shape of the curves hence depends very greatly on the special conditions of each case, and also on the time of the year and the weather, and in a mixed system on the percentage of the constituents. Let O M represent the maximum rate of output of the station in kilowatts. Then the area of the rectangle O M N P represents the maximum possible output of the station in kilowatt-hours during a day; also the area below the load curve represents the actual kilowatt-hours which have been generated. This can easily be found by a planimeter. And the load factor

$$\text{L F} = \frac{\text{energy generated}}{\text{maximum possible}} = \frac{\text{area below load curve}}{\text{area of rectangle O M N P}}.$$

To estimate the probable load factor of a station which has not yet started operations is more troublesome, and can only be done approximately. A careful canvass of the district must be made, and an estimate made of the approximate power which each intending customer will use at each hour of the day. These amounts must be added up and the load curve plotted as above. The total cost per kilowatt-hour generated may be divided up as follows: (*a*) coal; (*b*) oil, waste, water, and stores; (*c*) wages of workmen; (*d*) repairs and maintenance; (*e*) rents, rates, and taxes; (*f*) officials' salaries, legal and insurance expenses; (*g*) interest on capital and depreciation of plant. Now, the higher the load factor the greater the output of a given plant, hence items (*b*), (*c*), (*d*), (*e*), (*f*), and (*g*) are at once reduced, since although the actual sums of money devoted to these purposes remain about the same, the kilowatt-hours produced by them has gone up. Also (*a*) will be improved, since the plant will be working more efficiently as it is running nearer its full load. The effect of load factor on the cost per kilowatt-hour when generated is given in the following table by Mr. Philip Dawson for stations of not less than 2,000 kw. capacity. These total costs include all the items except the last (*g*).

The average load factors actually obtained in station work in England are about as follows: private lighting, 10 per cent.; public and private lighting, 12 to 15 per cent.; tramways, 15 to 20 per cent.; tramways and

Digitized by Google

lighting, 20 to 25 per cent.; tubes and large power distribution stations, 25 to 30 per cent.

Load factor. Per cent.	Coal at 10s. per ton (*a*).	Total cost per unit generated.
10	·6d.	1·0d.
15	·5d.	·78d.
20	·4d.	·56d.
25	·35d.	·45d.
30	·32d.	·4d.
35	·3d.	·35d.
40	·26d.	·33d.
45	·25d.	·3d.
50	·24d.	·28d.
60	·22d.	·25d.
70	·19d.	·24d.
90	·16d.	·23d.

In order to have a good load factor we must try to comply with the following conditions: (1) Our station must contain just sufficient plant to be able to tackle the peak of the load when giving its maximum output. If, however, the peak is very sharp and high, we may meet it by overloading the plant for a short time. If we carry this too far, however, we may find ourselves unable to cope with any extra high peak which may at any time be caused by some particular set of circumstances (2) We should try to keep the peaks of the load curve as flat as possible—*i.e.*, the maximum demand lasting as long as possible. The most usual way of flattening out the peaks on the generator load curve is by the use of storage batteries. The cells are charged up when the load is light, and are then used to relieve the generators when the peak comes on. It is true that we lose some energy in the cells, but the generators are working with a higher mean and a lower maximum load—*i.e.*, with a higher load factor—and so they have a higher mean efficiency. We are thus enabled to use smaller generators, engines, and boilers, or fewer of them, but against this has to be put the cost of the batteries. As, however, the price of a battery is much less than that of engine and boiler plant, which would take the peak as well, we are enabled to cut down the first cost of plant considerably, and hence item (*g*) as well. Unfortunately, however, batteries are rather unreliable, and need a lot of attention; many engineers prefer to do without them if possible.

Something may be done in the way of improving the actual load factor of the station output by means of special tariffs to encourage customers to keep their maximum demand as low as possible. The usual systems of charging in vogue at present are as follows: (1) *flat rate*, comprising those in which a single price per unit is charged for lighting, or a discount is given not based on the "load factor value" of the customer; (2) *sliding scale*, including the Hopkinson system and discounts based upon the number of units consumed per lamp wired, etc.; (3) *maximum demand*, in which the price per unit charged varies directly as the maximum load taken, the lower the maximum the lower the price per unit.

The following results have been found by Mr. A. Baker by comparing these three systems on a large number of purely lighting load stations in England:

	Load factor. Per cent.	Year's lamp increase. Per cent.	Price per Kw.-hour.
Flat rate	12·57	25·2	1·92d.
Maximum demand	11·78	36·3	1·79d.
Sliding scale	11·85	29·13	1·8C3d.

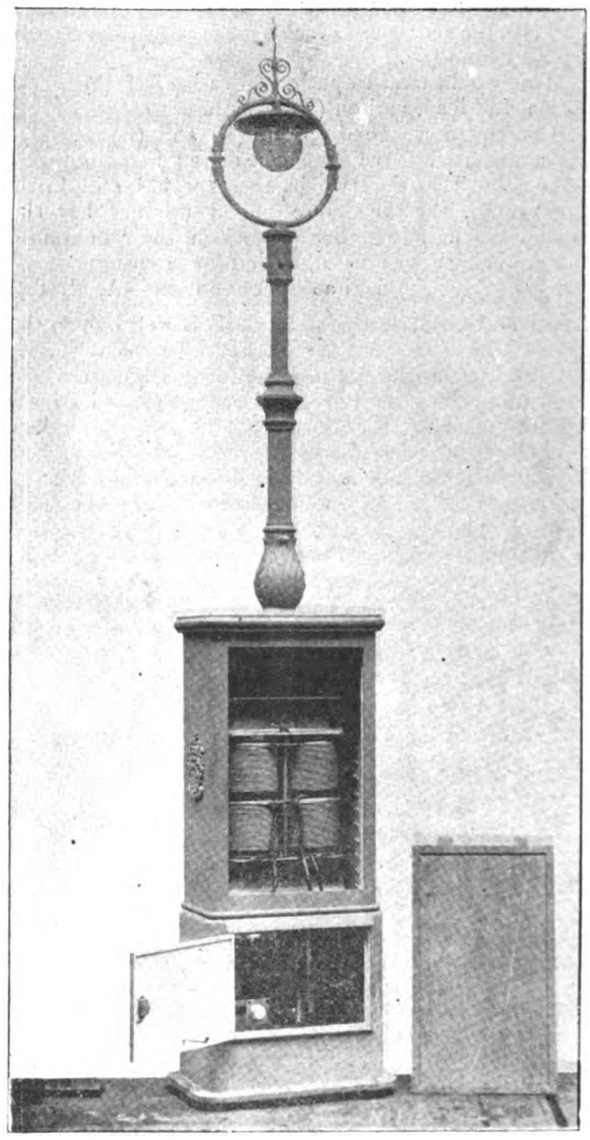
From this it appears that on the average the maximum demand system attracts the most new customers, but the flat rate gives the best load factor. We can, however, only take this table as indicating roughly the tendency of the different systems. In Canada the maximum demand system has been found to greatly improve the load factor.

It also usually improves the load factor to have several different kinds of load on the station. Thus any mixture of traction, lighting, and motor loads will have a better load factor than any one separately, since the maximum loads on each occurs at different times of the day. An additional motor load during the day is also a good thing in both traction and lighting stations, and especially good terms can be offered if the customer agrees only to take power during the light hours of the day. Something might also be done in the case of lighting stations to encourage the use of electricity for domestic purposes, such as heating and cooking.—T. SQUARE.

TRADE NOTICES AND NOVELTIES.

Wilkinson's Street Transformer Pillar and Lamp Standard.

We illustrate herewith one form of the Wilkinson's patent combination of a lamp column with an overground transformer box, which are being manufactured by Messrs. John Fowler and Co., of Leeds and London. The details of the apparatus are so clear that a full description is hardly necessary, but we may mention that all the pillars are designed to contain a 50-kw. transformer. Of course, a smaller transformer can be used when the works are first started, if it is so desired, in order to keep down the first cost or the hysteresis losses. In the lower compartment there are contained the high and low tension switchgear and fuses, which can be actuated when the door in front is opened. A similar door at the back gives access to a cable connection. On the low-tension side provision is made for four low-tension distributing circuits. To aid in getting the transformer into



The Wilkinson Transformer Pillar and Lamp Column as made by Messrs. John Fowler and Co.

and out of the case, a number of rollers are arranged in the support for the transformer. The pillars are efficiently ventilated and thoroughly protected against rain. In fact, these boxes contain every detail that is required for a permanent arrangement of a transforming station above ground at a much less cost than is necessitated by the ordinary sub-station.

Electric Cranes.

For operating travelling cranes the electric motor has no rival which can be at all seriously considered. This fact is clearly shown by glancing through the electric crane list of Messrs. Royce, Limited, of Manchester. The major portion of this is devoted to illustrations of cranes already at work, and to descriptions and specifications of the numerous different types of electric cranes manufactured by the firm. These vary from the large Goliath crane, illustrated herewith, which was erected by the company in the goods yard of the Great Central Railway at St. Marylebone, down to small jib cranes used for working in shops to facilitate the rapid handling of materials. The advantages which electricity has for this class of work are exceedingly numerous, and a travelling crane equipped with three motors, one for each motion, is a means of saving a huge sum per annum in establishment charges in large engineering works. Not only is the crane able to do this work quickly, but there is the

Digitized by Google

resultant advantage that there is not the waiting for the use of the traveller. For large outdoor work, such as that of the Goliath in

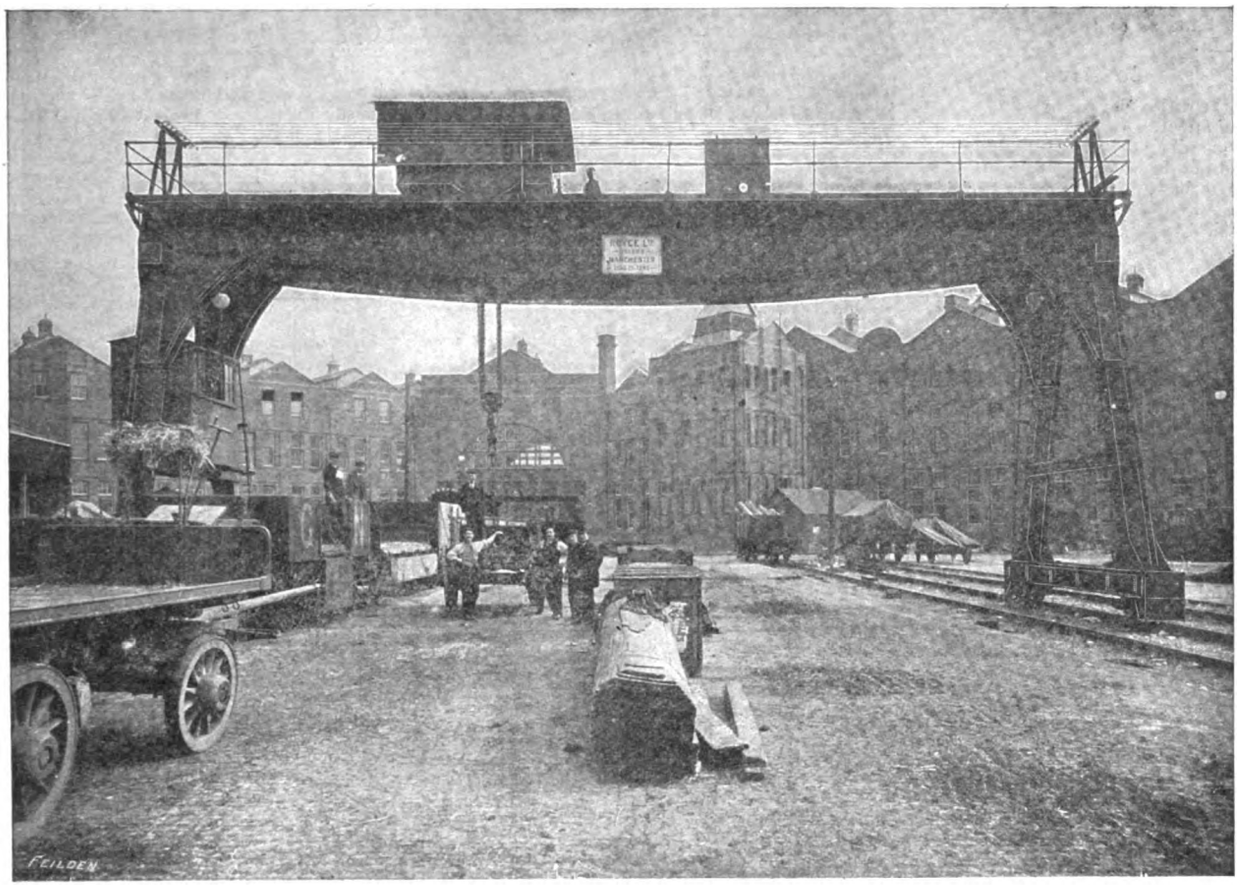


FIG. 1.—25-ton Goliath Crane, by Messrs. Royce, Limited.

Fig. 1, there is the great additional advantage that there is no interval required in starting up, as is the case with steam-driven cranes, in which a boiler fire has to be lighted and steam got up In Fig. 2 we give an illustration of a 20-ton electrical crab made by this firm. In connection with the brake on this, which is worked from the solenoid

Special Track Work.

Messrs. Askham Bros. and Wilson are noted for the excellency of the special track work for tramway purposes. The need for this class of goods in connection with tramways has been much more keenly felt since the introduction of electric traction, involving heavier cars

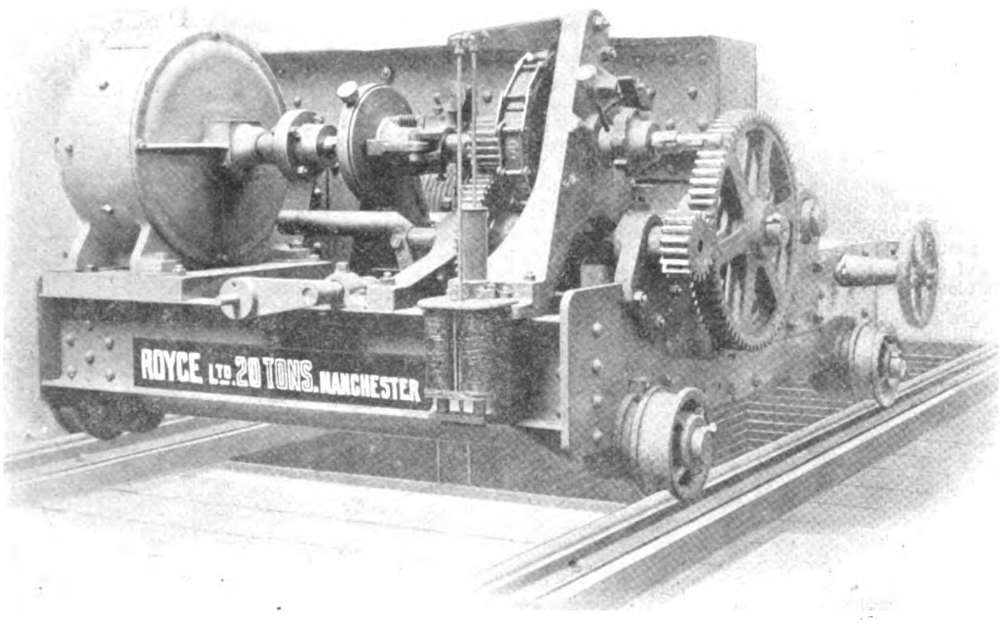

FIG. 2.—Electrical 20-ton Crab, made by Messrs. Royce, Limited.

seen in the foreground, a dashpot is provided to prevent the brake being too suddenly put on when the current is interrupted. This oil dashpot prevents the kinetic energy of the motor armature unduly straining the gearing, as would be the case were the brake jammed on while the motor was still going at full speed. From the specifications given elsewhere in the catalogue in question one sees that the firm take great care in selecting the most suitable materials for the various parts of their cranes.

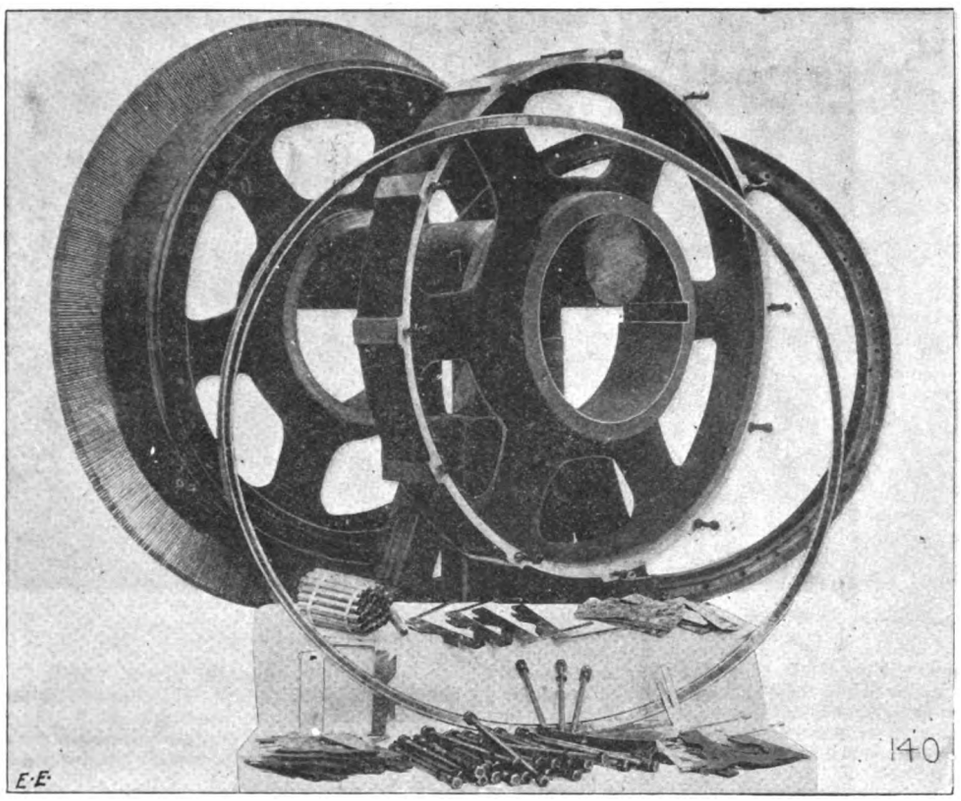
moving at higher rates of speed. The firm in question have specialised in the department, and make a practice of erecting all the special work ordered from them in their own shops before delivery. The advantage of this course will be obvious to all engineers, as it avoids the costly alterations which otherwise may have to be carried out on the road. It also tends to reduce the time very largely during which

Digitized by Google

the streets have to be left opened out, and in this way saves great inconvenience to the public. The recent list issued by Messrs. Askham Bros. and Wilson of their special track work should find a place amongst the literature of all tramway engineers. It contains a number of illustrations of work previously carried out by the firm, from which useful hints as to the design of special work in other towns can be gleaned.

Continuous-Current Generators.

In the earlier days of electrical engineering the details of construction of armatures and commutators were looked upon as trade secrets to be guarded with the utmost care, in order that rivals in manufacture should not derive benefit from the same. In this respect times have changed, but it is not often that so much technical information is given away as appears in the illustrated book recently issued by the English Electric Manufacturing Company, of Preston. The book, which is entitled "Continuous-Current Generators," is exceedingly well illustrated, and discloses practically every detail in the manufacture of the machines in question. In this case there is no price-list or catalogue of sizes included, and the book deals only with the details of construction. We have recently published a short description of the two large dynamos made by the above firm, and supplied through their sole agents, Messrs. Dick, Kerr, and Co., to the Bolton Corporation. There is, therefore, no need to again give the details we then published, but through the courtesy of the firm we are able to give the accompanying block, illustrating the various parts which go to form a commutator of one of these direct-current generators. Although the block may not be quite so clear as the photograph from which we had it prepared, the method of construction can be clearly seen. For instance, in the commutator sections the design is such that the individual segments of copper are supported both against centrifugal force and against a blow which would tend to make one bar recede inwards. In the book before us the other items of construction, such as the armature windings, the brush gear, the building up of the armature core, are illustrated in much the same way. We presume that the object the firm have in circulating so much information is to bring the excellency of their manufactured articles to the notice of those engineers who have orders to place, and we know of no better way of influencing business.



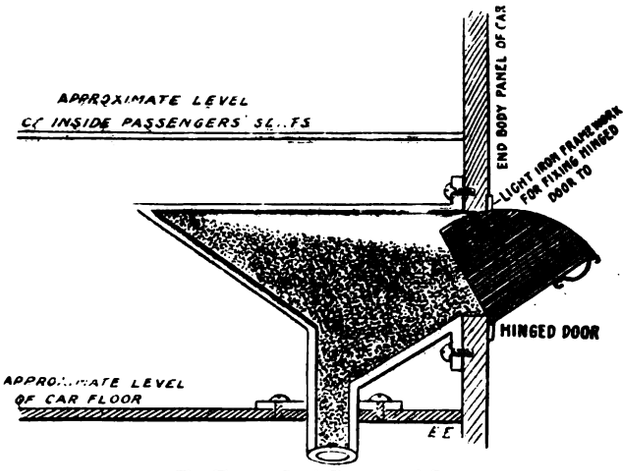
Complete Commutator and Commutator Parts as used by the English Electric Manufacturing Company.

Electroliers.

The Edison-Swan United Electric Lighting Company have recently issued a small list of their latest designs in electric light fittings. The main feature which a general perusal of the same gives is that the modern tendency is towards simple designs with an oxidised silver finish rather than the old florid brasswork. Hammered ironwork also figures prominently in the list in question, while a good number of the fittings have an armour-bright finish. From the illustration we should say that a visit to the showrooms of the company to see these new types would be well repaid.

The Thomas Sand-box for Tramcars.

We illustrate herewith an arrangement of a sand hopper or box on the tramcar which has been designed by Mr. H. N. Thomas, the engineer and manager of the Huddersfield tramways, and for which he has applied for patent protection. It is from Huddersfield that one would look for improvement in connection with the sanding gear in connection with tramcars owing to the exceedingly hilly nature of the tramway routes in that town. It is not in this case a question of heavy grades for a few yards only, but of long hills, which give rise to excessive speeds and disastrous accidents if once a tramcar gets out of control. As a consequence, a good deal more sand is required than is the case on ordinary lines, and the need arises of introducing more sand into the boxes in the course of the day's run. With the ordinary type of box this involves the lifting of the cushions or the seats of the car. In view of the accident which happened some years ago with a runaway steam tramcar in Huddersfield, a sudden request on the part of the conductor to the passengers to stand up so that he may refill an empty sand-box is not reassuring, and apt to cause a slight panic. It will be seen from the illustration that the hopper designed by Mr. H. N. Thomas avoids this risk, and at the same time renders the refilling operation much more simple. In this case the hopper sand-boxes are refilled through the panels at the ends of the car by either the conductor or the driver while standing on the end platforms. This construction has a number of indirect advantages quite apart from the details of design, which give great strength and rigidity to the sand-box. One of these advantages is that the sand is not spilt inside the car or over the motors, where it is likely to cause inconvenience to the passengers and damage to the running gear; also, there will be no sand spilt on the cables used to connect up the motors to the controllers. Mr. Thomas informs us that the first cost and maintenance of the new type of sand-box is low, and that they are more durable than the older types. The hinged door through which the sand is introduced is made to match the rest of the car, and secured in position with a fancy scroll brass handle. The door is, therefore, hardly noticed when inspecting the car, and yet is exceedingly handy to the driver or conductor. It may interest our readers to know that, with the increase of load on the tramways works at Huddersfield, Mr. Thomas has already got his cost of generation per unit down to ·345d., and that as the daily output will shortly be increased, this figure must not be looked upon as being at all final as far as lowness of cost is concerned.



The Thomas Sand Hopper and Box.

Fittings	22	17	0
	£5,197	17	7

Units consumed during year, 241,534.

TAUNTON ELECTRICITY ACCOUNTS.

In the accounts of the Taunton Corporation electricity works for the year ended Dec. 31, 1901, the total expenditure on capital account is given as £52,586. Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc., are given below:

Dr. Revenue Account.	£	s.	d.
Generation of electricity	2,380	13	9
Repairs and maintenance	150	18	7
Distribution of electricity	89	13	8
Attending and repairs of public lamps	290	5	3
Royalties—free wiring	291	13	0
Rents, rates, and taxes	131	14	5
Management expenses, etc.	836	16	1
Special charges—insurance, etc.	820	7	4
Total expenditure	4,991	12	1
Carried to net revenue account	2,680	14	1
	£7,672	6	2

Cr.	£	s.	d.
Sale of current per meter	4,068	2	5
Tramways company for current	204	13	2
Public lighting	2,242	6	9
Rental of meters and other apparatus	209	3	3
Rents receivable	5	4	0
Sundry installations and sales	842	16	7
Sale of machinery displaced by arc rectifier plant	100	0	0
	£7,672	6	2

General Balance-Sheet.

Dr. Liabilities.	£	s.	d.
Capital account—amount of redeemable debenture stock	27,066	15	9
Temporary loan	15,500	0	0
Sundry creditors	1,505	12	4
Balance at credit of net revenue account	75	15	8

Sundry debtors for current supplied	2,548	14	6
Other debtors	450	8	2
Stock redeemed and stock redemption fund	4,466	3	0
Suspense account	498	11	3
Balance at debit of motor purchase account	1,206	0	7
Cash in hand	5	9	7
	£62,625	10	10

Statement of Electricity Generated, Sold, etc.

Quantity generated in B.T. units			582,672
Quantity sold: Public lamps	137,040		
Quantity sold: By contracts	840		385,907
Quantity sold: Private consumers by meter	248,027		
Quantity used on works			98,202
Total quantity accounted for			484,109
Quantity lost in mains, transformers, etc.			98,563
Total maximum supply demanded (kilowatts)			435

Number of public lamps: arcs, 72; incandescent, 8 50-c.p., 17 32-c.p., 168 16-c.p., 32 8-c.p.

KINGSTON ELECTRICITY WORKS.

In his eighth annual report on the past year's working of the electricity undertaking, Mr. J. E. Edgcome, the borough electrical engineer, says: "I greatly regret I should again have to present to the committee an unsatisfactory balance-sheet. For three months of the period embraced by this report, owing to the contract then in force, the heavy price of coal was maintained, and as the economy effected by the chain grate stokers and condensing plant was only felt for a few months, it has not had a very appreciable effect on the coal consumption. The amount spent on fuel has been reduced by £680. 9s. 2d. (from £4,236. 6s. 8d. to £3,555. 17s. 6d.), whereas the total number of units sold has increased by 37,472 (from 308,860 to 346,332)—that is to say, the average cost per unit for fuel has been reduced from 3·291d. to 2·464d. The total works expenditure has been reduced by £551. 13s. 7d. (from £6,387. 17s. the previous year to £5,836. 3s. 5d.), whereas the total revenue has increased by £816. 5s. 9d. (from £6,562. 11s. 4d. to £7,378. 17s. 1d.). The profit on the works before payment of interest and repayment of capital has increased by £1,367. 19s. 4d. (from £174. 14s. 4d. to £1,542. 13s. 8d.). The amount for payment of interest has increased by £310. 1s. 4d. (from £1,434. 3s. 5d. to £1,744. 4s. 9d.), and the amount for repayment of capital has increased by £631. 14s. 8d. (from £1,461. 12s. 7d. to £2,093. 7s. 3d.), although as yet a portion of this capital expenditure has not earned any revenue. The result of the year's working, after payment of interest and repayment of capital, is a debit balance of £2,294. 18s. 4d., as against £2,721. 1s. 8d. during the previous year. As pointed out in previous reports, the heavy costs of repayment of principal, which have to be met before the plant has commenced to be remunerative, bears very heavily upon municipal electrical undertakings, and I am glad to say that very strong representations have now been made to the Government authorities, and it is hoped that such representation will be favourably considered at an early date, and that all provincial municipal electrical undertakings will be placed on the same footing as certain metropolitan municipal undertakings, which are allowed for two or three years to make their repayment of principal on new work out of capital. The number of consumers during the 12 months has increased from 376 to 458, an increase of 82, as compared with an increase of 65 during the preceding year. The number of 8-c.p. lamps connected has increased from 18,899 to 22,885, an increase of 3,986, as against 2,769 in the preceding year. By means of the deferred payment system of house wiring, which the committee have adopted, and have carried out in a few instances, I confidently hope that a very substantial increase in the number of consumers will be made, and I hope the committee will see their way to adopt in certain cases a system of prepayment slot meters, which I feel sure would prove very popular with a large class of inhabitants, and whilst being convenient to the consumer, would be remunerative to the Corporation, and tend to largely augment the number of lamps connected to the mains."

LEGAL INTELLIGENCE.

IS A TRAMWAY A RAILWAY?

A case in the Court of Appeal (consisting of the Master of the Rolls and Lords Justices Mathew and Cozens-Hardy) on Tuesday raised an important question under the Workmen's Compensation Act as to whether a tramway is a "railway" within the meaning of the statute. It was an appeal from the refusal of the late Judge Bagshawe to award the applicant compensation for personal injuries sustained while in the employ of the London United Tramways, Limited. Mr. J. A. Compton argued the case for the appellant, and Mr. Ruegg, K.C., for the respondent.

The **Master of the Rolls**, in giving judgment, said the workman met with the accident on a line which came to be constructed under different statutory provisions at different parts of its length. At one part it was a light railway, and at another an electric tramway; or, at all events, was not brought under the light railway regulations. The particular part where the accident happened was what was known as an electric tramway line. In his opinion, however, an electric tramway should be regarded as a "railway." The appeal, therefore, must be allowed with costs.

The Lords Justices concurred.

SPEED OF THE GLASGOW TRAMCARS.

At Glasgow last week Sheriff Fyfe heard a complaint at the instance of Thomas Simpson, coalmaster, of Pollokshields, setting forth that the Corporation of the city of Glasgow had contravened Article 6 of the regulations made by the Board of Trade, in so far as on the tramway in Albert-road on Feb. 17 and 18 last they drove and propelled six

Digitized by Google

cars (none of the said cars having been fitted with speed indicators, in terms of the regulations) at a speed exceeding the maximum of eight miles an hour.

It was stated in evidence in support of the complainer's case that the speed of the cars varied from 10½ up to 19½ miles an hour.

The **Sheriff**, in giving judgment, said this case lacked two essential elements in order to bring the facts up to the contravention charged. The one was that it should be proved as a matter of fact that the cars in question were the property of the respondents, the Corporation of Glasgow, and at the time the speeds averred were being run by the servants of the Corporation. The other point was that it must be proved as a matter of fact that the cars in question were not fitted with speed indicators. While both were technicalities, they were dealing here with a criminal complaint under the Summary Jurisdiction Act, and, unless the facts proved were sufficient to support the averments, he had no alternative but to find the charge not proven, which he did.

COMPANIES' MEETINGS AND REPORTS.

MERTHYR ELECTRIC TRACTION AND LIGHTING.

The directors in their report for the year 1901 state that the total capital expenditure to Dec. 31, 1901, amounted to £86,850. 9s. 3d. The gross receipts on the tramways from April 6 (the date upon which the lines were opened for traffic) to Dec. 31, 1901, amounted to £9,587. 3s. 4d., and the gross receipts on account of electrical supply from July 22 amounted to £2,104. 17s. 8d., making, with £80. 3s. 9d. sundry receipts, a grand total of £11,772. 4s. 9d. After deducting expenses amounting to £7,129. 6s. 9d., and £1,434. 12s. 3d. for debenture and other interest, there remains a net profit of £3,208. 5s. 9d. The directors propose that this amount should be applied as follows—viz.: to pay dividend on the cumulative preference shares to Dec. 31, 1901, £862. 10s.; to be placed to reserve and depreciation fund, £1,000; to dividend on the ordinary shares at the rate of 4s. per share, equal 5½ per cent. per annum, £1,200; to be carried forward to next account, £145. 15s. 9d. The number of private consumers now connected with the mains represent a demand equivalent to 4,313 lamps of 8 c.p. This department of the business continues to make satisfactory progress.

MEXICO ELECTRIC TRAMWAYS.

The report of the directors states that from Jan. 1, 1901, the system has been worked by this Company under the terms of the lease entered into with the Compania de Ferrocarriles del Distrito Federal de Mexico. The result of the operations for the year, after charging the interest on the debentures of the Compania de Ferrocarriles del Distrito Federal de Mexico, and the 3½ per cent. guaranteed on the share capital under the terms of the lease, shows a net profit of 9,284·34dol., which at the rate of exchange of 22½d., gives £870 to be carried to the credit of the London profit and loss account. The interest received on the debentures of the Compania de Ferrocarriles del Distrito Federal de Mexico held by this Company, and the dividend declared by that company on its share capital is then added, and, after charging the various expenses and obligations against same, a net balance is shown to the credit of profit and loss account of £16,662. After paying the preference dividend there is £4,306 available, which, together with £2,227 brought forward, makes £6,533 to be carried forward. During the year a further 200,000 6 per cent. cumulative preference shares of £1 each has been issued at par, in order to provide the necessary funds for construction purposes, leaving 112,987 shares still unissued, the proceeds of which will be devoted to construction and further extensions. The Company's service now extends over 251 km. of track, The number of passengers carried during the past 12 months was 26,709,225, being an increase of 39,165, and the receipts amounted to £209,136, an increase of £5,259, which was partly made up of increased freight returns. The operations during the year did not, from perfectly unavoidable causes, realise the anticipations of the directors. The past year has been one of the worst in the commercial history of Mexico. The outlook, however, is distinctly encouraging.

BELLISS AND MORCOM.

The report of the directors for the year ended March 31 states that the profit for the year, after making ample provision for depreciation, etc., and after payment of the preference dividend, amounts to £32,853. The directors have already distributed an interim dividend on the ordinary shares at the rate of 5 per cent. per annum. They now propose to pay a further dividend, making 12½ per cent. for the year, to place £10,000 to the general reserve fund, and to carry forward the balance, together with the amount brought forward from the preceding year. The directors have made a further issue of preference shares; these have been placed at a premium, which has been added to the reserve fund.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Falkirk.—The Town Council will shortly advertise for tenders for piping and cables.

Nuneaton.—The Urban District Council invite tenders for a water-tube boiler and pipework. Tenders by 18th inst.

Shanghai.—The last day for receiving tenders for the proposed municipal tramway and motor 'bus service is June 30.

Sophia (Bulgaria).—The General Post Office require tenders for £2,000 worth of telephone and telegraph material. Tenders by June 9.

West Ham.—The Council invite tenders for 50 double-deck electric tramcars, complete with electrical equipment. Tenders by July 8. See advertisement.

Manchester.—The Tramways Committee invite tenders for the supply of line materials, trolley wire, etc., for overhead equipment. Tenders by June 14. See advertisement.

Bristol.—The Electrical Committee invite tenders for feed and general service pumps, water-softener, and tank coke filters and pipework. Tenders by June 20. See advertisement.

Valparaiso.—The Municipality are inviting tenders for electric lighting and tramways. We understand that particulars may be obtained from the Chilian Consul. Tenders by Sept. 1.

Bury.—The Tramways Committee invite tenders for the supply and delivery of rails and fishplates, fishbolts and nuts, tiebars, points and crossings, and sole or anchor plates. Tenders by June 24.

Walsall.—The Corporation invite tenders for the supply and erection of a reversible booster and switches, to work in series with a battery on a tramway circuit. Tenders by June 27. See advertisement.

Brighton.—The Town Council invite tenders for the supply of 300 tons of steel girder tramrails. Specifications, etc., may be obtained from Mr. Thos. B. Holliday, tramways engineer, Lewes-road, Brighton. Tenders by June 9.

West Ham.—The Corporation invite tenders for the construction of about eight miles of route length of tramways. Specifications, etc., may be obtained from the offices of Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster. Tenders by June 10.

Brighton.—The Town Council invite tenders for the supply of points, crossings, tiebars, bolts, and other fittings. Specifications, etc., may be obtained on application at the office of Mr. Thos. B. Holliday, tramways engineer, Lewes-road, Brighton. Tenders by June 9.

Warrington.—The Corporation invite tenders for the following: (Section 11) tramcars, with motors and electrical equipment complete. Specification, etc., may be obtained at the offices of Messrs. Preece and Cardew, 8, Queen Anne's-gate, Westminster, S.W. Tenders by June 18.

Launceston (Tasmania).—The Corporation invite tenders for polyphase generating, transmitting, and distributing plant and apparatus, transforming apparatus, reconstruction of existing plant, and enclosed arc lamps and accessories. Tenders by Sept. 15. See advertisement.

Kirkcaldy.—The Corporation invite tenders for wiring the central station. Specification, etc., can be obtained from Mr. Wm. L. Macindoe, town clerk, or seen at (but not obtained from) the office of Messrs. Kennedy and Jenkin, 17, Victoria-street, Westminster, S.W. Tenders by 21st inst.

Manchester.—The Tramways Committee invite tenders for: (a) chilled cast-iron car wheels and axles; (b) lamp glasses for cars. Specifications may be obtained from Mr. J. M. McElroy, general manager tramways department, 55, Piccadilly, Manchester. Tenders by 1 p.m. on 14th inst.

Stretford.—The District Council invite tenders for the following in connection with its scheme for supply of electrical energy: Steam-raising plant, comprising boilers, superheaters, economisers, etc.;

Digitized by Google

generators, comprising engines, dynamos, condensers, pumps, etc.; and mains. Tenders by June 18. See advertisement.

Tonbridge (Kent).—The Urban District Council invite tenders for the fitting-up of an electric light installation in their electricity works. Specification, etc., may be obtained at the offices of Mr. Robert Hammond, M.I.C.E., consulting engineer to the Council, 64, Victoria-street, Westminster, London, S.W. Tenders by June 9.

Astrachan.—Erection of electric generating station and installation of public and private lighting, commencing with 150 arc and 6,000 incandescent lamps. Manufacturers who will undertake to finish the work within two years can obtain particulars from the Municipality. Agents will not be able to tender. Tenders by June 7-20.

Ipswich.—The Corporation invite tenders for the supply, delivery, and erection at the generating station, Constantine-road, Ipswich, of engines and dynamos, storage battery, overhead hand travelling crane, feeders, mains, and road work, permanent-way construction of tramways, and arc lamps. Tenders by July 5. See advertisement.

Little Woolton.—The Urban District Council invite tenders for (1) supply, laying, and jointing of cables and the supply and fixing of junction boxes and lamp connections: and (2) supply of lamp fittings. Specification, etc., may be obtained from the surveyor, Mr. Richard Simmons, Grange-lane, Gateacre, near Liverpool. Tenders by 20th inst.

Stockton-on-Tees.—The Corporation invite tenders for the supply, delivery, and erection of one 300-kw. steam generator, two Lancashire type boilers, one switchboard panel and instruments, surface condenser and cooling plant, pipework and valves, extension feeders, and mechanical stokers, economiser, and feed pump. Tenders by June 17. See advertisement.

Rotherham.—The Corporation invite tenders as follows: (Specification No. 12) tramway and lighting feeders, mains, and other cables, with roadwork; (13) boilers—first extension, consisting of three Lancashire boilers, with mountings, erected complete; (14) additional steam dynamo, with normal output of 320 kw., erected complete. Tenders by June 17.

Bury.—The Tramways Committee invite tenders for the work required in the construction of the permanent way in several parts of the borough—viz.: Fairfield section, Bolton-road section, Heywood-street and Knowsley-street sections. Specifications, etc., can be obtained on application at the office of Mr. Arthur W. Bradley, borough engineer and surveyor. Tenders by June 24.

York.—The North-Eastern Railway Company invite tenders for the following articles in such quantities as they may require during six months ending Dec. 31, 1902, delivered (carriage paid) at the telegraph stores at York: telegraph apparatus and telegraph wire and line stores. Particulars may be obtained on application to Mr. Graves, Telegraph Department, York. Tenders by noon on June 9.

Worthing.—The Corporation invite tenders for the erection of a circular brick chimney shaft for their electric generating station, High-street, Worthing, 140ft. high from the ground level and 7ft. 6in. inside diameter at the top (the Corporation will construct the foundations and other brickwork to the ground level). Full particulars can be obtained on application to the Borough Surveyor, Municipal Offices, Liverpool-road, Worthing. Tenders by June 16.

Rotherham.—The Corporation invite tenders for the following materials: 2 pairs of cable jacks; 1 hand cart; 1 watchman's box; 200 yards of fencing chain with spikes; 1 tar boiler; 1 portable Weston voltmeter, with case, ranging from 0 to 300 and 0 to 600 volts; set of 6 Crosby indicators complete, with accessories and case; set of stocks and dies: 300 yards of ·1 - ·05 - ·1 triple-concentric Callender's vulcanised-bitumen sheathed cable; 250 yards of ·035 concentric cable, as above; 500 yards of ·022 ditto; 500 yards of ·012 ditto; 50 service boxes; 50 fuse boxes; 10 tons of bitumen. Tenders by 14th inst.

RESULTS OF TENDERS.

Southampton.—The tender of Butler and Co. has been accepted for an 18in. shaping machine, at £142, less 2½ per cent. discount.

Ilkeston.—The Tramways Committee have accepted the tender of Moss and Sons, of Loughborough, for the construction of car-sheds at £6,950.

Eccles.—The tender of Chapman, Hollinworth, and Son to erect a wall 9in. in thickness at the generating station, at £100, has been accepted.

Worcester.—Messrs. Fownes Bros. have accepted the tender of Willans and Robinson, of Rugby, for one of their standard compound engines for mill-driving.

Colchester.—The tender of the Oak Building Company, Cambridge, at £2,242, has been accepted for the works in connection with the extension of the electricity station.

Birmingham.—Messrs. Dunlop and Co. have accepted the tender of Willans and Robinson, of Rugby, for two 250-h.p. engines for direct coupling to dynamos for electrical power purposes.

The Underground. — The Metropolitan and District Electric Traction Company, Limited, have placed the order for the storage battery for their electric traction scheme with the Electrical Power Storage Company, of 4, Great Winchester-street, London, E.C.

Manchester.—The Chamber Colliery Company, of Hollinwood, have accepted the tender of Willans and Robinson, of Rugby, for one of their standard compound engines for direct coupling to a dynamo for supplying power for electrical coal-cutters and other motors about their colliery.

Shipley.—The tender of the Westinghouse Company for the supply of 30 carrier lamps of the Bremer type has been accepted, and arrangements made with the Anchor Cable Company to send an expert to superintend the cable-laying, a two years' guarantee to be given on the completion of the work.

Hull.—The tenders of Belliss and Morcom, Birmingham, for an additional engine for the power station, at £1,774, and the tender of Siemens Bros. for additions to the switchboard, at £184, have been accepted. The clothing for the tramway drivers and conductors is to be supplied by R. S. Burn, and that of the inspectors by Clarke and Son.

Mansfield.—The tender of Crompton and Co., Limited, Salisbury House, London wall, E.C., at £2,486, has been accepted for the construction and erection of the following plant for the municipal electricity works: (Section I.) pipework, valves, and tanks—steam, exhaust, water, and other pipes, valves, tanks, footplates, and accessories.

Poplar.—The following tenders have been received for the electric wiring and fittings at the Guardians' offices: A. H. Marshall and Co., £289. 10s. (accepted); F. Cramer and Co., £407. 8s.; W. Simmonds and Co., £407. 18s.; C. H. Cathcart and Co., £585; E. Ryan and Co., £679. 13s.; Jackson Bros., £507; London Electrical Engineering Company, £998; Geipel and Lange, £756; Laurence and Co., £514; Pitford and Estall, £463. 15s.

Hammersmith.—The Council have accepted the following tenders: Pain and Son, Walworth-road, for decorating the Broadway and Shepherd's Bush-green, and for illuminating such decorations on Coronation Day and the following day, £257; J. E. Spagnoletti and Co., Goldhawk Works, Goldhawk-road, for electrically illuminating the town hall and Shepherd's Bush library, £212. The illumination of the Starch Green Pond enclosure is to be carried out by the borough electrical engineer at a cost not exceeding £35.

Fulham.—The Borough Council have received the following tenders for the supply and erection of a 600-kw. steam alternator:

The following recommendation has been made by the committee: (*a*) that the tender of Dick, Kerr, and Co. for the sum of £5,290. 4s. be accepted, subject to their undertaking to complete the contract within six months; (*b*) that in the event of Dick, Kerr, and Co.

Digitized by Google

declining the contract on the above condition, the tender of the General Electric Company, with the Willans engine, at £4,125, be accepted, subject to the completion of the contract within the period of six months. The consulting engineer in his report points out that taking £600 per lb. of steam as representing the true capital value of the steam consumption, the lowest tenders work out considerably higher than (some of them more than double the amount of the tender) those recommended for acceptance. A. Consumption full load.

Aberdeen.—The Corporation have received the following tenders for a 20-ton electrical crane: J. Carrick and Sons, Dalry Ironworks, Edinburgh £1,288 (accepted); Royce, Limited, Hulme, Manchester; S. H. Heywood, 37A, Fountain-street, Manchester; Mavor and Coulson, 47, King-street, Mile End, Glasgow; Carrick and Ritchie, Waverley Engineering Works, Edinburgh; Crompton and Co., Salisbury House, London-wall, E.C.; C. and A. Musker (1901), Limited, Liverpool; International Electrical Engineering Company, Strand, W.C.; T. Broadbent and Sons, Central Ironworks, Huddersfield; Craven Bros., Osborne-street, Manchester; Higginbottom and Mannoch, West Gorton, Manchester; J. Booth and Bros., Rodley, Leeds; J. Spencer and Co., Chamber Ironworks, Hollinwood; Wimhurst, Hollick, and Co., London; J. M. Henderson and Co., King-street Engineering Works, Aberdeen; Verenigte Maschinenfabrik Augsburg und Maschinenbaugesellschaft, Nurnberg, Germany.

Devonport.—The following tenders have been received for supply of all materials in connection with and the execution complete of the following works, for the Corporation: (Contract A) permanent way, road bed, paving, and bonding of 3 miles 1 furlong 2·08 chains of double tramway track, and all incidental and special works:

W. C. Shaddock, Plymouth	£35,127	15	1

C. L. Duke, Plymouth	43,224	6	8
Pethick Bros., Plymouth	44,952	16	8
W. Winnard, Wigan	46,146	11	0

BUSINESS NOTES.

TRACTION.

Rotherham.—A site for car-sheds has been acquired in Rawmarsh-road.

Blackburn.—It is reported that the loss on the tramways for the past year is about £6,000.

Bolton.—Complaints are being made of the slow progress in relaying the tramway in Chorley New-road.

Dudley.—The British Electric Traction Company are proposing a tramway from Ocker Hill to Great Bridge.

Lancaster.—Satisfactory progress is being made with the work of constructing the electric tramways in the town.

Shoreham.—A draft of the Bill proposed to be promoted by the tramway company will shortly be considered in committee.

An Abandoned Tube.—The City and Brixton Electric Railway Abandonment Bill has passed a Select Committee of the House of Commons.

Dundee.—The Tramways Committee have decided to set aside £500 as a beginning to meet claims for compensation in respect of accidents on the tramways.

Ilkeston.—The Tramways Committee have appointed Mr. O. A. Pilcher, of Blackburn, electrical engineer and manager of the proposed tramways at a salary of £250 per annum.

Twickenham.—The overhead equipment of the tramway from Busch Corner to Twickenham is progressing rapidly, and the opening of the line will probably take place about June 20.

Hammersmith.—At the Borough Council meeting on Wednesday the Parliamentary Committee recommended that the draft agreement with the London United Tramways Company be sealed.

Wrexham.—The Borough Council and the Wrexham and District Electric Tramways Company have now come to terms with reference to the supply of current for the tramways, and other matters.

Batley.—The statement that the construction of electric tramways here is to be indefinitely delayed is entirely devoid of foundation. The work of laying the lines will shortly be proceeded with.

Garston.—The Council have confirmed a recommendation of the Works Committee to petition against the Bill transferring the electric light and tramways undertaking to the Liverpool Corporation.

Manchester.—On Sunday the inauguration took place of the tramway to Stockport, along Stockport-road, and to Denton, by way of Hyde-road, under the electric system of the Manchester Corporation.

Chatham.—The electric cars were expected to commence running one day this week over the entire system of tramways which has been laid down by the British Thomson-Houston Company in Chatham, Brompton, and Gillingham.

Gloucester.—The light railway scheme proposed by the County Council provides for the construction of a line from Gloucester city boundary to Brockworth, a distance of between three and four miles, at an estimated cost of £40,000.

Speed of Motorcars.—At a meeting of the council of the Central and Associated Chambers of Agriculture in London on Tuesday, a resolution was adopted demanding that all motorcars should carry a distinctive number in front and rear.

Clydebank.—The Clydebank and Glasgow Corporations have now practically settled their differences on the tramway question. The Glasgow Corporation have virtually agreed to take over in its entirety the burgh's tramway provisional order.

Elland.—At their meeting on Wednesday night the District Council passed a resolution regretting that the Halifax Corporation have not taken any steps to provide a service of tramways for Elland, and asking when the line will be commenced to Elland.

Devonport.—While descending a steep hill on Tuesday an electric car left the rails and, colliding with a lurry, turned over on its side. The conductor was seriously injured, and many of the inside passengers were cut about the hands and face by broken glass.

Maidens and Dunure Light Railway.—The Ayrshire County Council have granted the application of the promoters of the above scheme for leave to construct a level crossing for a 3ft. gauge light railway in Longhill-avenue, near Burns Monument.

Wakefield.—Much disappointment is felt in the town at the delay in the tramway scheme. At a meeting of the City Tradesmen's Association on Tuesday night it was resolved to write the promoters, through their local agents, and enquire how matters stand.

Sheffield.—A public meeting convened in the Crookesmoor district of the city has passed a resolution protesting against the decision of the Tramways Committee to discontinue the Harcourt terminus, and a deputation has been appointed to wait upon the committee.

Nidd Valley Light Railway.—Under the Light Railways Act an order has been granted by the Commissioners, and confirmed by the Board of Trade, authorising the construction of a light railway in the rural district of Pateley Bridge from Pateley Bridge to Lofthouse.

Surrey and Sussex Light Railway.—Formal notice has been given that application will be made to the Light Railway Commissioners for an order authorising the construction of a system of light railways between Ockley, in Surrey, and Selham, in Sussex.

Gillingham.—The Council have determined to call upon the tramway company to carry out work of repairing and altering levels of roads and paths in various parts of the district. The Board of Trade inspection of the new lines took place on Wednesday week.

Southend-on-Sea.—Formal notice is given that application is intended to be made to the Light Railway Commissioners by the Corporation for an order authorising them to lay down light railways in the borough of Southend and the urban district of Shoeburyness.

Pontypridd.—Two petitions on behalf of the Taff Vale Railway Company and frontagers praying to be heard by counsel against the Urban District Council's Tramways Bill when the committee stage is reached, have been deposited in the Private Bill Office of the House of Lords.

Woodbridge and Bawdsey Light Railway.—Notice is given that application is intended to be made to the Light Railway Commissioners by Sir William Cuthbert Quilter, Bart., and Major Algernon Waller Cobbold for an order authorising the construction of the above railway.

Leeds.—An illuminated tramcar has been making the round of the city the last two or three nights in celebration of the successful result of the peace negotiations with the Boers. For the purposes of the rates the tramway profits for the past financial year have been taken at £47,000.

Kidderminster.—The directors of the Kidderminster Electric Tramway Company have passed the estimates for the construction of a tramway from Kidderminster to Bewdley, and the plans are now being prepared. It is intended to lay down the line in the autumn of the present year.

Newcastle.—In accordance with a suggestion of the city engineer a number of tramway poles are to be fitted with guards at the bottom, particularly those on Byker Bridge. The Tramways Committee have ordered that 25 cars be fitted with magnetic track brakes at a cost of somewhere from £40 to £50 per car.

St. Helens.—Negotiations between the Corporation and the tramway company have culminated in an agreement under which the company will have the right to use the tramcars for the carriage of goods on certain terms. The Corporation are applying for leave to borrow £23,000 for tramway purposes.

London County Council Tramways.—Good progress is being made with the work of electrifying the London County Council tramways from the Tooting terminus to Westminster. About 1½ miles in all of the down track of the permanent way has been taken up, of which less than a mile is now complete.

Eccles.—The Council have confirmed the action of the Parliamentary Special Committee with regard to the agreement made with the Salford Tramways Committee for the appointment of agents and arbitrators in acquiring land in Eccles and Patricroft for the widening of the main roadways for electrical tramway purposes.

Huddersfield.—Major Druitt, R.E., on Wednesday inspected the electrically equipped tramway from Northumberland-street to Sheepridge. It is expected that within the next 10 days the Birkby, Honley, and Almondbury sections will be ready for electric traction. The permanent way of the Honley section is already completed.

Yarmouth.—A successful trial trip of one of the new Corporation electric tramcars was made last week. The tramways—now very near completion—have been laid with great rapidity, and had it not been for the delay in supplying points, progress would have been even more marked. The work of laying the lines was commenced in October last.

Digitized by Google

Ainsdale.—A request of the Parish Council that the Birkdale District Council should receive a deputation in reference to the extension of the Southport Tramways Company's system to Ainsdale, has been complied with in so far that it has been resolved to accede to the suggestion after the tramways now in progress in the district have een completed.

Heywood.—A special meeting of the Town Council was held on Saturday to seal an agreement with regard to the purchase of the Bury, Rochdale, and Heywood tramways. The agreement related to a joint contract being entered into between Heywood, Bury, Rochdale, Littleborough, Royton, and Unsworth for the acquisition of tramways on a common date.

Private Bills.—In the House of Commons the Croydon and District Electric Tramways Bill, the North Metropolitan Tramways Bill have been read a third time. In the House of Lords the following Bills have been read a third time: Wrexham District Tramways Bill, Edgware and Hampstead Railway Bill, and Manchester Corporation Tramways Btll.

Dewsbury.—Petitions are being received by the directors of the Yorkshire (Woollen District) Electric Tramways, Limited, asking that certain places may be fixed upon at which cars shall stop to take up and put down passengers on the line of route, which, when completed, will extend from Cleckheaton, through Heckmondwike and Dewsbury, to Ravensthorpe and Thornhill.

Stockport.—A runaway car on the electric lines of the municipal tramway system on Wednesday jumped the lines at some points, and, rushing at a tangent across the road, crashed into an extensive shop front, badly wrecking it, and buckling up the front of the car. Though much damage was done nobody was injured. A similar accident happened near the same spot a few months ago.

Burnley.—The Corporation have received an intimation from the promoters of the proposed tramway from Accrington to Burnley that they have abandoned for this year their application, though they may renew it next year in the form of a Bill. The company intended to construct a tramway from Accrington to Burnley, passing through Huncoat and Hapton, and the Burnley Corporation had given their support to the scheme.

Ayr.—Colonel Yorke has made an inspection of the Burns Monument section of the electric tramways. Among other appliances, Colonel Yorke inspected a new signalling apparatus in connection with the block system over the single line which has been invented and manufactured in the Corporation workshops. He expressed himself as satisfied with it, and with everything he had seen. The line is now open for public traffic.

Colchester.—The borough electrical engineer and borough surveyor have been instructed to jointly prepare a report setting forth in particular their views and recommendations relative to (1) the merits of the several Continental tramway systems; (2) the hills in Colchester, some of which are of steep gradient; (3) the suggested widening of North Bridge; and (4) the proposal for erection and use of a refuse destructor in connection with the tramway system.

Salford.—Arising out of some recent fatal accidents on the electric tramways, a question was asked the deputy-chairman of the Tramways Committee at the meeting of the Town Council on Wednesday as to whether these were not due to the excessive rate of speed at which the cars travelled. In reply, it was stated that the speed of the tramcars was well within the Board of Trade limits, and none of the accidents had really been caused by excessive speeds.

Levenshulme.—The application of the Council to borrow £8,064 for the purpose of electrical equipment for tramways in the district has been granted. The electric cars have already commenced running. Notice has been given to the Council that the Manchester Corporation are desirous of placing a loop line in the village to enable return cars to stand and receive passengers, as Levenshulme is for certain cars a terminus, and also of erecting a temporary structure on land adjoining the road.

Doncaster.—On Monday those portions of the tramways laid between Station-road and Balby and Hexthorpe and from Station-road to the sheds in Greyfriars-road were formally inaugurated, comprising 3 miles 1 furlong and 5 chains of the nine miles the Corporation are empowered to lay. The other portions are to the racecourse and to the head of Avenue-road. The total estimated cost is £77,500. After the formal opening the cars were run to Balby and Hexthorpe, and were well patronised.

Crewe.—It was stated at a meeting of the Town Council on Wednesday that the Electricity Committee are in negotiation with a private company with a view to the provision of a scheme of electric light railways for the borough. The committee were originally desirous of promoting a light railway scheme of their own, and taking any profits which might have been derived from it. But the ratepayers, at a recent poll, declined to allow them to proceed with it as a municipal concern.

Bath.—An announcement was made at the last meeting of the Town Council to the effect that a clause in the agreement with the tramway company provides for the completion of the undertaking within three years of the date of the order, which was last December. The surveyor has already prepared plans showing the present routes, and also those abandoned or suspended. It was further stated that Sir Henry Bramwell has inspected the existing tramway area, and will commence his arbitration on the 13th inst.

Deptford.—The Works Committee having considered a letter from the chief engineer of the London County Council stating that in connection with the equipment of the tramways along New Cross-road with the electrical conduit system it would be necessary to alter the bridges conveying the road over the lines of the London, Brighton, and South Coast and South-Eastern and Chatham Railways, a reply has been sent that, provided that no alteration is made in the present level of the road, the Borough Council are prepared to acquiesce in the arrangement suggested.

Blackpool.—The Tramways Committee have decided to revert to the former 2d. stages on the promenade system. A short time ago there was an agitation for 1d. fares, and in consequence 1d. stages were substituted. The real test of their success was in Whitweek. On the first four or five days the receipts decreased to the extent of between £700 and £800. On the Friday, Saturday, and Sunday at the end of the week, although there were 13,000 more passengers carried, the returns were down £70 as compared with the same period last year.

Nottingham.—At the meeting of the City Council on Monday a member asked the chairman of the Tramways Committee whether there was any objection to the publication of a weekly return of the tramway receipts for the information of the public. The Chairman of the committee replied that he did not think any good result would accrue from the publication of these returns. If they had a good week there would be someone to propose a reduction of the fares by one-half, which they were not prepared to agree to. Still, as a matter of courtesy, he would bring the matter before the committee.

Aberdeen.—The electric cars are now running to Bridge of Don on the King-street section of the bridges route, and to Abergeldie-road on the Holburn section. The electric service on the Bayview and Queen's Cross route has also been started. The work of equipment of the Rosemount branch is being pushed on as speedily as possible, and it is expected that it will be completed in the course of a fortnight. When this is done the whole system will have been finished. One of the electric car drivers has been fined 20s., with the option of 10 days' imprisonment, for having driven a car recklessly in George-street and collided with and damaged a brake.

Stockton.—At the last meeting of the Chamber of Commerce a discussion was raised on the speed of motorcars. A resolution was passed: "That this Chamber deems it absolutely necessary for the regulations to be enforced in reference to the speed of motorcars, in the interests of the public safety, and resolves that the speed should not exceed 12 miles per hour, and on the approach of any horse or horses the man in charge of the motor should be required to decrease the speed or stop altogether on a signal being given by the person in charge of the horse; also that all motorcars and bicycles be numbered with a large and distinctive number."

Liverpool.—An inquest has been held by the city coroner into the circumstances of the death of a child, who was killed by being run over by an electric tramcar. Mr. Sanders, for the Corporation, said that the question of guards was under consideration by all the electric tramway authorities. Other authorities thought the net or shelf guard was the best, but in Liverpool they thought the plough-shaped guard was better, and they were adopting it as rapidly as possible. It was the wish of the Tramways Committee to have the most efficacious guard possible. The jury found that the death was accidental, and exonerated the driver from all blame.

Gateshead.—At a meeting of the Tramways Committee on Friday the question of the proposed change in fares was considered. Hitherto ½d. stages have been in operation in the centre of the town, while 1d. fares were charged in the outlying districts. The tramways company offered to abandon the halfpenny stages and to charge 1d. for any distance on each of the sections The committee, by a substantial majority, agreed to recommend the Town Council to accede to the company's requests, provided that necessary safeguards were adopted, so that if the new system did not prove remunerative the company would revert back to the present system of fares.

Glasgow.—The Tramway Department report a record year's operations up to and including Saturday last. The drawings amounted to £612,794, as compared with £484,872 for the previous year, while no fewer than 163,600,000 passengers were carried, being an increase of a little over 31,000,000. On Sunday the reduction of fares came into operation. The ½d. stations remain unaltered, but four consecutive ½d. stages are covered by the 1d. fare. This, of course, means that many passengers who at present pay 1½d. will in future ride the same distance for 1d. The Lower Ward District Committee of the Lanark County Council have approved the plans of the tramways proposed to be laid by the Glasgow Corporation on Kirkintilloch-road.

Halifax.—The Tramways Committee have resolved to commence a system of parcel traffic on the tramcars. Town offices for the receipt of parcels to be conveyed by the cars are to be opened, and arrangements are being made to have an agent at, or as near as possible, the end of each 1d. stage on the outward journey to receive parcels. The construction of the tramways to Sowerby Bridge has now been commenced. At present the work at King's Cross will only be continued to the top of Pye Nest Park-road, but when the Corporation Bill has been passed by Parliament, the line will be continued down the new road through Pye Nest Park. In the meantime, the making of the line from Bolton Brow Board School to Wakefield-road end will be pushed forward.

Rawtenstall.—Colonel Boughey and Mr. H. A. Steward have held an enquiry into an application for powers to construct a light railway from Holcombe Brook to Rawtenstall, by way of Ramsbottom and Edenfield. The scheme was opposed by the Lancashire and Yorkshire Railway Company on the ground of competition. After hearing some of the evidence Colonel Boughey said the Commissioners had carefully considered the arguments put before them with regard to competition, and although they were quite satisfied that the line in the district, especially the one to serve Edenfield, was very greatly desired, they still felt that, in view of the decision of the Board of Trade in the Staines and Egham case, it was useless to carry this application further.

Alexandra Park.—The trustees of Alexandra Palace are prosecuting their scheme for running an electric tramway through the grounds

Digitized by Google

up to the entrance of the building. There can be no question as to the great convenience of the intended line, but it is strongly opposed in the district on the ground that it would spoil the park. As a matter of fact, however, the tramway would not go through the park proper, but merely along the valley in the lower grounds. In the same way, great objection is taken to permitting the tramway company to erect a generating station against the palace, though this will be a valuable source of revenue, and will certainly be no more of an eyesore than many similar buildings incidental to the management of the Crystal Palace at Sydenham.

Waterlooville Light Railway.—Great progress is being made with the new light railway, which is calculated to vastly improve Portsmouth's means of communication with Waterlooville and Horndean. The line, which is being built by the Provincial Tramways Company, has already reached the top of Portsdown Hill, and it is not expected to take long to complete the remaining five miles to Horndean. In fact, under the provisional order, the company are called upon to complete by July 1. The current will be supplied by the Portsmouth Corporation from their Fratton power station. Nine cars are on order, and are to be stored at a car shed now being completed at Waterlooville. The cost of the line will be between £60,000 and £70,000, or £10,000 a mile. A penny a mile will be the ordinary fare.

Metropolitan Railway Bill.—The Court of Referees of the House of Commons yesterday week considered the application of the London County Council to be heard against the Metropolitan Railway Bill. The Bill authorises the Metropolitan Railway Company and the Harrow and Uxbridge Railway Company to execute further works and acquire additional lands for the enlargement and improvement of the Baker-street Station. The land sought to be taken for this purpose, and for the making of platforms, sidings, approaches, and other works, is situate in the parish of St. Marylebone, and it was the contention of the London County Council that the company should be placed under statutory obligation to widen Marylebone-road and Allsopp-place, and to construct the frontage of and entrance to the station according to plans to be approved by them. It was to preserve their powers under the Management and Building Acts in this respect that the County Council asked for a *locus* to appear. The court, without calling upon the promoters, disallowed the application.

Paddington.—With respect to the proposed widening of Ladbroke-grove and the construction of a tramway from Uxbridge-road to Harrow-road, the Works Committee at the last meeting of the Borough Council reported having received a letter from the London County Council communicating the total cost of the suggested street widening in Ladbroke-grove (exclusive of laying down and paving the tramway track), amounting to £58,500, the cost of the portion within Paddington amounting to £38,040. The London County Council asked the Borough Council to consent to the tramway and to contribute one-third of the cost of the street widenings. A similar letter had reference to the proposed widening of Cornwall-road, Carlton-terrace, and Walterton-road, and the construction of a tramway from Ladbroke-grove to Edgware-road, the total cost of the suggested widenings being £90,700, and the cost of the portion within Paddington amounting to £69,200. In both cases the Council decided that they were prepared to consider as to giving their consent, but were not prepared to contribute anything to the cost.

Trafford Park Light Railways.—Colonel Boughey and Mr. H. A. Steward, Light Railway Commissioners, at the end of last week held an enquiry into the application of the West Manchester Light Railway Company to extend the time limit for the compulsory purchase of lands and property, and for powers to construct a short branch connecting their present system with the Cheshire Lines, near their engine sheds, and to make various other alterations in their system in Trafford Park. By an order of 1899 they had permission to join with the Cheshire Lines at Water Meetings, but owing to the purchase of a plot of land by the British Westinghouse Company the line sanctioned in 1899 had to be abandoned. There are 2¾ miles of the West Manchester Light Railways made, and last year these showed an excellent traffic return. Colonel Boughey said the Commissioners would frame a draft order and submit it to the Board of Trade. Of the great many points raised, the best way of dealing with them would have to be considered by him and his colleague, and a copy of the order as framed by them would be sent to all the parties concerned, whose observations thereon would be invited.

Cardiff.—The electric cars are now running on Sundays. Last Sunday's takings from 17 cars amounted to £104. 17s. The number of cars now delivered by Messrs. Dick, Kerr, and Co. is 41 out of the first order of 54, but 10 of these are not yet ready for service. All the double-deckers have arrived, and one out of 14 of the single-deckers Of the latter, about half a dozen will be required for the Cathays section, and the others will be used where necessary, according to circumstances which may arise. In addition to the 54, there are now on order another 40 cars, which will complete the complement for the present. With regard to the uncompleted work on some of the sections, it is expected that Bute-street will be electrically equipped within a week, High-street to the workhouse in a fortnight, and the Cathays route in three weeks. This means that in three weeks' time, if sufficient cars are delivered, the whole of the original scheme will be in working order. The proposal of the Glamorgan County Council for the extension of the city tramway system outside the borough boundaries was considered by a joint meeting of the Parliamentary and Tramways Committee on Monday. Eventually a committee was appointed to meet the representatives of the County Council.

Wolverhampton.—Up to the present there is still no probability of an arrangement being come to between the Corporation and the British Electric Traction Company whereby tramway communication with the outlying districts may be completed. We understand that the Corporation have now made the company the following offers: (1) either that the company shall at their own expense lay down and electrically equip on the overhead system the lines which shall connect Bilston and Willenhall with the borough; or (2) that the Corporation shall be responsible for one-half of the short length on the Lorain system, and that the traction company shall be responsible for the other half on the overhead system. The latter proposal is, of course, absurd on the face of it. It really means that two entirely different systems should be worked on a length of line of considerably under a mile—an arrangement which has no advantages, but, on the contrary, has many difficulties in its way. The proposal of the traction company, on the other hand, is that the Corporation shall at their own expense construct and electrically equip the short length, the traction company giving them every facility so to do. This would enable the cars of the Corporation and the traction company to meet and exchange passengers.

Maritzburg.—By the last mail we received a copy of the *Natal Witness*, in whose columns we find a most interesting report by Mr. F. W. Jameson, borough engineer, and Mr. W. F. Skidmore Ashley, borough electrical engineer, on electric tramways for the city of Maritzburg. The scheme which these engineers propose appears to us to be extremely well thought out, and one which, on the face of the figures given, the Municipality would do well to adopt, not only as the best means of efficiently opening up the townlands, but as a thoroughly good investment. The present scheme provides for one mile of double and 4½ miles of single track on a 4ft. 8½in. gauge. The total cost of the system is estimated at £74,580, with a probable annual expenditure of £16,673. 10s. Against this the engineers estimate the receipts based on the assumption that the average number of passengers carried per car mile will be eight, and that the fare will be 3d. per car mile, at £20,592, so that there is a good margin left for profit. Up to this point the scheme seems to have met with the general approval of the city, but there is one matter mentioned in the engineers' report which is the subject of much controversy. Deciding in favour of the single-deck car as more suitable for the needs of the city than the double-deck car, the report goes on to recommend that the "sliding bow" should be adopted in place of the ordinary "trolley" in practice in Great Britain, in America, on the Continent, and in other parts of the Globe. Now, the "sliding bow," as our readers know, is a German system, and the proposal that this should be employed in a loyal British colony like Natal has come upon the local Press as a shock. With few exceptions, all the papers in the colony condemn the policy favoured by the borough officials of "having their tramways made in Germany," and it is argued in favour of the trolley system that all the best American and British engineers have adopted it, as well as other towns in South Africa, Australia, and New Zealand. The further plea is put forward that foreign articles should not be encouraged in a British colony. The point urged by Messrs. Jameson and Ashley in favour of the sliding bow may be shortly summarised as follows: less wear on the overhead wire, especially when rounding curves; more silence in action than the trolley; less complication in overhead wires at curves and turn-outs; ears and frogs of more substantial design; no soldering of overhead wires necessary; no trailing rope from back of trolley arm required; no possibility of jumping off the trolley wire, as "bow" is reversible, so that in changing direction of car the lights would not be put out; and, finally, "sparking" possibilities are greatly reduced. Thus the controversy proceeds, and if the voice of the local Press is allowed to prevail, the Maritzburg tramways will be truly British, and nothing of foreign make is likely to gain a footing in that city. The whole matter was to be discussed in open council about the middle of last month, and we wait with interest to see with what favour the "sliding bow" will be received by the City Fathers themselves.

London United Tramways.—On the 29th ult. the House of Commons Committee of which Mr. Compton Rickett is chairman, commenced the hearing of evidence in support of the London United Tramways Bill. In his opening statement Mr. Balfour Browne, K.C., described the proposals of the promoters for extending their existing system of electric tramways in the counties of London, Middlesex, and Surrey. The total length of the company's lines in operation was 16 miles, and, in addition, there were 46 miles authorised. The system was partly worked by electricity. The proposed extensions had a length of 15 miles, and included short lengths in the Hammersmith district to connect the parts of the existing system, the one running from Hammersmith-broadway to Isleworth, with authorised extensions westwards, and the other running from Shepherd's Bush to Southall; a line connecting Hammersmith with Barnes, Mortlake, and Richmond, a line from Wimbledon to Malden, and a line northwards from Wimbledon to Hammersmith along the road on the east side of Wimbledon Common. From Richmond to Kew there was in operation a horse tramway, but it had long been the view of the company, now shared by the local authority, that this should be reconstructed and equipped for electric traction. In connection with this part of the proposals, important road widenings would have to be carried out. Between Mortlake and Barnes the riverside route would be followed, and there the company undertook to construct an embankment and a wall at a cost of about £30,000 at the instance of the Barnes local authority, which would be a great public benefit, preventing the flooding that often occurred. An understanding was arrived at last year with the London County Council in respect to so much of the line as came within the area of their jurisdiction, by which the short spur line at Hammersmith should be included in the purchase powers to come into operation in 1909, and a protective clause should be inserted for the crossing of Hammersmith Bridge. These arrangements were proposed to be carried out in the present Bill. On this portion of the extensions it was proposed to expend £158,752 in road widenings and improvements. Besides this, arrangements have been made with various local authorities, payments being made for extensions of the time of purchase. From the

Digitized by Google

terminus of the authorised line at Malden, on the south of the Thames, the proposed line would be carried in a north-easterley direction, and connect with Tooting and Clapham Junction. The line connecting North and South Wimbledon would serve as a much-needed access to Wimbledon Common, and the objection of frontagers on the route would not, he thought, weigh with the committee against this public advantage. On the Wimbledon portion of the present scheme it was proposed to expend £180,056 in road widenings and improvements. The various local authorities were friendly to the proposals, and he hoped that an arrangement would be arrived at with the London County Council. The opposition of frontagers was of the usual character, and the petition of the London and South-Western Railway Company was grounded on apprehension of competition, which no doubt would arise, for the railway service was not satisfactory. With the completion of the system it would be possible to travel at a tramway fare of 5d. between points for which the third-class railway fare was 1s. 3d. Evidence having been given by the chairman of the Surrey County Council in support of the proposals, Mr. J. Clifton Robinson, engineer to the company, gave the engineering details of the different sections of the scheme, and described the connections which would be effected. He stated that at the present time construction was proceeding at the rate of 1½ miles per month, and every week £10,000 was paid in wages. The line from Isleworth to Twickenham and well on towards Hampton would, he hoped, be opened next month. His earlier estimate of traffic had been amply justified, and over the 16 miles of lines in operation 243,000 passengers had been carried in a day. The population of the districts traversed was 412,000 at the last census, and was rapidly increasing. The Chairman said the committee were agreed that they could not consider that part of No. 14 line which was proposed from the cap of Wimbledon-hill to the point where it was assumed it would connect with the line to Putney, which, though shown on the plan, was not yet authorised. It would take some time to make this announcement, but it would be open to the promoters to submit evidence and arguments in favour of carrying the line to a point on the top of the hill for passengers for the common. The continuance beyond the committee was not disposed to allow. At Monday's proceedings Sir Douglas Fox stated that the proposed tramway extensions were necessary additions to the existing system of the London United Company. The line between Richmond and Hammersmith was greatly needed. The line from Mortlake to Barnes would form an excellent means of communication between London and Richmond, and would prove valuable to Mortlake. Hammersmith Bridge was quite strong enough to admit of the passage of electric cars over it. A protective clause should be inserted in the Bill for the benefit of the County Council. Line No. 10 would be an important connection between Wimbledon and Lower Tooting in a thickly-populated working-class district. Further evidence in support of the scheme was taken on Wednesday, and the committee adjourned.

LIGHTING AND GENERAL.

Greenhill.—The new public hall is to be lighted by electricity.

Stockton.—The charge for current for motive power has been reduced.

Taunton.—The extension of the electricity works will be opened on June 23.

Nelson.—Three pupils have been selected for the electrical engineer, Mr. A. Fraser.

Bootle.—A scheme of street-lighting, estimated to cost £7,500, is in preparation.

Stafford.—Mr. Jas. H. Clothier, who has been appointed to St. Annes, has resigned.

Cromer.—Application is to be made for sanction to a loan of £25,000 for electric lighting.

Coppenhall.—The parish church is now lighted by electricity. The fittings have cost about £200.

St. Annes.—The Urban Council have elected Mr. Jas. H. Clothier to the post of electrical engineer.

Newhaven.—The Board of Trade has revoked the Newhaven electric lighting order as from May 2, 1902.

Barnstaple.—The Town Council have agreed to fit up consumers' premises on the deferred payment system.

Rotherham.—It is proposed that the salary of Mr. E. Cross, the engineer, be increased to £250 per annum.

Redruth.—The Urban District Council have postponed the date of commencing the electric lighting to Aug. 1.

Gloucester.—The Electricity Committee have decided to supply electricity at 2d. per unit on Coronation Day.

North Metropolitan Electric Power Supply Bill.—This Bill has been read a third time in the House of Commons.

Shipley.—A scheme of electric arc lighting is to be carried out in Bradford-road by utilising tramway traction pillars.

Loughborough.—An extension of 12 months has been granted for the Town Council's electricity order, which expires next August.

Crewe.—The electrical engineer's report for the past year shows a total income of £4,690, and total expenditure £3,741, a surplus of £948.

Newark.—We understand that a draft agreement is being prepared between the Urban District Council and the Derby and Notts Electric Power Company.

Mansfield.—Electricity works at Mansfield, the foundation stones of which have just been laid, are being built for the Corporation at a cost of about £60,000.

Redditch.—The Urban District Council have agreed to supply a manufacturing firm in the town with electrical energy for motor purposes at a cost of 1½d. per unit.

Removal.—The Brush Electrical Engineering Company are removing their London offices to their previous address, Victoria Works, Belvedere-road, Lambeth, S.E.

Middlesbrough.—The question of erecting arc lights, for which the mains have already been laid and a loan of £1,350 obtained, has been referred to the Watch Committee.

Wellington.—The Urban District Council invite applications for a lease of their power under their provisional electricity supply order. Full details will be found in another column.

Aberdeen.—A number of extensions of electric mains at Torry have been approved of. The Town Council are making trials with Bremer arc lamps for the lighting in Albyn-place.

Stretford.—The District Council have decided to apply for sanction to borrow money for electricity purposes, and expect to be able to supply electricity in nine months from getting authority.

Provisional Orders.—Electric Lighting Provisional Orders (No. 7) Bill has been reported for second reading in the House of Commons. No. 4 Bill has been reported for second reading in the House of Lords.

Western Telegraph Co.—The directors have declared an interim dividend, payable on June 24, of 3s. per share, or at the rate of 6 per cent. per annum, free of income tax. for the quarter ended March 31, 1902.

Wormit.—With regard to the proposed lighting of Wormit and Woodhaven, we learn that 50 of the most modern incandescent lamps will be distributed throughout the roads and streets of Wormit at a cost of £2,000.

Kingston.—At the last Town Council meeting it was proposed to appoint a committee to enquire generally into the electric lighting work, but an amendment was passed to call a special meeting to discuss the question.

Epsom.—The Council have agreed that Messrs. Laurence, Scott, and Co. should substitute two efficient engines for the two Alley and Maclellan engines erected by them, such engines to be of the standard of efficiency fixed by the contract.

Erdington.—At their last meeting the District Council postponed for three months certain street-lighting proposals because it was thought not unlikely that shortly a scheme for lighting the district with electricity might come about.

Batley.—It is proposed to appoint a clerk of works at the new electricity generating station, and the successful candidate, providing he fills the post to the satisfaction of his employers, will afterwards be appointed resident electrical engineer.

St. Pancras.—The Borough Council have instructed the Electricity and Public Lighting Committee to carry out the illumination of the town hall and the Prince of Wales-road baths in a manner befitting the occasion on Coronation Day.

Stock Exchange.—The Stock Exchange Committee have ordered Edmundson's Electricity Corporation's further issue of 10,000 6 per cent. cumulative preference shares of £5 each, fully paid, Nos. 20,001 to 30,000, to be quoted in the official list.

Eccles.—The electrical engineer has been authorised to sell incandescent lamps to any consumer of electric light. The chairman and vice-chairman are about to deal with the applications for the two vacant positions of switchboard attendants.

Callender's Cable Construction Co.—Negotiations for a fusion with Henley's Telegraph Company having taken a longer time than was originally anticipated, the directors have decided to pay another dividend of 10s., making 15s. for the year.

Camberwell.—The County of London and Brush Provincial Electric Lighting Company, Limited, are about to lay electrical conduits along the east side of Martin's-road and along both sides of Burbage-road in 2in. low-tension cast-iron pipes.

Sheffield.—The Council have received a report from Mr. R. Hammond on the site for the proposed power station at Neepsend, agreeing generally with the scheme of Mr. Fedden, and the order given to Messrs. C. A. Parsons and Co. for plant.

Dover.—Electric lighting will be very largely used on Coronation Day. The municipal buildings, the monument on the parade, the clock tower, and the Prince of Wales Pier will be outlined, and the castle will probably be decorated in a similar way.

Charing Cross and Strand Electricity Supply Co.—With regard to the recent issue of 40,000 £4½ per cent. (City undertaking) preference shares, 1902, of £5 each at par, we are informed that letters of allotment have been posted to the applicants.

Eastbourne.—The Electric Lighting Committee during the last year made a net profit of £3,262, which, added to the profit made last year up to March 31, made a total net profit of £5,078. It is expected that the price of current will be reduced from next September.

Gravesend.—The work of laying the electric lighting cables along the streets of the town is proceeding, but we understand that in consequence of differences between the Corporation's engineer and the building contractor the work at the generating station has been greatly impeded.

Broughty Ferry.—The Town Council will start on Sept. 27, 1902, to supply electricity for lighting purposes within the burgh at the rate of 6d. per unit, as measured by meters placed on consumers' premises. The pressure of supply at consumers' terminals will be 230 volts.

Coventry.—The Local Government Board has instructed Major C. E. Norton to hold an enquiry in regard to the application of the

Digitized by Google

Coventry Corporation for sanction to borrow £20,485 for the purpose of electric lighting and £2,000 for the purchase of motors for letting out on hire.

Hamilton.—The Council are about to dispose of a portion of Almada-hill ground for electric lighting works, at a cost of £1,300. The total cost of the works has been reduced to £31,494, and the agreement between the Corporation and Messrs. Edmundson, London, lessees of the burgh's provisional order, signed.

Tunbridge Wells.—At Wednesday's meeting of the Town Council a heated debate took place upon the refusal of the Watch Committee to allow the National Telephone Company to put up a free instrument at the town hall for police and fire brigade purposes. Finally, the report of the Watch Committee was carried by 17 votes to 3.

New Agency.—The Union Electric Company, Limited, have appointed Mr. James Gray, of 19, Waterloo-street, Glasgow, agent for the sale of their arc lamps for all industrial purposes. Mr. Gray is to arrange a showroom to exhibit the latest types of both open and enclosed, direct and alternating current, flame, and triplex lamps at work.

Bolton.—The motor department of the Corporation is making rapid progress. In the first year the department coupled up 148 h.p. and in the second year 200 h.p. Since the prices for current were reduced, in two months 90 h.p. has been added, thus showing that the lower rates are having a decisive effect. Many new applications for power are coming in.

Frome.—At the next monthly meeting of the Council it will be proposed that application be made for sanction to the borrowing by the Council of the sum of £16,400, for the purpose of the installation of works for the supply of electricity for power and lighting purposes within the Frome urban sanitary district, and that Mr. Medhurst be engaged as consulting engineer.

Sale of Plant.—A number of electric motors, nearly new, in most cases fitted with raw-hide and steel double reducing gear, are for sale by the Era Press, Leyton, where plant may be seen at any time by appointment. Particulars appear in another column. Some second-hand dynamos and motors are also on sale at Messrs. Claude Carter and Co.'s, 215, St. Vincent-street, Glasgow.

Kent Electric Power Co.—The authorised capital of this Company is £750,000, with borrowing power to the extent of £250,000. Their scheme includes the whole of the county of Kent, with the exception of the Isle of Thanet. The company has an agreement to acquire by arbitration the Chatham and Rochester Company's undertaking, where current will be required for tramways and power.

Islington.—The Council will be asked to-night to approve of the following estimates: decoration and illumination of the town hall, electric lighting station, and public baths during the Coronation festivities, £400; provision and laying of public and private supply mains, etc., in Green-lanes, £2,100; low-tension distributing mains in Camden-road and Hornsey-road, £114; and in Cloudesley-square, £100.

Jandus Patents.—We are given to understand that the litigation which has been conducted between the Jandus Company and the Davy Construction Company for some years past with reference to the alleged infringement of the Jandus Company's master patents has been brought to a close. The Davy Construction Company have now recognised the Jandus patents, and have taken a license on the ordinary terms.

Aldeburgh.—In order to provide Aldeburgh with the Post Office telephone service, it would be necessary to erect a circuit from Ipswich. The contractors for the East Anglian Telephone Company have applied for a license to provide a service for the district of Southwold, Halesworth, Leiston, and Saxmundham, and it is suggested that the company would probably be willing to connect Aldeburgh with their service.

Colchester.—The borough electrical engineer's last report states: output of electricity in units during April, 1902, 12,849; 1901, 7,853; 1900, 4,299; number of consumers at end of April, 266; (171); (96); total number of 8-c.p. lamps connected at end of April, 15,949; (10,626); (5,064). The price of electric current used for illuminating and decorative purposes on June 26 and 27 will be reduced to 3d. per unit.

Patents.—The Comptroller-General of Patents, in his report for 1901, says there was an increase in the receipts for patents fees, designs fees, and trade marks fees as compared with 1900. There were 26,777 applications for patents, against 23,924 in 1900. The number of inventions connected with cycles and cycle accessories is lower than for many years past, but all classes relating to electricity show a marked increase.

Southampton.—The Electricity Committee's last report states that applications for the supply of electric current to the extent of 3,000 8-c.p. lamps for purposes of illuminations for the Coronation have been received, and the borough electrical engineer having reported upon the capacity of the plant under his charge, and to his being able to supply current up to 5,000 8-c.p. lamps, the applications will be granted, subject to the usual terms.

Nottingham.—The Electricity Committee are about to raise £35,000 additional capital for a generating station in the Eastcroft and for the extension of mains. The committee are desirous of proceeding with the construction of the generating station in connection with the destructor at the Eastcroft, estimated at £15,500, and £20,000 is required towards the completion of the St. Ann's power station, which will cost £85,000.

Exeter.—The total payments to local firms for necessaries during the past year amounted to £2,942, while those to outside firms came to £1,966. The latter included £1,801 for materials which were all special manufactures out of the ordinary business line of local contractors, and mostly covered by patents. The electrical engineer has been asked to schedule the articles which are from time to time required, so that tenders might be invited.

Luton.—The resident electrical engineer's last report states that during the past month 3,275 units had been generated, that about 250 8-c.p. lamps were being wired, and that two motors of nearly 13 h.p. were to be connected very shortly. The report was considered as very satisfactory. The revision of the scale of charges has been deferred until the next meeting, when the committee hope to be prepared to submit a scheme to the Council.

Salford.—After a somewhat heated discussion with regard to the electricity enquiry, the Council have decided to positively decline to pay for counsel for any of the complainants. The Council have adopted an alternative system of charges for electricity - viz., a rental of 1s. per 8-c.p. lamp per quarter and a charge of 1½d. per unit. This alternative method of charging, it was explained, would affect only a score of long-hour consumers, such as hospitals.

Motherwell.—The report of the Lighting Committee of their first year's experience with electric light is most satisfactory. There has been an income of £3,036, while the total cost of working amounted to £1,000. For public and private purposes 189,000 units were produced at a cost of 1·44d. per unit. The charge for illuminating purposes will now be reduced from 5d. to 4d. per unit, and to 1½d. for over 500 units, and to consumers of under that quantity to 2d. per unit, for power.

Coronation.—We are informed that the directors of the Robertson Lamp Company have offered their workpeople's large dining hall for the use of the King's Dinner Committee for Hammersmith, the use of which the committee have been very pleased to avail themselves of, as the dining hall is the largest in the district. The directors have also decided to pay their workpeople two days' full wages for the two Coronation holidays, in commemoration of the Coronation of King Edward VII. and as a recognition of the efforts of the workpeople during an excessively busy and trying period.

Peace Illuminations.—As an example showing how rapidly electricity can be applied as compared with the installation of gas devices, we notice that the E.L.B. Company fixed up between 4 and 8 p.m. last Monday a number of illuminating devices in Regent-street, Bond-street, Pall-mall, etc. Most notable were an elaborate device at the United Service Club, and a very characteristic decoration at the P. and O. Offices, Northumberland-avenue. We are informed that a record was made by two men and one boy, who placed 280 8-c.p. lights, including six principal connections, in 1 hour 20 minutes during the evening, which, taking into consideration the difficulty of working in view of a large and demonstrative crowd, comes very close to the company's French and American time records for rapid illuminations on the E.L.B. system.

Londonderry.—At the meeting of the Council on June 3 the following motion was discussed and negatived by 20 to 12: "To rescind the following resolution, passed at a special meeting of the Council on April 26, 1901—viz.: 'That we adopt the report of Sir William Preece of Feb. 1, 1900, and proceed immediately with the carrying out of the scheme advised by him for the supply of electric light and power to the whole city, and that an application be made for a loan of £35,000'; and that in lieu thereof the following be adopted: 'That the Corporation, instead of undertaking themselves the supplying of the city with electric light and power, consider the question of entering into negotiations with some of the leading electric lighting companies, and of handing over to the company selected the supplying of light and power to the whole city for a limited number of years upon such terms as may be agreed."

Aberystwyth.—Representatives of the municipalities of Welshpool, Montgomery, Newtown, Llanidloes, Machynlleth, Aberystwyth, Towyn, and Aberdovey met in conference at the Queen's Hotel, Aberystwyth, on Thursday, with a view to agreeing on some course of united action with a view to securing an extension of the telephone to each of the places named. Mr. C. S. Dunniss, general manager of the Cambrian Railways, presided. A resolution was passed approving the proposed extension of the telephone system from Shrewsbury to the towns represented and Aberdovey, and recommending the respective councils and railway company to enter into the necessary agreement and guarantee with the Postmaster-General. A deputation from the districts concerned is to wait upon the Postmaster-General with a view to getting a reduction in the amount of the guarantee required—namely, £605—and of the period of seven years to three years. It was also agreed that the amount payable by each of the guaranteeing authorities be in the ratio which each guarantee bore to the total amount guaranteed for the whole extension.

St. Helens.—At the last meeting of the Town Council a statement was made as to the work of the electricity undertaking. Last year's profit was £260 net, which is a reduction on the previous year. There are two causes for the reduction. In the first place, the capital charges were high, owing to the extension of plant. The second cause was the reduced price charged for current to the tramways company. Last year the number of units sold to the company was 600,000, which brought in £5,773, while this year, although 8 8,000 units were thus sold, the amount received was only £6,094, the increase of current sold being 38 per cent. and the increase of receipts 5 per cent. The current supplied for lighting had risen from 211.000 units to 267,000, the revenue had increased by 30 per cent., and the increase of revenue for current supplied for motors was 83 per cent. The Chairman said last year the cost of production established a record for the country, and that cost had now been still further reduced. The total cost was 1·04d. per unit. The average price received was 2·12d. per unit, which was very low. The street-lighting was now much improved, and they had obtained the sanction of the Board of Trade to use overhead wires for the transmission of power to various works. This would mean a great saving. The minutes were passed.

Digitized by Google

West Hartlepool.—The Electric Lighting Committee have obtained £22 in settlement of claim for an arc lamp-post in Lynn-street recently knocked down by a wagon. A supply main for the supply of current is to be laid to St. Oswald's Church and other property. The request of the Corporation of Hartlepool for terms for the supply of current is being considered. The extension of the buildings to accommodate additional plant has been referred to the Management Sub-Committee.

Hull Telephones.—The Corporation Telephone Committee have not been able to come to an agreement with the National Telephone Company. The committee strongly urged a reduction of the rate to £7 for business premises and £6 for private houses, as against the company's offer of £8 and £7. The company, however, would not fix lower rates for an unlimited service than £8 and £7. The committee have now decided to oppose the Telephone Company's Bill in Parliament.

Epsom.—The Urban District Council have adopted the resident engineer's suggestion that, in order to meet the requirements of those who wished to adopt the electric light for illumination or decoration at the Coronation, a fixed sum of 1d. per lamp per night should be charged up to 50 16-c.p. lamps (equivalent to 5d. a unit for four hours), the consumers already wired to be permitted to take the current from the cut-out side of the meter, and so get the benefit of the reduced rate for the occasion.

Dartmouth.—The electric lighting company has undertaken to supply electricity for public lighting by Aug. 15. Provided the company cannot do this, and cannot make terms with the gas company for a continuance of gas lighting, the electric lighting company is to be allowed to substitute oil lamps for gas. The Council have decided not to engage the services of a consulting engineer in connection with the electric lighting works. Mr. Philip and the surveyor are to advise the Council in the matter.

Accrington.—A maximum price for current at 4d. per unit, and the minimum price of 1·25d. per unit, has been adopted. The engineer's last report states that the plant and mains are generally in good order. Main cables had been laid during the past month in Edgar-street and King-street to the extent of 435 yards run of street. Cable-laying was now being continued until all that sanctioned had been laid. Units delivered to mains for week ended May 19 numbered 1,326; units for corresponding period last year, 830; increase, 496, or 59 per cent.

Bridlington.—As indicated in our last issue, the Town Council have decided to retain Mr. F. H. Medhurst to carry out the works in connection with the electric lighting order, exclusive of the buildings. The central station will be at the Portland-place depôt, on the following alternative lines: (1) private and street lighting in the compulsory area only; (2) private lighting in the compulsory area and street-lighting in the whole of the borough now lighted with gas, with provision for the lamps to be lighted and extinguished from the central station.

Belfast.—From a statement of the electric light account for year ended March 31 last, we gather that a gross profit for the year of £9,054 has been made. After charging interest and redemption there is a deficiency of £346, which will be carried forward to the next year's accounts. The application of Messrs. Harland and Wolff, Limited, for supply of electric energy for light and power to their premises at Queen's-road, already noted by us, has been granted, and application will be made for sanction to the borrowing of £20,000 for the extension of the mains for the purpose of supply.

Electricity in Mines.—There was a fair representation of mining engineers from the North of England at the annual conference of the Institute of Mining Engineers in London last Thursday. The presidential address of Mr. James Dixon, a Scottish engineer, said coal-cutting by machinery was making considerable progress. Last year there were 48 such machines at work; most of them were driven by electricity, and did the work four times as fast as by the old methods. Electricity was also becoming popular for illuminating purposes, and would eventually be utilised for winding and pumping.

Nuneaton.—The Urban District Council have adopted a report of the Electric Committee recommending that the Council should instruct the electrical engineer (Mr. Gibson) to prepare the specifications and invite tenders for one new boiler with connecting pipework, cable required for extensions and street-lighting scheme. The report further stated that it was the intention of the committee to charge the Council the same amount for lighting the streets with electric light as was paid to the Nuneaton Gas Company for a period of 12 months, when the matter would be further considered, the number of arc lamps to be erected being 20 and the number of lamps displaced being 42. The committee are fully satisfied that a proper return would be forthcoming for the extensions of the cables about to be laid.

Dundee.—The accounts of the electricity department show that the expenditure during the past year was £18,398, which was £1,132 less than the estimate. The income was £18,616, against an estimate of £20,382. For the current year the expenditure is estimated at £25,667. 10s., and the income (including a balance brought forward of £217. 11s. 9d.) at £25,914. 15s. 9d., leaving an estimated surplus of £247. 5s. 9d. At a recent meeting of the Finance Committee the Town Clerk stated that he had had some correspondence with the Secretary for Scotland regarding the borrowing powers for electricity purposes. He explained that the Scotch Office wished to include the borrowing powers for the electricity department under the gas department borrowing powers, but the clerk replied that hitherto both departments had been treated separately. He added that the Scotch Office was still considering the matter.

Hammersmith.—The last report of the Electricity and Lighting Committee states that since the last Council meeting 14 additional consumers have been connected, representing a maximum of 383 8-c.p. lamps, the present number of consumers now taking current from the mains being 1,022. Three additional lamps are to be erected on the western side of St. Ann's-road. A set of rules and regulations prepared by the borough electrical engineer for the supply of electricity to premises for the purpose of the Coronation illuminations has been approved. The surveyor has reported that Messrs. Wimpey and Co. have satisfactorily completed their contract in connection with the condensing scheme at a total cost of £5,775. 7s. 8d., the amount of the contract being £5,823. 4s. 6d., and that the difference is accounted for by the deductions from the work included in the specification, thereby reducing the cost by £47. 16s. 10d.

Bristol.—The Electrical Committee contemplate an expenditure of £61,000 on extensions of the Avonbank works, in consequence of the rapid growth of the undertaking. The foundations are to be constructed this summer at a cost of about £10,000. Plans and estimates will be prepared by the staff, and will be submitted to Sir Benjamin Baker. The Electrical Committee in their report adopted at the last Council meeting also stated that the water-softening plant (which has not been enlarged since the initial installation in 1893) was now inadequate for the demands made upon it. The committee had received from the electrical engineer a scheme for the erection of additional plant capable of softening 8,000 gallons per hour, and for the provision and erection of additional feed-water filters, feed and general service pumps, which with the plant already laid down will meet all demands likely to arise from the present works, at an estimated total cost of £2,915, and were authorised to apply for sanction to the borrowing of the money.

Blackburn.—In his last report on the electricity department, Mr. Giles, electrical engineer, states that the cost of generating in the works has been reduced from 1·32d. per unit last year to 1·01d., and the total costs, including management and distribution to the consumers, from 1·78d. per unit to 1·48d. There is the equivalent of 82,109 lamps of 8-c.p. connected to the mains—an increase of 25,585 over last year. During the year applications were received for supply to additional motors, which now total 100, or an aggregate of 350 b.h.p. The number of consumers taking the supply for all purposes is 783, an increase of 113 over last year. The average price obtained per unit sold is 3·93d. for lighting purposes, 1·65d. for private power purposes, 1·5d. for tramway purposes. The total output from the works for the year is 2,002,141 Board of Trade units, an increase of about 72 per cent. over last year's production. During the year one additional generator has been put down and two boilers. The total capacity of the works is 3,720 h.p. The maximum load on the works at any one time was 1,406 kw. on Dec. 21, 1901. The total cost works out at £5,970 3s. 9d.—·71d. per unit sold.

Worthing.—The Electric Lighting Committee have decided to invite tenders for the supply and erection of a circular chimney shaft, 104ft. high from the ground level, the Corporation constructing the necessary foundations up to the ground level. In the course of a detailed report upon the expenditure incurred and liabilities outstanding in connection with the installation of the original scheme, the consulting engineers pointed out that the actual cost of the scheme amounted to £34,333. 12s. 4d., or £1,833. 12s. 4d. beyond the amount of £32,500 originally sanctioned by the Local Government Board, but that on the machinery and plant contract a saving of £1,602 had been effected, the tenders for the work having been less than the amount allowed in their estimates. The excess was stated by the engineers to have arisen through (1) the materials for the buildings being higher in price at the time the work was done than when the estimates were prepared; (2) extra cost incurred by the substitution of 40 arc lamps in place of 76 incandescent lamps, as originally arranged, £768; (3) arc lamp spares and spare cable taken over by the Corporation, £120; (4) alterations to arc lamp-posts, £41; (5) extra cost of manhole covers owing to greater number of manholes being required than estimated for, £153; (6) to the price of cables being much higher at the time the tenders were received than at the time when the estimates were prepared, to the excavations for the laying of the ducts costing more than was allowed, owing to the ducts having to be laid deeper than was anticipated, and to additional manholes being constructed; and (7) to the inclusion of the fee for their original report, and resident engineer's salary during the erection of installation, neither of which was included in their estimates, and to their fees having been increased owing to the greater cost of the installation. The engineers added that much of the discrepancy in cost between their estimates and the tenders as accepted was to be accounted for by the fact that their estimates were given some 16 or 17 months before tenders were invited, and in the interval prices had in most cases risen considerably.

Wellingborough.—Colonel Durnford has held an enquiry into the application of the Urban Council for sanction to a loan of £1,320 for the purpose of carrying out their scheme of lighting the streets by electricity. A refuse destructor has been placed on land which the Council own in the centre of the town, and it is proposed to utilise the surplus steam for providing light in the public lamps. Before the order applied for by the Council was granted, the Electrical Power Distribution Company obtained an order from the Board of Trade enabling them to supply electricity for all purposes, and the Council entered into an agreement with that company under which the Council might purchase their undertaking, and in the meantime would be allowed to transmit their energy along the company's mains to the bottom of the street lamps free of charge. That order has been transferred from the Electrical Power Distribution Company to the County of Northampton Electrical Power Distribution Company, who will carry out the provisions of the agreement. The Council at first intended to erect a generating plant, but arrangements have been made whereby the company will put down on the Council land certain buildings and a generating plant, and take the Council's surplus energy. This will save the Council a considerable sum, so that instead of the Council requiring a loan of £3,000, they only ask for £1,320 to carry out their part of the scheme. The building will cost £250, and the cost

Digitized by Google

of altering 287 street lamps £990, legal expenses and contingencies taking it to £1,320. The average cost of lighting those 287 lamps at present is £1. 3s. 0½d., or £330 a year. If £1,320 are borrowed, repayable in 20 years at 3½ per cent., the charge would be £90. 16s. per annum, thus effecting a saving of £240 a year. If the loan is repaid in 15 years there would be a saving in the cost of lighting of £218 per annum. In each public lamp there will be placed two lights of 16 c.p. each, and the maximum cost of adapting the lamps, from start to finish, is estimated at £3. 9s. 6d. each. It was also stated that at the present time rather more than a ton of refuse per hour was being burned, and in actual practice, without any special test, they were evaporating a pound of water to a pound of unscreened refuse.

Cornwall Electric Power Co.—The Cornwall Electric Power Company's Bill for the generation, distribution, and supply of electrical energy in bulk throughout the greater part of the mainland of the county has passed its third reading in the House of Lords. The area of supply comprises the whole of the mainland of the county except the northern outlying districts of Stratton and Holsworthy, the area being 1,100 square miles. Amongst the hindrances to the proper development of mineral wealth in Cornwall are the want of coal in the county and the high cost of internal transport. Owing to the economies effected by the use of electric power, especially in the case of machinery worked intermittently, and the advantage gained by "averaging" the working load over a large area with varying demands, the amount of horse-power—*i.e.*, 32,000 used for transport out of 460,000 tons forwarded to Cornish ports during the year—would be considerably reduced. Generating stations capable of an output of 24,000 h.p. will be provided. By placing the generating stations at the ports where the coal is delivered, the high cost of internal carriage is avoided, the loss by transmission of electricity through cables being trifling for the distances involved in comparison with the cost of transport of coal. It is proposed to make the capital of the Company £450,000, which, with £150,000 obtained, if necessary, on debentures, makes a total of £600,000. The average cost of the cables would be about £800 per mile, and the engineers consider that there should be 240 miles of such. It has been decided to provide two power generating stations—viz., one at Hayle, for 14,000 h.p., situated on the north of the harbour, on land belonging to Messrs. Harvey and Co., and adjoining their wharves and sidings, and the other at Par Harbour, for 10,000 h.p., on land belonging to Mr. C. E. Treffry. A 20-mile radius from the Hayle station embraces the important mining districts of Camborne, Redruth, and Helston, and the important centres of Truro, Penryn, Falmouth, Penzance, St. Just, and St. Ives. It extends north to within a mile of Newquay, and covers, in short, all the south-western half of the area of supply. The Par station embraces within a similar radius the china clay districts of St. Austell and Bodmin, with their tin and other mines, Newquay, Padstow, and Wadebridge, extends north to Tintagel, and east to within a couple of miles of Saltash, and overlaps the Hayle circle about four miles west of Truro. The engineers for the scheme are Messrs. C. A. Baker, of London, and J. Sturgeon, of Leeds.

PROVISIONAL PATENTS, 1902.

MAY 24.

11809. An improved electrical indicator. Archibald Denny and James Archibald Robertson, 121, West George-street, Glasgow.

11814. Improvements in means for preventing commutator sparking in dynamo-electric machines. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11815. Improvements in electric railway systems. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11816. Improvements in or relating to variable-speed electromotors. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11817. Improvements relating to electric railways. Henry Harris Lake. 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11818. Improvements in electric switches. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11819. Improvements relating to the insulation of the conductors or windings of electrical apparatus. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11820. Improvements in or relating to systems of electrical connections for current-measuring instruments. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11821. Improvements in electrical brush-holders. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11822. Improvements relating to the control of electromotor and other electric circuits. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11823. Improvements in and relating to regenerative apparatus for railway and similar purposes. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11824. Improvements relating to dynamo-electric machines. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11825. Improvements in electric transformers. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11826. Improvements in rheostats. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11827. Improvements in magnetic clutches. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11828. Improvements relating to the regulation of dynamo-electric machines. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11829. Improvements in starting devices for electromotors. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11830. Improvements in brush-holders for dynamo-electric machines. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11831. Improvements relating to the field magnets of dynamo-electric machines. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11832. Improvements in oil guards for the commutators of dynamo-electric machines. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11833. Improvements in electric switches. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11834. Improvements in electric condensers. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11835. Improvements in electric speed regulators. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11836. Improvements in commutator brushes for dynamo-electric machines. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11837. Improvements relating to electric railways. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11838. Improvements relating to controllers for electric motors. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11839. Improvements in or relating to controlling devices for electric arcs. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11840. Improvements in cleats or holders for electric conductors. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11841. Improvements in apparatus for measuring the potential or strength of electric currents. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11842. Improvements in electric meters. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11843. Improvements in fuses for electrical purposes. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11844. Improvements in or relating to devices for controlling electric motors. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11845. Improvements in electric plug fuses. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11846. Improvements relating to railway signal apparatus. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11847. Improvements relating to variable-speed driving mechanism. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11848. Improvements relating to variable-speed driving mechanism. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11849. Improvements in devices for controlling motors from a distance. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11850. Improvements relating to volt-ampere meters or direct-current wattmeters. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

11881. Improvements in electric fire-alarms. Louis John Abrahams, 6, Breams-buildings, Chancery-lane, London.

11889. Improvements in electric devices for igniting mines. Wilhelm Norres, 6, Lord-street, Liverpool. (Complete specification.)

11914. Improvements in electricity maximum demand indicators. Guy Carey Fricker, 46, Lincoln's-inn-fields, London.

MAY 26.

11919. Maximum demand indicator cut-out or switch. Frank Camillo Norman Bergh and Frank Farrer, 17, Albert-road, Brighton.

11922. Hillhouse's electric night gun sight corrector. Guy Hillhouse, 30, Charles-street, London.

11940. Improved "frog" for overhead conductors or lines of electric tramways or railways. The Palatine Engineering Company, Limited, and Ralph Blakiston, 15, Water-street, Liverpool. (Complete specification.)

11956. Improved brush-holder for dynamo-electric generators and motors and the like. Clifford Mitchell, Victoria Works, Ossett, Yorkshire. (Complete specification.)

11971. Improvements in and connected with electric incandescent lamps. John Otley Rhodes, 6, Lord-street, Liverpool.

11972. Improvements in electric accumulator plates. Alexander Fischer, 60, Queen Victoria-street, London.

11973. Improvements in negative plates for electric accumulators. Alexander Fischer, 60, Queen Victoria-street, London.

11994. Improvements in circuit-closing devices for the line selectors of telephones. Otto Graetzer, 18, Buckingham-street, Strand, London. (Complete specification.)

MAY 27.

12003. An improved feeder pillar for electric tramway and power distribution. Charles Beckingsale, 25, Clarence-square, Cheltenham.

12030. An improved electric autocar for conveying heavy articles in factories and the like. Charles Heuze, 18, Fulham-place, Paddington, London.

12075. An improved method of waterproofing electrical insulating or other materials. William Alfred Phillips, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

12078. Improvements in electrical transformers. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12079. Improvements relating to the laminated cores of dynamo-electric machines. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12080. Improvements relating to the field magnets of dynamo-electric machines. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12081. Improvements relating to lubricating devices for the trolley wheels of electric railway cars and the like. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12083. Improvements in or relating to electric arc lamps. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12106. Improvements in pull-down devices for the trolley poles of electric cars and the like. Joseph Ignatius Soudet and John Turri, 6, Lord-street, Liverpool.

12110. Improved means and apparatus for effecting telephonic intercommunication. John Young, 21, Finsbury-pavement, London. (Complete specification.)

12120. Improvements in electromagnetic brakes. William Thomas Pember, 4, South-street, Finsbury, London.

12121. Improvements in and relating to telegraphic apparatus. Antoine Damaskinos, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MAY 28.

12129. Improvements in electric arc lamps. Frank Michael Lewis and Henry Stafford Hatfield, 2, Prestonville-terrace, Brighton.

12156. Improvements in electric incandescence lamps. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.)

12157. An improvement in the manufacture of filaments or the like for electrical incandescence lamps. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.)

12158. Improvements in the manufacture of filaments or the like for electrical incandescence lamps. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.)

12159. Improvements in the manufacture of filaments or the like for electrical incandescence lamps. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.)

12160. Improvements in the manufacture of filaments or the like for electrical incandescence lamps. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.)

12161. Improvements in electrical incandescence lamps. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.)

12162. Improvements in the manufacture of filaments or the like for electrical incandescence lamps. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.)

12182. Improved manufacture of electrical glow lamps with osmium filaments. Oliver Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Oesterreichische Gasglühlicht und Electricitäts Gesellschaft, Austria.)

12201. Improvements in and relating to controlling devices for electric motors. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Compagnie de l'Industrie Electrique, Switzerland.)

12205. Improvements in means for securing cords to fittings; more especially intended for securing flexible electrical conductors with electric light fittings. Joseph Henry Golding, 47, Lincoln's-inn-fields, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published June 19.

1901.

6454. Grid or electrode for retaining plumbic oxides in accumulators to prevent disintegration during charging and discharging. Clark.

11254. Fittings for electric incandescent lights. Stead.

11257. Electrolytic incandescence lamps. Quain and Turnbull.

12382. Portable electrically-driven drilling apparatus. Campbell and Isherwood.

13468. Electrical interlocking apparatus for railway signalling. Westinghouse Brake Company, Limited, and Malan.

13665. Holders for Nernst lamps. Sheppard, Ram, and Nernst Electric Light, Limited.

14813. Trolleys and like current collectors for electric railways and tramways. Menlove.

14826. Apparatus for exhausting electric glow lamps. Imray. (Scharf.)

14930. Means for holding and working trolley poles on electric railway and tramway vehicles. Parsons.

15045. Electric arc lamps and means for stopping heat radiation in optical apparatus. Evans.

15195. Supporting conductors in conduit systems of electric railways. Chapman.

15239. Electrical cut-outs, and partly applicable to electrical switches. Bartlett.

15258. Means for raising, lowering, and suspending arc lamps. Irwin and Willans and Robinson, Limited.

15290. Method of electrically igniting the explosive mixture in hydro-carbon engines. Smith.

15371. Electric switches. Hodges.

15524. Electrically-driven blast-fans. Grüll.

16122. Working zinc and substances containing silicic acid in electric furnaces. Dorsemagen.

18530. Electric dynamos and motors. Marshall.

26203. Electromagnetic motors. Schneider.

1902.

1417. Electric meter. Wyatt.

2084. Joints and joint-boxes for electrical conductors. Wilkinson.

5592. Electric self-registering target. Williams and Edwards. (Date applied for under International Convention, Aug. 20, 1901.)

6481. Wireless telegraph systems. Shoemaker.

8488. Method of and means for producing synchronous motion. Justice. (Rowland Telegraphic Company.)

8717. Luminous-gas electric lamps. Fairburn-Hart. (General Electric Company.)

8784. Rail bonds or connections for electric railways. Lake. (Thomas.)

8872. Switches for electric lighting. Bach.

8969. Dynamo-electric generators. Haddan. (Peck.)

9229. Audible electric telegraphy. Oxlade and Richardson.

9504. Electric lamp sockets. Norden.

9704. Electric switches and wall plugs and bases for the same. Vandam and Marsh.

9788. Electric switches and applications of same to electrically-propelled vehicles. Brown.

NOTES.

The Deputation to Mr. Balfour.—We are informed that Mr. G. Balfour has appointed the hour of 12 noon on Wednesday, the 18th inst., for receiving the deputation from the Institution of Electrical Engineers on the subject of electrical enterprise.

Semi-Solid Petroleum Fuel.—News from the Continent states that some French naval experts have evolved a process whereby petroleum is made semi-solid, mixed with coal-dust, and pressed into briquettes It is claimed that a splendid fuel is thus produced, and among its advantages are economy and the absence of dust or ashes. One brick, it is said, generates the heat of four times its weight of anthracite coal.

Wireless Telegraphy.—It is reported that Mr. Marconi will on the 22nd of this month make his first attempt at Transatlantic work from his new station at Nova Scotia. This is well within the time promised by him for establishing a commercial system of wireless telegraphy between this country and America. The latest public body to adopt Mr. Marconi's system is the Belgian Railways Department, which has decided to employ wireless telegraphy on its steamers after a three months' trial.

Owens College, Manchester.—It is announced that the governors of the above college have decided to apply for a charter for an independent university, to be called the Victoria University of Manchester. In coming to this decision a few days ago the governors expressed the opinion that any powers and advantages possessed by the Victoria University and its graduates, including the use of the name Victoria, should be equally continued, if they desire, to the proposed universities of Leeds, Liverpool, and Manchester and their graduates.

Fire Losses and Causes.—A contemporary publishes some data as to fire losses and causes in the United States during 1900, which are particularly interesting, as showing the very small proportion of fires attributable to electricity as compared with those due to other causes. The number of fires registered in the United States as the result of the use of coal fuel in that year was 20,297, as compared with 5,861 with oil, 1,981 with gasoline, 1,605 with gas, and 1,054 with electricity. Thus, out of a total of close upon 31,000 fires which were found to be due to some specific cause, only about 1 in 30 was attributable to electrical causes, which should be a striking lesson to those alarmists who are ever ready to saddle electricity with the responsibility for fires the real cause of which cannot at the time be located.

Cable Rates in the West.—Several important reductions in the cable rates to Alaska, British Columbia, and the North-West Territories came into force with the 1st of this month under a decree of the Dominion Government of Canada. Taking the dollar at 4s. 2d., the new rates to British Columbia has been fixed at a minimum of 1s. 8d. a word and a maximum of 3s. 5d. a word, according to the locality which the message has to reach. In the same way the new tariff to the North-West Territories provides for a minimum charge of 2s. 9d. and a maximum of 3s. 5d. It is understood that this series of reductions is tentative, and that the experiment is to be of three months' duration. The lower rates will, of course, become permanent should an increase in the volume of traffic passing over the lines justify them.

Electrolytic Estimation of Copper in Iron.—Mr. H. Koch, describing the electrolytic estimation of copper in iron, says that not less than 100 grammes of the iron are dissolved in dilute sulphuric acid (400 cubic centimetres of 30deg. Bé) and the insoluble residual collected on a filter. If the substance is an iron rich in carbon, it is well to wash back the residue into the beaker and boil it with 200 cubic centimetres of fresh sulphuric acid to ensure the solution of the last traces of iron, then return it to the same filter, wash, dry, and ignite. It is then dissolved in hydrochloric acid, the solution evaporated to dryness with sulphuric acid, redissolved in 20 cubic centimetres of water and 20 cubic centimetres of nitric acid of sp. gr. 1·2, and after diluting to 120 cubic centimetres and adding a few drops of oxalic acid, it is electrolysed for 9 to 10 hours with a current density of 0·094 ampere per square centimetre.

An Electric Incline.—There is now in operation at Genoa an electric incline with a length measured on the horizontal of 3,520ft. and a difference of level of 615ft., giving a mean grade of 17 per cent. The system adopted is known as the rack and binding system, the rack being in the middle of the single track. The ties are supported on a strong masonry bed to prevent slipping. The cars, which are self-propelling, are so arranged that the platforms are horizontal when on the incline. The wheels are loose on the main axles, and each axle carries in the centre a large gear wheel, which engages with the track. The overhead trolley system is used, and each car is equipped with a direct-current motor of 30 h.p., working at 500 volts, which drives it by a set of reduction gears. The car descends the incline from the Piazza Principe by its own weight, and the motor acts as a brake by varying the resistance and regulating the descent at will.

Receiver for Wireless Telegraphy.—One of the principal difficulties in the way of successful wireless telegraphy has been in connection with the coherer, the problem being to get an instrument which would enable wireless messages to be read at long distances. Mr. Marconi claims to have now overcome this difficulty, and another inventor, Mr. T. Tomasina, of Geneva, has come into the field with a device, which he calls the "coherer telephone," having the same object in view. The arrangement consists of a coherer in connection with the diaphragm of a telephone receiver, the terminals of the coherer being connected respectively to the antennæ and to ground. The terminals also serve to connect a relay circuit. When the circuit is closed through the coherer by the Hertzian waves passing through the same from the antennæ to ground, the second circuit is closed in turn by the relay to operate the recording apparatus and energise the diaphragm magnet, thus producing a sound, and at the same time decohering the material of the coherer. It is claimed that the sound produced by the receiving instrument is of sufficient loudness to be heard distinctly without placing the instrument to the ear, and hence in use it is not necessary to remove the instrument from its support.

Electric Combustion Furnace.—An electrically-heated combustion tube for carbon determinations is the invention of Mr. Wm. M. Carr, which thus adds to the growing list of laboratory appliances controlled by electricity. In this arrangement the usual combustion tube, carrying at one end a roll of copper gauze and at the other a body of granular copper oxide held in place by perforated discs, is surrounded by a porcelain or other tube, upon which the coils of the heating circuit are wound. A suitable non-conducting jacket, such as magnesia, encloses the whole, and the material for analysis is placed in the usual platinum boat in the centre of the combustion tube. The heating circuit is divided, the ends of the tube being surrounded by two coils connected in series, and the central section by an independent coil; a switch and con-

Digitized by Google

tacts are so arranged that the current may be sent firs through the end coils to bring the copper and oxide to the necessary temperature, and then through all coils in series to provide an evenly distributed heat. During the entire operation a current of oxygen passes through the tube, and the products of combustion are led through the usual collecting train. The advantages of cleanliness, ease of control, and quick application of heat, all tending to rapidity and accuracy in the determination, are claimed for this device.

Paris Moving Platform.—As we recently announced in these columns, Mr. Casalonga, a French engineer, has made a proposal for providing Paris with a moving platform, running from the Place de la Concorde to the Place de la Bastille, under the Grand Boulevard, a total length of about six miles. Further particulars to hand show that the plan has been well thought out. Stairs would be installed every 650ft., one set for going in and another for going out of the shallow tunnel of the running platform. The platform itself would consist of three parallel parts, running with speeds of 2·4, 5, and 7 miles per hour respectively. A passenger walking on the third platform could thus attain a speed of from 9 to 10 miles, and it is even in contemplation to increase this to 12 or 14 miles an hour by introducing a quadruple platform. The cost is estimated by the promoters of the scheme at £340,000 per mile of double track, and the running expenses, calculated from experience gained with the moving platform of the Paris Exhibition, are put down at £80,000 a year. The present 'bus service between the places named above is far from satisfactory, and the traffic, owing to the crowded nature of the locality, is congested and slow. It is, therefore, thought that the proposed route is the most favourable that could be chosen in Paris for the experiment. The promoters propose to charge a uniform fare of 1d. Electricity would naturally be employed as the motive power.

Faraday's Law and its Range of Validity — From a consideration of the accurate measurements which have been made with the copper and with the silver voltameter, Mr. Emile Bose has come to the conclusion that the slight deviations from Faraday's law are only apparent. In the paper, abstracted in the current number of the *Journal* of the Chemical Society, in which this conclusion is expressed the author states that to test the accuracy of the law, a salt may not be used the cathion of which is capable of existing in two forms, for then there enters a possible disturbing factor due to the reaction $M^{\cdot\cdot} + M = 2M^{\cdot}$. The deviations found in the electrolysis of silver salts ($\frac{1}{10000}$ of the total weight of silver) are due to secondary reactions, an important one of which is attributed to oxygen occluded by the platinum electrode. Faraday's law, so far as the weight of substance deposited by a given amount of electricity is concerned, may be regarded as an absolutely exact law of nature. From the work of Otswald and Nernst, it is shown that we may rightly conclude that the current which passes through an electrolyte is entirely conducted by transport of material, and there is no evidence of "metallic conduction." The author regards Faraday's law as comparable with Dalton's law of multiple proportions as far as exactitude is concerned, and views it as an extension of Dalton's atomic laws.

Civil Engineers' Conversazione. — About 1,500 guests attended the conversazione of the Institution of Civil Engineers at Great George-street on Wednesday and Thursday last week. They were received by Mr. Chas. Hawksley (the president) and Mrs. Hawksley, supported by Sir John Wolfe-Barry, Sir Fredck. Bramwell, Sir Benjamin Baker, Sir Wm. Preece, Sir Douglas Fox, Sir Alexander Binnie, and Sir G. Molesworth. Included in the company were Lord Alverstone, Sir Ed. Carbutt, Lieut.-Colonel Crompton, R.E., Sir John Darston, and Sir David Hunter. In the course of the evening the guests were entertained with some very interesting scientific experiments. In the reading-room Mr. A. P. Trotter demonstrated some of the conditions under which electric shocks at 500 volts are harmless, practically repeating the experiments which he made at the Institution of Electrical Engineers a short time ago. Mr. W. N. Shaw performed several successful experiments in the library in cloud formation. The larger rooms were utilised for the purpose of displaying collections of engineering models and scientific apparatus. The exhibits included a series of models and pictures illustrating the development of transport by road, canal, and railway. A lighter form of entertainment was provided by the string band of the Royal Artillery, which played a selection of music in the hall. Vocal performances were also given in the lecture theatre and in the main library. The conversazione was quite as successful and entertaining as any of its predecessors.

Electrically-Operated Gold Dredge.—The vast superiority of gold dredgers operated by electric motors over the earlier forms of dredges is being put to good advantage in California in reclaiming some of the enormous wealth of gold lost by the wasteful methods of early mining. Some of our American contemporaries illustrate an electrically-operated gold dredger which is worthy the attention of mining engineers in our Colonies, where up to the present, owing in some instances, no doubt, to the absence of electrical power, comparatively little has been done in the use of electrical machinery in gold-mining operations. The chief point of activity in California to-day is on the Feather River at Aroville, where one company is working over an area of about 10,000 acres with electrically-operated gold dredges with the greatest success. The profits of operation, it is said, have frequently been £200 per dredge daily. Each dredger costs from £8,000 to £15,000 depending on its capacity. The working of the dredge is accomplished entirely by electric motors, the current for which is obtained from the long-distance transmission companies operating in the district. Transformers are usually placed upon the bank to lower the voltage of long-distance lines and flexible cables run from the bank to the top of the dredge, and from there to the motors. These motors, as a rule, have an aggregate capacity of 75 h.p. to 200 h.p. on each dredge. The photograph above referred to shows a variable-speed induction motor driving a counter-shaft, from which the main dredging buckets are operated. These buckets raise the material from the bed of the river to the shaking screens at the top of the dredge.

Compounding Generators in Parallel.—It is generally recognised that the operation of compound-wound machines in parallel is not usually accomplished satisfactorily unless the machines are of exactly the same type, for the reason that it is impossible to adjust the compounding of any one machine independently of the others. A system of compounding which is said to obviate this objection is proposed to be used by Mr. F. G. Baum, and is described in the current number of the *American Electrician*. He employs an exciter for the generators, which has a series field winding connected in the main circuit, so that the field strength of the exciter will vary directly with the load supplied by the generators. The exciter delivers current to the field windings of the generators in parallel, exactly as is done in the case

Digitized by Google

of alternating-current generators, and it is obviously possible by this arrangement to obtain any desired degree of compounding on all the generators, and also to vary the compounding of the machines individually in order to compensate for varying characteristics. The exciter is provided with a self-exciting shunt field winding, compounded by the windings in series with the main supply. A modification of this is also shown, in which the windings of the generators are connected in parallel with each other and in series with the exciter armature across the main line. In this case the generators would, of course, be self-exciting, and the exciter dynamo would serve merely as a booster to increase the field excitation of the generators upon an increase in load. By providing adjustable resistance in series with the generator windings, the degree of compounding may be adjusted for individual machines.

Manchester Section.—The second annual report of the committee of the above section of the Institution of Electrical Engineers shows that 12 ordinary meetings have been held in the past session, the average attendance being about 100. At the suggestion of the chairman, the committee appointed a sub-committee to call a meeting of representatives of the various Manchester societies to discuss the question of acquiring central premises in Manchester for meetings and library. The meeting was held in the Lord Mayor's Parlour on April 3, and a joint committee was then appointed to consider the question and formulate a definite scheme. It is hoped that some practical result will follow. If sufficient students come forward next session, it is proposed to form a students' sub-section. The first annual dinner was held at the Grand Hotel on Friday, Feb. 28, and proved a successful gathering, about 100 members and guests being present. The total roll of the section comprises 415 members of all grades, as against 354 last year. The committee consider that they may congratulate the members upon a successful session, and they hope that members will contribute, as far as possible, to the success of the coming session by hearty co-operation in offering papers and taking part in the proceedings. The following is the list of officers for this year: Past chairmen—Dr. Edw. Hopkinson and Mr. C. H. Wordingham; chairman—Mr. Hardman A. Earle; vice-chairman—Mr. Edw. W. Cowan; members—Dr. F. H. Bowman, Messrs. S. V. Clirehugh, A. A. Day, C. M. Dorman, W. P. J. Fawcus, A. S. Giles, J. S. Highfield, H. Lindley, G. F. Metzger, A. B. Mountain, Dr. C. H. Lees, and Mr. C. D. Taite; hon. secretary and treasurer—Mr. P. A. Ramage, Salford Ironworks, Manchester.

Tests of 220-Volt Lamps.—Interesting data are available from some lengthy tests of the performance of 220-volt lamps made by Mr. F. W. C. Bailey, and explained before the members of the American National Electric Light Association last month. Lamps of all makes were obtained, and from these 50 were selected at random and set aside for test purposes. It appears that with respect to candle-power, out of 14 lots of lamps tested one lot did not give a single lamp that came within a margin limiting the candle-power to 1½ candles above or below the normal rating. Only five lots showed a percentage above 50 per cent., and three lots a percentage of 80 or above. It is stated that at least 80 per cent. of all the selected lamps should have come within such a margin. With respect to economy, those coming within a margin limiting the lamp to one-half watt per candle above and below the rating, none of the lamps of two lots were within the margin; only four lots were above 50 per cent., and three lots reached 80 per cent. or higher. In the life tests 12 lamps of each lot were operated upon, being selected as closely as possible to the rated candle-power efficiency. The results are tabulated in terms of arbitrary candle-power areas, and no general discussion of the test is given. A final table shows that the average initial watts per horizontal candle-power varied in 14 lots from 3·36 to 5·30; that the average watts per horizontal candle-power during the useful life varied from 3·73 to 5·88 watts; that the average watts per horizontal candle-power during 1,500 hours varied from 4·38 to 6·08; and that the estimated period of useful life varied from 467 hours to 3,502 hours. Measurements made of mean spherical candle-power showed that the ratio of mean spherical to mean horizontal candle-power was quite uniform, averaging about 82 per cent. for "double oval" filaments.

A Unique Power Scheme.—When Lord Kelvin was in America a short time ago he visited Rochester, in the State of New York, and while there formulated a novel scheme of electrical transmission in connection with the utilisation of the water power of the Genesse River. The problem is one which has long claimed the attention of electrical engineers in the States, and Lord Kelvin is said to have evolved a solution of the question which is considered quite practical. According to the *Western Electrician*, the plan is to construct small and comparatively cheap dams on the Genesse River at various points between its source and the Alleghany Mountains of Pennsylvania and its mouth in Lake Ontario, wherever sufficient poundage can be obtained to give a supply of water for several months in the year. At these dams Lord Kelvin suggests turbines should be installed and connected to 2,000-volt direct-current generators. All the generators would be connected in series on a single copper or aluminium wire of not more than ½in. diameter. The single wire would form one continuous closed circuit, going back to the place of beginning by perhaps a shorter route. Lord Kelvin is reported as saying that by this method power could be economically and profitably transmitted 300 miles at a pressure of 80,000 volts. Motors would be connected in series in the circuit, and, where advisable, would be used to drive alternating-current generators. Many of the details of the scheme have also been thought out by Lord Kelvin, such as insulation devices, line construction, and provisions for automatically short-circuiting a generator in case of trouble. The doubt will, however, still remain as to the advantage of this series system over a three-phase parallel system. The fact that 80,000 volts is to be the pressure at some consumers' motors is a serious drawback to Lord Kelvin's proposal.

The Telegraphone in Multiplex.—A method of using the Poulsen telegraphone in such a manner as to record a number of messages on a single steel strip without interference with each other, is the subject of a patent recently granted to Mr. P. O. Pedersen, of Copenhagen. One of the advantages claimed for the improvement is that the size of the drum in the Poulsen invention, or the length of the wire or ribbon used, may be materially lessened, so that a long speech or a number of speeches or messages may be stored upon a comparatively short or small magnetic body. From a description of the arrangement in our American contemporary the *Electrical World* we gather that the essence of the invention is the use of two or more recording magnets, the connections of which are varied for each message, with a corresponding variation in the combined action of the magnets on the recording strip. To reproduce each message the connections of the magnets must be adjusted to the same combination that was used in impressing it. A couple of diagrammatical figures are given showing how two messages may be recorded on and reproduced from the same portions of two adjacent steel strips. These strips are drawn past the poles of two

Digitized by Google

magnets connected in series with the secondary of the telephone circuit. By means of four plugs the connections of the magnets in the circuit may be varied. A message spoken into the transmitter will be recorded magnetically on the steel strips, and may be reproduced on substituting a receiver for one of the coils, according to the well-known action of the telegraphone. By changing the connections of the magnets the polarity of one is reversed, and in this state of the magnets the original message cannot be reproduced, but while the magnets are thus connected, it is possible to fix on the steel strips an entirely new message, which will not in any way obliterate the first message, and which can be reproduced, while the connections remains the same and will not prevent the reproduction of the first message when the connections of the magnets are changed back to their original conditions. It is not necessary to use separate recording strips for each magnet, as the desired results can be obtained by using a single strip, it being necessary only that the magnets shall act at different parts of the strip. In using a drum carrying a spirally-wound steel wire, the magnets should be arranged to bear on two different convolutions of the spiral. Our contemporary also gives diagrams showing the extension of the method to four magnets, and the application of the same principle of varying combinations of magnets to the simultaneous transmission of several messages along the same wire.

Electrical Logislation in India.—For the first time in nearly 20 years an effort is being made to introduce a complete legislative system for granting licenses and for regulating the supply and use of electrical energy in the Empire of India. It is a remarkable fact that the only general Act relating to electricity now in the Indian statute-book is that dated 1887, and which merely gives power to the Governor-General in Council to formulate rules for the protection of person and property and for the prevention of injury to telegraph lines. During the past few years the matter of fresh legislation has been dealt with tentatively, but this is the first time that a comprehensive scheme in the form of a Bill has been prepared. From our contemporary, *Indian Engineering*, we learn that the Bill is entitled "The Indian Electricity Bill," and is based upon the Electric Lighting Acts and rules in force in this country. The scope of action extends to the whole of British Baluchistan, the Santhal Parganas, and the Pargana of Spiti. The ostensible intention of the present measure is to secure continuity of principle and uniformity, leading eventually to standardisation of machinery and methods, but perhaps the greatest advantage in favour of the Bill is that it will give assurance to investors and encourage them to use their capital in promoting electrical enterprise in India. We complain in this country of the evils of over-legislation in regard to the industry, but it is far better so than that there should be no legislation at all, which is practically the position in India to-day. In the old Act of 1887 no provision was made for the issue of licenses to companies, or for control by the Government of monopolies. When, therefore, in 1891, the Indian Electricity Supply Company applied to establish works at Calcutta, the Bengal Legislative Council were obliged to make a provision to enable the local government to extend its powers to any municipality in the province. The formation of the electric tramway company of Madras raised a similar difficulty as regards the breaking-up of the streets; so also did the Calcutta Electric Supply Corporation in 1896 with reference to the extension of the license from 21 to 42 years. The proposed Bill in the first instance relates to the supply of electrical energy to the public or for the purposes of traction—*i.e.*, to those undertakings which it is expedient to control by license. The next part deals with restrictions to be imposed on the use of electrical energy not supplied under the first part of the Bill, the object being to reserve to the Government power of control over unlicensed undertakings. The fourth section of the measure provides for the making of rules, the reference of disputes to arbitration, the requisite penal sanctions, and the repeal of the old Act of 1897. There is also appended a schedule setting forth certain provisions which are to be considered as incorporated with every license granted under the first part of the measure, with some exceptions.

Royal Institution.—According to arrangement, the Prince of Wales, as vice-patron of the institution, and the Princess of Wales were present last Friday night at the Royal Institution to hear Sir Benjamin Baker deliver his lecture on "The Nile Dams and Reservoir." Their Royal Highnesses were received shortly before nine o'clock by the president of the institution (the Duke of Northumberland), Sir James Crichton Browne, Sir Wm. Crookes, and Lord Rayleigh, and before proceeding to the theatre spent a short time in the library, where arrangements had been made for a few interesting experiments in electrical science. A sensitive flame taking the place of the ear in a telephone circuit and responding to every sound passing over the wires was shown by Lord Rayleigh, while Sir Wm. Crookes displayed some of the phenomena of the electric discharge in high vacua. Prof. Dewar repeated some of his experiments in the condensation of rarefied gases by extreme cold, and showed the almost instantaneous production of a very high vacuum in a tube through which the electric current was passing by the application of liquid air to the exterior. He also exhibited air in the solid state. Perhaps the most strikingly beautiful experiment was the production of a fountain of liquid air, rising to a height of about 6ft. and illuminated from above. The jet broke into spray, and the falling drops produced the most perfect condensation effects, in part evaporating and producing the phenomena of cloud formation at high altitudes, and in part falling back upon the table, and giving the effect of the rolling masses of cloud in an Alpine valley. Finally, the spray was allowed to fall into water, where it produced miniature icebergs and the general aspect of a Polar sea. At the lecture the Prince of Wales occupied the chair, with the Princess seated on his right hand. Sir Benjamin Baker, in a few words, expressed the pleasure it gave the managers of the Royal Institution to see their Royal Highnesses present at one of their Friday evening lectures, and their gratification at the Prince of Wales's acceptance of the post of vice-patron. Sir Benjamin then proceeded with his lecture, in the course of which he mentioned that the Nile reservoir at Aswân would contain over 1,000 millions tons of water. By far the most important of the works constructed to enable the water stored up to be utilised to the greatest advantage was the barrage across the Nile at Asyût, about 250 miles above Cairo, which was begun by Sir John Aird and Co. in the winter of 1898 and completed this spring. The total length of the structure was 2,750ft., or rather more than half a mile, and it included 111 arched openings of 16ft. 4in. span, capable of being closed by steel sluice gates 16ft. in height. The object of the work was to improve the present perennial irrigation of lands in Middle Egypt, and to bring an additional area of about 300,000 acres under such irrigation. After the lecture, which was illustrated in many instances by photographic lantern slides, the Prince and Princess of Wales held a reception of some of the more distinguished members of the audience and the officers of the institution.

Lamp Efficiency. — The National Electric Light Association of America held their twenty fifth convention at Cincinnati on the 20th of last month, and the *Electrical World* for the 24th ult. publishes as a supplement a very full account of the proceedings, together with a number of abstracts of papers read on this occasion. One of the most interesting subjects discussed was as to what efficiency lamp should be used, and how may this efficiency be determined, and no less than five papers were presented dealing with the subject. In the first of these, Mr. Doherty considered that the efficiency of the incandescent lamp, assuming that 16-c.p. lamps are used, should be placed at that point where the cost to the central station for the supply of current just balances the cost of lamp renewals, and that when this point has been determined for a 16-c.p. lamp, then lamps of other ratings should have an efficiency that would bring the cost of lamp renewals to the same point per kilowatt-hour consumed. In other words, when lamp renewals for lamps of a given efficiency cost more than it would cost the central station to supply additional current to yield the same amount of light from a lamp of lower efficiency, this lower efficiency lamp should be adopted. Mr. Doane, in the course of another paper, gave a table comparing the economy of using lamps of several efficiencies. If, for example, the ultimate life of a four-watt lamp is represented by 375, that of a 3·5-watt lamp is 210, and that of a 3·1-watt lamp is 130. That is to say, it is as economical to use a 3·1-watt lamp for 130 hours as it is to use a four-watt lamp for 375 hours. The next paper was by Mr. L. G. Van Ness, who considered that the life of 16-c.p. lamps on perfect regulation is 420 hours for 3·1-watt lamps, 750 hours for 3·5-watt lamps, and 1,500 for four-watt lamps, and that lamps should be changed periodically by the company On this basis the most desirable efficiency will be determined by five factors—viz., the average regulation of the circuit, the generating costs that are strictly proportional to the output, investment per kilowatt capacity of the station, the average consumption per lamp per year, and the charge per kilowatt-hour to the consumer. In the fourth paper Mr. F. W. Willcox discussed the question under a number of heads, his general conclusions being as follows: The best available economy in central-station service for the 16-c.p. lamp is 3·1 per candle. The 3·1-watt lamp can be used to advantage even when the voltage is kept 4 per cent. high, with fluctuations going still higher. No central station, therefore, which supplies current by meter should use lamps of lower economy than 3·1 watts. The best economy in smaller candle-power units is that which keeps the cost of renewals per kilowatt-hour about the same as the 16 c.p. costs. This basis gives a 3·6 watt per candle economy, or, better, for 8-c.p. and 10-c.p. lamps. An economy of four watts per candle-power is desirable for 4-c.p. and 5-c p. units, this being reduced to five watts per candle-power for 3-c.p. and 2-c.p. lamps, owing to the extreme tenuity of filament used in the same. The fifth paper was by Mr. C. D. Marsh, who considers that from a strictly engineering standpoint it would seem a simple matter for the members of the association to arrive at a proper conclusion if a table were given them, fixed factors being entered and blanks left for the variables, which each manager could insert for himself. Business policy, however, should be ever kept in mind in considering the technical branch of central-station operation.

Theory of the Electrolytic Extraction of Copper.—In the issue of the *Journal* of the Chemical Society for June will be found an excellent abstract of a paper by J. Egli containing an historical account of the methods which have been proposed for the electrolytic extraction of copper from its ores, and the disadvantages which are the causes of the non-success of these are pointed out. In connection with the Marchese process, the electrolytic extraction of copper sulphides by various solvents has been investigated, and in connection with the Höpfner process the electrolysis of cupric chloride solutions has been studied. An artificial cuprous sulphide containing some cupric sulphide was electrolytically extracted with sulphuric acid of sp. gr. 1·225 (acid of maximum conductivity). On electrolysis, the ore being made the anode, a slime is deposited on it, which soon stops the current. This slime contains free sulphur, but it is shown from the analysis of the slime progressively deposited that the solution of the copper takes place in the two phases: (*a*) $Cu_2S + SO_4'' = CuSO_4 + CuS$, and (*b*) $CuS + SO_4'' = CuSO_4 + S$. Using current densities up to 30 amperes per square decimetre the sulphur could not be oxidised. Rise of temperature favours the passage of the current. The same cuprous sulphide was electrolytically extracted with 4·5 N sodium hydroxide, the sulphide in this case being the cathode. The sulphur passes into solution, leaving metallic copper in the residual slime. Since the slime in this case has not a high resistance, the potential remains nearly constant throughout the electrolysis. The current yield is at first good, but falls off, and it has further been observed that the current yield decreases as the current density rises. The cathode slime can then be easily dissolved electrolytically in sulphuric acid, and as it contains little sulphur the previous disturbing factor is removed. The electrolysis of cupric chloride was carried out with a solution of this substance, using a platinum cathode and a carbon anode in a porous cell. When the solution is stirred, it is found that rapid stirring diminishes the yield for a given current, but the copper deposited is purer because the cuprous chloride formed by the dissolving of separated copper by the cupric chloride is washed away from the deposit. In a series of experiments, the solution circulated through the electrolytic cell and passed into another vessel containing a copper plate, and the rate at which the copper dissolved was measured. To obtain constant results, the liquid must always circulate at the same rate. Addition of hydrochloric acid diminishes the current yield, but leads to a pure copper, because the cuprous chloride formed is retained in solution. When the concentration of acid is very great, the current yield begins to increase slightly. Sodium chloride added to the solution also diminishes the current yield, but not to anything like the same extent as hydrochloric acid; the deposited copper is very pure. The current yield diminishes as the concentration of cupric chloride increases, and the copper deposited becomes more impure, for more cuprous chloride is formed, and it may even happen that cuprous chloride alone is deposited. It is not advisable, however to diminish the concentration too much, for then the copper is deposited in a very spongy form. At a temperature of about 12deg., the deposited copper is spongy; a coherent deposit is obtained at about 25deg., but as the temperature rises above this, the current yield diminishes and the deposit is not so pure. Increase of current density slightly increases the current yield, because the solubility of the copper in the electrolyte is almost independent of this density. At very high current densities, however, the current yield falls on account of the separation of hydrogen at the cathode. A deposit containing up to 99·98 per cent. of copper can be obtained from a solution containing 0·1 gramme-molecule of cupric chloride, 0·1 gramme-molecule of hydrochloric acid, and 0·4 gramme-molecule of sodium chloride per litre.

THE THEORY OF EQUALISING CONNECTIONS ON CONTINUOUS-CURRENT ARMATURES.

The following is an abstract of a lengthy article on the above subject by Prof. E. Arnold, of Karlsruhe, in the *Elektrotechnische Zeitschrift* for March 13 and 20, 1902 :

If we assume that a machine is perfectly symmetrical, magnetically and electrically, we can connect those points of the winding together which maintain the same potential relatively to one another at all points of the revolution. Under these conditions the equipotential connections would carry no current, and would consequently be valueless As soon, however, as a want of symmetry occurs—*i.e.*, as soon as E.M.F.'s of different amount are induced in the different branches of the armature—the resulting equalising currents will pass along the equipotential connections instead of passing through the brushes. In this way the load on the brushes will be reduced, and one cause of sparking will be avoided.

To ensure the correct arrangement of the equipotential connections, every circuit formed by two of these connections and the intermediate armature coils should contain equal numbers of symmetrically-situated coils connected in opposition so that their E.M.F.'s may cancel out. This condition is obviously complied with if the number of commutator segments, k, is divisible by the number of segments having the same potential.

We will first consider how the connections should be carried out with the different windings.

1. *Gramme Ring Windings and Lap Windings.*

Equipotential connections were first employed by Mordey, in the Brush Company's Victoria machines, in order to reduce the number of sets of brushes with multipolar parallel-coupled armatures to two, independently of the number of poles. In all parallel-coupled armatures the number of tapping points on the winding, or the number of commutator plates of equal potential, is equal to the number of pairs of poles, p, and the distance between two such points is equal to twice the pole pitch, or equal to the distance between two brushes of similar sign. If we call the number of commutator segments (or of tapping points on the winding) lying between the two ends of an equipotential connection, the potential step $= y_p$, then

$$y_p = \frac{k}{p};$$

p segments may be connected together, and $\frac{k}{p}$ must be a whole number.

When dealing with a multiple-parallel winding $a = m\,p$, where m is a whole number and m neighbouring segments, have practically the same potential. $\frac{k}{m\,p}$ must now be a whole number. The winding becomes multiply closed, and the potential step is, as before, $y_p = \frac{k}{p}$. In this case it is also permissible to connect neighbouring segments directly. This should, however, only be done at a few points, so that the currents in the short-circuited coils may be independent of one another. These connections will then act as equipotential connections.

2. *Series-Parallel Windings.*

In the case of the author's type of series-parallel armatures equipotential commutator segments also exist, and the determination of the potential step for these is next considered by the aid of a simplified diagram of connections devised by the writer. A distinction must be drawn between symmetrical and unsymmetrical series-parallel windings.

(*a*) *Symmetrical Windings.*—A series-parallel winding is symmetrical when $\frac{k}{a}$ is a whole number. This condition may be restated rather differently :

$$y_k = \frac{k \pm a}{p},$$

where y_k is the average span of an armature coil (front and back connections). Multiplying both sides by $\frac{p}{a}$, we get $y_k \frac{p}{a} = \frac{k}{a} \pm 1$. To make the winding symmetrical, $\frac{k}{a}$ must be a whole number; therefore, $y_k \frac{p}{a}$ must also be a whole number. But in order to make $y_k \frac{p}{a}$ a whole number, $\frac{p}{a}$ must be a whole number, so that an ordinary closed wave winding is symmetrical only when $\frac{p}{a}$ is a whole number.

(*b*) *Unsymmetrical Windings.*—When k is not divisible by a, it indicates that the a segments are not at exactly the same potential, because they are rather displaced in the field. These inequalities are, however, generally small, so that a segments can still be connected together. With unsymmetrical windings $\frac{p}{a}$ is not a whole number, so that the potential steps can no longer be equal, as they must be whole numbers.

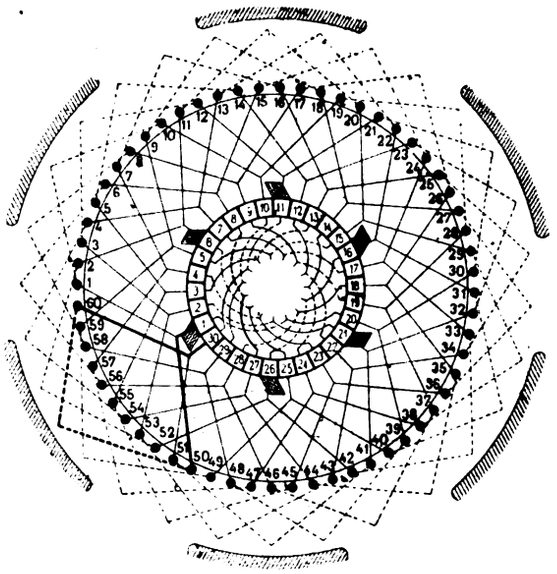

FIG. 1.

The writer suggests two methods of avoiding this want of symmetry :

1. Make $p \times y_k$ divisible by a, so that $\frac{k}{a} = \frac{p \times y_k}{a}$ is a whole number. This results in a number of separately closed circuits in parallel, the number of such circuits being equal to the common divisor of y_k and a.

2. Insert a number of sections of a lap winding sufficient to make k divisible by a. In this case $y_k = \frac{k \pm a - z}{p}$, and $\frac{p \times y_k \mp a + z}{a}$ must be a whole number. As an example, Fig. 1 shows the connections for the case when $p = 3$, $a = 2$, $z = 1$, $y_k = 9$, $k = 30$.

The rules given naturally hold good for rotary converters, and also for machines fitted with Dolivo Dobrovolsky's voltage sub-dividers. Points connected to the same collector ring must be equipotential points—*i.e.*, each collector ring must be connected to a system of a equipotential connections conforming to the conditions given.

3. *Current Strength and Loss of Power with Equipotential Connections.*

(*A*) *Parallel-Wound Armatures* (*Gramme Ring and Lap Windings*).—We will first consider a four-pole armature with an ordinary lap winding (Fig. 2), and will assume that it is set eccentrically in the field. Unequal E.M.F.'s will then be induced in the four branches, but their algebraic sum will be zero, as the winding is symmetrical and the power entering must be equal to that leaving the armature. The average value of these four E.M.F.'s will be equal to the E.M.F. which would be induced in each branch if the armature were situated centrally in the field.

Digitized by Google

By subtracting this average value from each of the four actual values we get four E.M.F.'s as remainders, of which two are additive in each half of the armature, whilst two E.M.F.'s, each equal to the average E.M.F., cancel out. Suppose, first, that the different E.M.F.'s are equally distributed over the windings, and tend in the directions, B D A, B C A, which corresponds to the case of greater E.M.F.'s being induced in the lower than in the upper branches. These different E.M.F.'s (e) give rise to currents which, in the absence of equalising connections, must pass through the positive brushes and the external connectors, and are, therefore, liable to cause sparking. If the brushes are raised and the points A and B connected by means of a wire of negligible resistance, an equalising current will flow in the wire of such amount that the drop in each armature branch will equal e. Since the armature rotates numerous cross-connections like A B must be fitted to enable the equalising current to flow continually. At the same time, if the resistance of the cross-connections is taken as zero, current will only flow in that connection (A B) which is under the brush, because, as can be seen from Fig. 2, the currents from neighbouring sections mutually cancel out as far as the other cross-connections are concerned. The losses due to the equalising currents are a maximum in this case, and $= \frac{4e^2}{R}$, where R is the resistance of one armature branch. The equalising current in one-half of the armature is $\frac{e}{R}$. If the resistance of the cross-connections is increased, the potential difference between A and B will no longer be zero, and therefore currents occur in all the cross-connections, though the total loss in the armature winding is reduced. If the brushes are now put on again, an equalising current will flow through them and their outside connector due to the difference of potential between A and B. It follows, therefore, that the greater the resistance of the equalising connections the less will the internal armature copper losses be, but at the same time the less perfect will the equalising be.

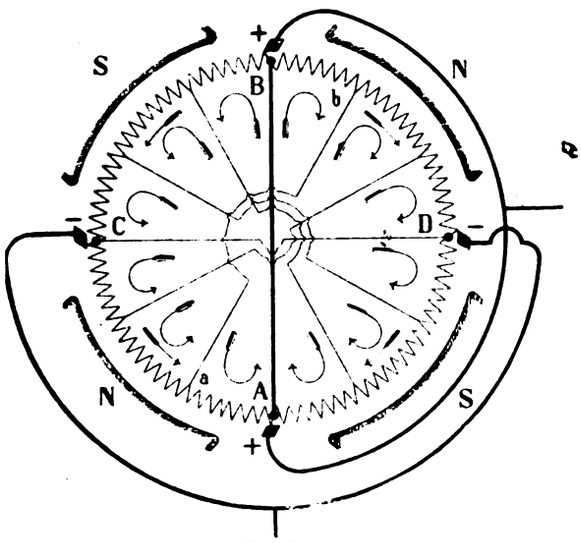

FIG. 2.

Up to the present we have neglected the effect of the armature reaction upon the field. This is incorrect. The reaction is such that the weaker poles become strengthened and *vice versâ*. The effect may become very considerable, and on this account lap windings are more or less self-regulating in respect to equal current distribution in the different branches. This self-regulation is improved by the equipotential connections. The calculation of the loss due to the equalising currents would be very involved; it depends not only on the differences in E.M.F., the reaction of the currents, the resistance of the windings and the equipotential connections, but also on the contact resistances of the different brushes.

According to recent tests carried out at the Technical High School, Karlsruhe, this contact resistance is made up of a part inversely proportional to the current density and a part which remains constant—*i.e.*, the voltage difference between a brush and the commutator is made up of a constant part of about one volt and a part proportional to the current. Since the equalising current flows in the direction of the main current at one brush, and in the opposite direction at the other, those parts of the voltage difference which are proportional to the current cancel out, so that only the constant part of the contact resistance can affect the question of equalising currents. As this latter part is very small, the equalising current will depend principally on the E.M.F.'s, the reaction, and the resistances of the windings. It is also clear that the resistances of the equipotential connections must not be made greater than the constant part of the brush contact resistance, if satisfactory equalising is to be obtained.

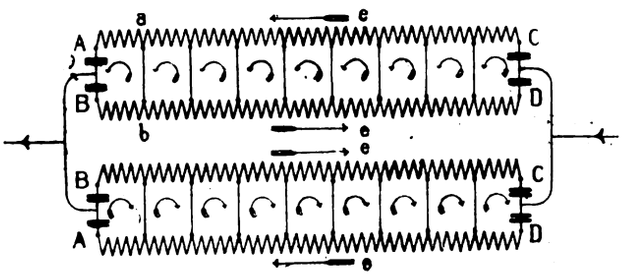

FIG. 3.

The effects of equipotential connections on lap windings are then as follows: (1) The equalising currents due to want of symmetry in the field, which previously passed through the brushes and their external connections, now pass principally through the equipotential connections. (2) The equipotential connections offer several paths of low resistance to the equalising currents, and these currents and their reaction on the field are therefore increased, and the magnetic pull on the armature is reduced. (3) As the equalising currents tend to equalise the fields, the voltage differences in the armature become less, and also the currents do not attain such large values as those due to the original voltage differences. On this account the loss in the armature is only slightly increased by the equipotential connections. (4) The connections exert an equalising effect on the commutating currents under the different brushes of like sign.

We will next consider the case in which the E.M.F.'s are no longer equally distributed over the armature branches, but have a sinusoidal distribution, which is more in accordance with the actual conditions. The arrangement in Fig. 2 may be converted into that of Fig. 3, which is more convenient in considering the directions of the equalising currents. The sign = in Fig. 3 represents the brushes. Branches A C and D B are cross-connected as well as branches B C and A D. The directions of the differences of E.M.F. are shown in Fig. 3. Neglecting the resistances of the equalising connections and of the brush contacts, the current distribution in the connections and in the armature winding will be sinusoidal. In this case the conditions are more favourable than in the first case, both as to loss and as to voltage differences between brushes of similar sign. When the machine has six or more poles the conditions become more complicated, but the general working is much the same as in the four-pole machine, so that the above statements hold good generally. In order to study the action in a multipolar machine, it is best to draw a diagram

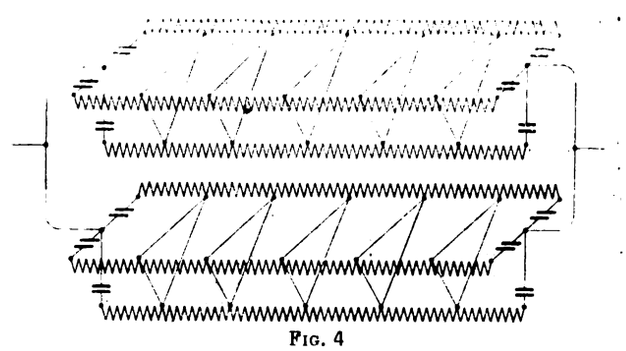

FIG. 4

Digitized by Google

as in Fig. 4, which represents a six-pole lap winding. Such a diagram, considered as a picture in space, enables the flow of the equalising currents to be readily followed.

It is worth enquiring whether it be permissible, instead of fitting every segment with an equalising connection, only to fit every third, fourth, or fifth segment with one. This question may be answered by a consideration of Fig. 2. At the moment when no connection between A and B exists under the brushes and the next one is *a b*, a voltage difference is developed between A and B, tending to produce a current through the brushes and the outside connector. This can, however, never be large, as the sum of the differences of the E.M.F.'s in the portions *a* A and *b* B is small even when only every fifth section is fitted with an equalising connection. In this case the voltage difference existing between A and B is only that due to five coils lying in the neutral zone.

(*B*) *Wave-Wound Series-Parallel Armatures.* — It is a characteristic of wave windings that they progress continuously round the armature, so that each armature path contains coils under all the poles. On this account it is hardly possible for a want of symmetry in the field to set up internal currents. On the other hand, greater differences of potential may be expected and are found to occur between neighbouring commutator segments. When the winding is symmetrical, equalising currents in the cross-connections can only occur due to want of symmetry in the fields, and are difficult to calculate. They will, however, all flow in such directions as to tend to equalise the fields, and on this account cross-connections are of service in reducing the voltage differences between neighbouring segments and in better balancing of the armature in the field. When the winding is unsymmetrical the voltage differences become greater, and may lead to small sparks between neighbouring segments all round the commutator circumference at every *a*-th segment unless equalising connections are fitted. If the contact resistances of certain brushes is too large, the current will divide unequally amongst the different brushes of like sign, and the cross-connections will act as a convenient inductionless path for the equalising currents so set up.

These connections, therefore, have the following effects: (1) the voltage differences between neighbouring segments will be equalised and more evenly divided up; (2) the unequal field strengths will be equalised, and the armature consequently better balanced in the field; (3) in case of unequal contact resistances occurring at brushes of like sign, part of the consequent equalising current can pass along the inductionless equipotential connections; (4) a more satisfactory passage of the short-circuit current is ensured.

The writer next proceeds to consider the effect of equalising connections on one or two types of unsymmetrical wave windings.

(*C*) *Application of Equipotential Connections.*—Experience has shown that it is very difficult, and in any case uncertain, to build multipolar machines so as to be magneti cally and electrically absolutely symmetrical. The same type of machine may work well in one case, and may spark and heat excessively in another. Laminated poles are decidedly conducive to magnetic symmetry. Wave windings are far less sensitive to magnetic want of symmetry than Gramme and lap windings, and yet it has been repeatedly noticed, especially with unsymmetrical multipolar wave windings, that they are inclined to spark and make good running impossible. The application of equipotential connections may, therefore, be decidedly recommended both for lap and wave windings. The Elektricitäts Aktien-Gesellschaft vorm. Lahmeyer und Co. makes use of equipotential connections on all the larger machines, especially on the flywheel type of dynamo, with excellent results.

It is not necessary to fit all segments with such a connection. Three, four, five, six, or more segments may be omitted without impairing the advantages of the equalising connections. These connections can be carried out inside the commutator, behind the commutator, on the back or front end of the armature, or on the armature circumference. In the latter case the binding bands may be employed as the equipotential connections. Equipotential connections for wave windings have been patented in Germany (No. 126,872) and other countries.

FORMERS AND FORMER-WINDING.

BY F. W. DAVIES.

(*Continued from page 805.*)

VI. Merits and Demerits of the Various Windings and Formers.

The various formers and former-windings having been described, it is now possible to make a comparison of them, with a view to discovering their relative advantages and disadvantages. As there is but one method of former-winding for field magnets, and practically but one design of former suitable for use with it, there is no need to discuss this winding. The same remark applies also to the former-winding of ring armatures. Thus, the comparison resolves itself into a comparison of the various *drum* windings and formers. It will be convenient to consider first the windings, and afterwards the construction of the formers used for those windings.

The question as to the relative merits of the three types of former-winding, the evolute, bastard, and barrel, presents itself from two points of view: firstly, from the point of view of economy of space; secondly, from the point of view of efficient ventilation.

In asking the question: What type of winding is most economical with regard to the space required at the ends? it should be remembered that the answer to the question depends to some extent upon the type of field magnet used—whether it is of the bipolar or multipolar type. Consider, first, the case of an armature for a bipolar magnet. Which winding will require the minimum of space? Manifestly, not the barrel winding; for the end winding, being carried out in a line with the active winding—that is, the conductors on the face of the armature core—projects to a comparatively great distance. The fact of the ends of the evolute winding being carried down the ends of the armature core renders this winding the more economical in this respect. In fact, it may be regarded as a barrel winding, the ends of which, instead of being carried out straight, have been bent down towards the shaft. The bastard winding requires less room than the barrel winding, but rather more than the evolute winding. For a two-pole machine the evolute winding is, undoubtedly, the most compact.

When a four-pole field magnet is used, the case is somewhat different. Owing to the angular distance between the pole centres being one-half of what it would be in a two-pole field, the arc embraced by each coil is proportionately less, consequently the end windings are not so bulky. With a barrel winding only about half the length is required for the ends that would be required in the case of a two-pole winding. In the evolute winding this economy is not fully realised, for the corresponding reduction of end-winding space with this winding would be by a reduction of the *radial depth* of the end windings. But a reduction of the radial depth of the end windings of an evolute-wound armature would obviously be of little advantage as far as the first cost and over-all dimensions of a machine are concerned. With a four-pole winding, owing to the end connectors being shorter than with a two-pole winding, they are not packed together so closely. In consequence of this it is possible to make them thicker than when a two-pole winding is used. A corresponding reduction in their width can then be made, but care must, of course, be taken that the cross-sectional area of each connector is sufficiently great. By this means the room required for the evolute end windings, also, may be reduced when a four-pole winding is used; though this reduction is only a slight one, as the space between the right-handed and left-handed groups of spirals at each end must necessarily remain the same. To summarise: the barrel, bastard, and evolute windings are practically on a par as regards the end space required for a four-pole winding, there being very little to choose between them. Whatever advantage there may be in this respect

Digitized by Google

accrues to the latter type of winding. For the armature windings of machines having more than four poles, the barrel winding, undoubtedly, occupies the least space.

The question of ventilation is a simpler one to decide. Obviously, in ordinary cases—no matter what the number of magnet poles may be—there is but little difference in the amount of cooling surface presented by the three windings. The advantage, if any, lies with the barrel type of winding. Next to this comes the bastard winding; and, although this does not *seem* to present a large superficial area at the ends, yet, owing to the interstices among the different coils at the ends, it presents a larger cooling surface than it appears to do. Sometimes the barrel end plates are dispensed with on a bar-wound armature with barrel winding. When this is done, the ventilation is excellent, for both the inside and the outside of the end windings can radiate heat freely.

It is now possible, in the light of what has been said, to decide when each particular type of winding should be used. Each winding has its distinctive sphere of application, and it is of importance that it shall be clearly understood what this is. The evolute winding, when used on a two-pole machine, has been shown to require rather less room at the ends than the bastard winding, and considerably less than the barrel winding. This means, of course, that the length of the whole machine will be less than if a bastard or barrel winding were used, which is obviously a great advantage. Therefore, the evolute winding should be used, wherever practicable, for the armatures of two-pole machines, notwithstanding the fact that the cooling surface presented by such a winding may be slightly less.

The bastard winding is unsuitable for armatures in which a large gauge of wire is used, owing to the difficulty there is in interlacing the coils with one another on the core in such a case. As regards compactness, it is inferior to the evolute winding for two-pole machines, and inferior to the barrel winding for machines having six or more poles. Its true sphere of application is for very small armatures, and for these it is generally preferable to either the evolute or the barrel winding. The chief feature in its favour is the simplicity of the coils, the winding of which is a matter requiring very little skill. With this winding it is almost impossible for any fault to occur through inexperience or carelessness on the part of the winder of the coils. On a small armature, wound with a large number of turns of fine wire, the bastard winding is the cheapest to employ.

The barrel type of winding should be used for all multipolar machines, wherever practicable, for it is safer than an evolute winding, both electrically and mechanically; and for machines having six or more poles is decidedly more compact.

With regard to the type of former to be used for the armature winding, there is not much to be said. Formers have been classified as the block and the frame types of formers. It may, perhaps, appear to be a matter of indifference which type is used for any given winding; but it will be found in most cases that there is some slight advantage attending the use of one or other of these types. As previously pointed out, each coil has usually to be made in two operations when the block type of former is used. For this reason, it would appear advisable always to use a frame former; and, indeed, this would be so, were it practicable. When a coil consists of a large number of turns of fine wire, it is an expensive method to wind it on a frame former, as with an increase in the number of turns there is an increased difficulty in keeping the wires in their places at the bends at the ends of the coils. These bends occur on the jigs in the case of a frame former for evolute winding, and on the edges of the frame in the case of the frame former for barrel winding. Therefore, for small armatures, and all those having a large number of turns in each coil, the block type of former is preferable. When there are but a few turns of thick wire per coil, a frame former should be used.

(To be continued.)

American Pacific Cable.—The House of Representatives on June 11 rejected the Bill enabling the Government to construct the proposed trans-Pacific cable.

THE SCHMIDT SYSTEM OF SUPERHEATING STEAM.

The advantage of having the steam used for driving engines superheated before it reaches the high-pressure cylinder, is recognised by all engineers who have looked into the theory of the steam-engine and know the large losses which result from condensation in the cylinders. The other advantages in using superheated steam need hardly be gone into here, but the disadvantages are also numerous unless the details of the superheater and of the lubrication of the engine are well thought out. In this last respect the Schmidt system has the great advantage of being the outcome of years of experience, and we may add that commercial success of the system has been proved again and again on a large scale on the Continent. This is so in spite of the fact that with this system the superheating is carried much higher than with the ordinary types, in which the superheat is obtained from tubes placed in behind the boiler. In fact, with an ordinary system as usually employed, most of the superheat is lost by the time the steam enters the cylinder.

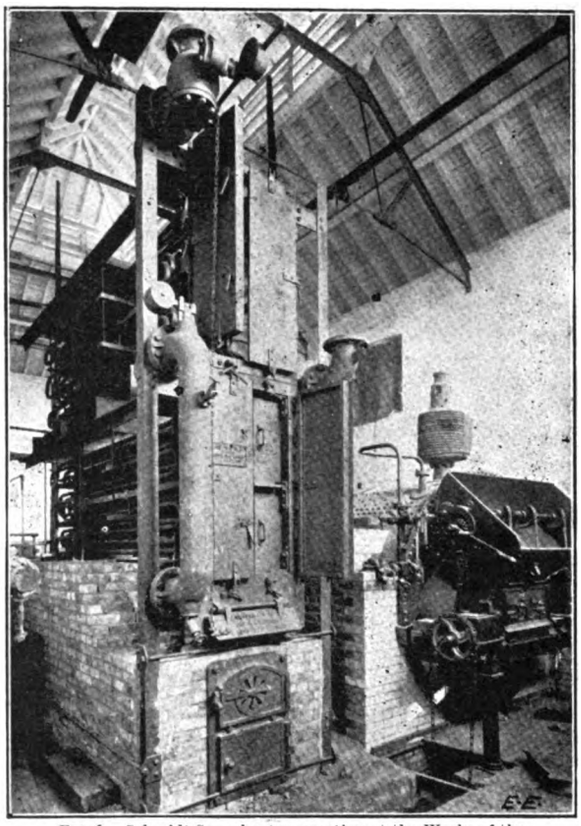

FIG. 1.—Schmidt Superheater, erecting at the Works of the British Xylonite Company.

Messrs. Easton and Co., of Erith, have taken up the license for this Schmidt system in the United Kingdom, and have already secured a number of important orders for equipments. On Tuesday last we were invited, with others, to inspect one of these superheaters at work at Erith, and to see the component parts of a large number of others in course of construction. The steam dynamo which is used to supply a large number of electric motors throughout the works is supplied with superheated steam on the Schmidt system, with wonderful results as regards both steam and coal consumption. Prof. J. A. Ewing, F.R.S., of Cambridge, has carried out a series of trials on this engine, and his report on the same is given at the end of this article, so that we need hardly describe it in detail.

In Fig. 1 is shown a superheater in course of erection at the works of the British Xylonite Company at Manningtree, Essex. It will be seen that this superheater is independently fired, which enables the degree of superheat to be conveniently regulated. In connection with this the firm are supplying two engines, each of 300 i.h.p., which will run at 140 revolutions per minute and drive three-phase alternators. The steam pressure is to be 140lb. per square inch, and with a steam temperature of 660deg. F.

Digitized by Google

the firm have guaranteed a steam consumption of 10lb. per indicated horse-power hour. The engines in this case are of the horizontal, tandem, compound condensing type, with the reheater arranged below the floor level. In this instance also the superheated steam, on its way to the high-pressure cylinder, passes round the reheater and heats up the exhaust steam from the high-pressure cylinder on its way to the low-pressure cylinder. Fig. 2 gives a cross-section of a superheater of the type used for independent firing for land purposes. The firm have supplied in all, or have orders for, plant equivalent to 45,000 h.p., and amongst these orders is a large one for the Trafford Park Power Company. The firm has already granted sub-licenses to construct engines on the Schmidt system with reheating feeders to the following firms—*i.e.*: Messrs. Bow, McLachlan, and Co., Limited, Paisley, N.B.; Messrs. James Carmichael and Co., Limited, Dundee, N.B.; Messrs. Browett, Lindley, and Co., Limited, Patricroft, Manchester; Messrs. Fairbairn, Lawson, Combe, Barbour, Limited, Belfast, Ireland; and Messrs. J. and E. Hall, Limited, Dartford, Kent. Applications are also under consideration

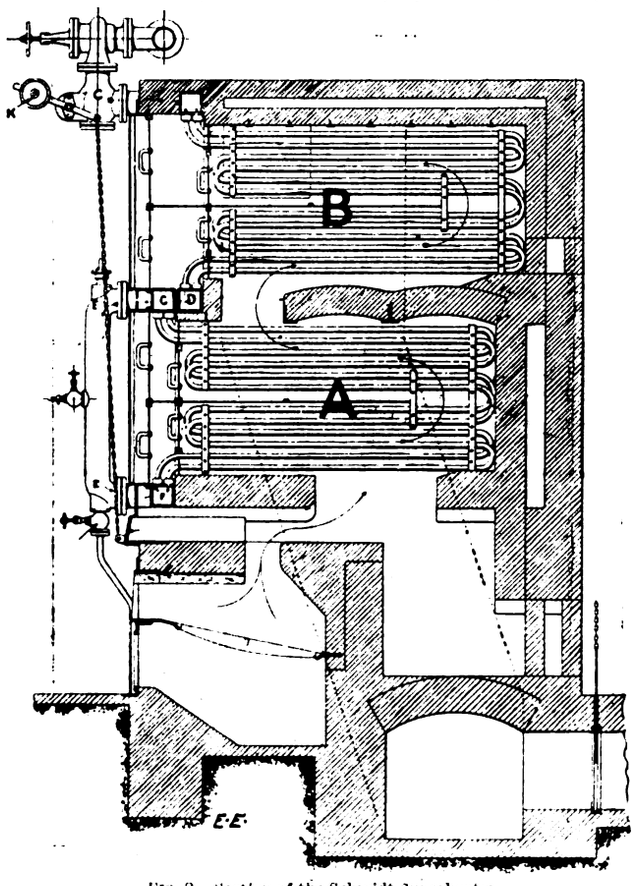

FIG. 2.—Section of the Schmidt Superheater.

from a number of first-class firms. The license of Messrs. Easton and Co. only extends to stationary engines, but on Tuesday last we were shown drawings of the application of the system to both marine and locomotive engines. The engine working at Erith was being lubricated by graphite forced in just beyond the stop valve. The supply was regulated by means of a piston working in a cylinder, which was capable of containing a fortnight's supply. The piston was slowly forced down by means of a ratchet and worm and wheel gear, worked by means of a belt from the shaft of the dynamo. The graphite was in the form of a paste, being mixed up with a mineral oil. We understand that for the horizontal types of engines the firm are using high-class mineral oils to lubricate the high-pressure cylinder.

The following is the full text of Prof. J. A. Ewing's report, which is dated March 14, 1902, and addressed to Messrs. Easton and Co.:

"On Feb. 28 I carried out a series of trials of the high-speed engine at your Erith works, to determine the steam consumption under various loads, when the engine is supplied with highly superheated steam. The engine works with triple expansion, and is of the vertical inverted double-action type, with enclosed crankshaft and forced lubrication. It runs at fully 400 revolutions per minute. It is coupled direct to a dynamo on the same bed-plate, which supplies continuous current at about 220 volts. There are three cranks set at 120deg. apart, with two cylinders in tandem over each crank. The steam expands first in one of the upper cylinders; then is divided between the two upper cylinders; and finally passes through an intermediate receiver to the three lower cylinders, which act jointly in the third stage of the expansion. In the

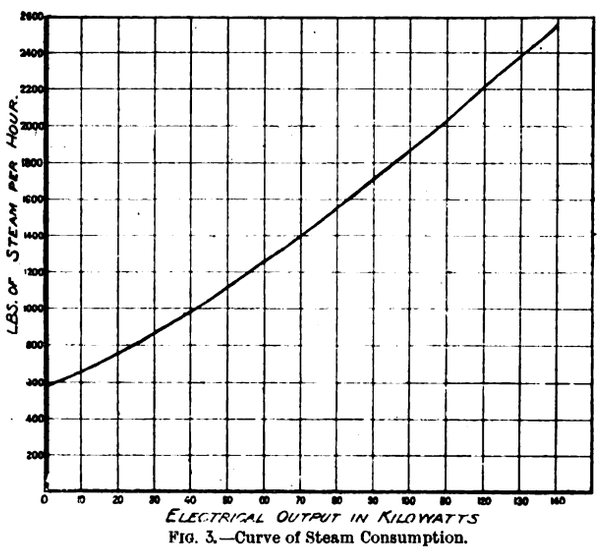

FIG. 3.—Curve of Steam Consumption.

high-pressure cylinder, and each of the two intermediate cylinders, the diameter is 12in.; in the three low-pressure cylinders it is 16in.; the stroke is 8in. The intermediate receiver is furnished with Schmidt's patent reheating arrangement, whereby a portion of the superheat is taken from the steam before it enters the engine, and is applied to dry or superheat the steam which comes from the intermediate cylinders. The distribution of steam is by piston valves in three lines, corresponding to the three lines of cylinders, with a supplementary expansion valve to control the cut off in the

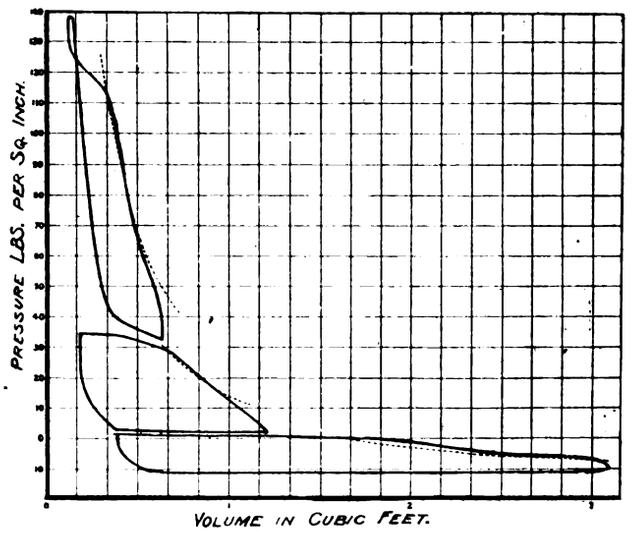

FIG. 4.—"Rankinised" Indicator Diagrams taken on the Erith Engine working with Superheated Steam.

high-pressure cylinder. This valve, which is of the piston type, is automatically regulated by a powerful shaft governor operating on its eccentric. The governor is prompt and effective in its action, and allows the load to be suddenly thrown off or on without more than a small temporary disturbance of the speed. The regularity with which the engine runs is all that can be desired. The governor is provided with a hand-wheel, which allows the speed to be adjusted at will. An oil-pump in the casing which encloses the crank draws oil from the bottom of the casing and delivers it, under a pressure of about 15lb. per square inch, through a system of

pipes to the cross-heads, and to the bearings of the connecting rods and crankshaft. Cylinder oil is delivered to the steam by a ratchet pump. I noted that the volume of oil so delivered during five hours of continuous running was barely 20 cubic inches. The engine works in ordinary use with a jet condenser, but to facilitate the measurement of steam consumption a surface condenser was temporarily used during these trials. The air-pump is independently driven by an electric motor, which absorbs about 4½ kw. The steam is superheated by a Schmidt superheater in the boiler flue. On the occasion of these trials the temperature close to the engine ranged from 350deg. C. to 380deg. C. (662deg. F. to 716deg. F.). The pressure, tested by a standard gauge at the same place, was 130lb. per square inch. The saturation temperature corresponding to this pressure is 356deg. F., hence the greatest superheat was 360deg. F. Of this superheat about 115deg. or 120deg. was given up to the low-pressure steam in the receiver, so that by the time the live steam reached the high-pressure cylinder its temperature was no more than 600deg. F. During the trials the engine ran continuously for about 14 hours, and measurements of the steam consumption were made at a series of five different loads, ranging from the full load of 140 kw. to 10 kw. The superheat was maintained nearly constant down to half load, but it fell off somewhat when the load was very much reduced, and in the trial at 10 kw. the temperature was only 295deg. C. (563deg. F.). The air-pump discharge was measured by delivery into a pair of 30-gallon measuring tanks. The electrical output was measured continuously by an integrating wattmeter, readings of which were taken at the instant when each tank became full. The readings of the wattmeter were checked throughout by keeping a systematic log of the volts and amperes on standard instruments which were calibrated in my laboratory here. The contents of the two measuring tanks were also determined by weighing in this laboratory, when the average weight of contents was found to be 298·6lb. Indicator diagrams were taken by 12 Crosby indicators. The indicated power has been determined for the full power trial, but all the trials give a direct comparison of the electrical output and the consumption of steam. To measure accurately the indicated power of a high speed engine is always a matter of some difficulty, and I attach much more importance to the measurements of electrical power. The results of the trials are given in the above table.

"The quantity of steam used per hour is shown graphically in Fig. 3 for the various trials in relation to the electrical output in kilowatts. It will be noticed that the observed quantities fall well on a smooth curve. From the curve the following table has been prepared to show the number of pounds of steam used per electrical unit generated at various grades of output:

Kilowatts	Pounds of steam used per electrical unit.
140	18·3
120	18·5
100	18·7
80	19·4
60	20·8
40	24·5
20	38·0

"The trials show that this engine, using highly superheated steam, maintains a very high standard of efficiency in regard to steam consumption throughout a large range of power from full power downwards. Good as these results are, they would doubtless have been better if the boiler had permitted the supply of steam of higher pressure. The boiler imposed a limit of 130lb., and the engine, with its triple-expansion action, would no doubt show to better advantage if the pressure were 40lb. or 50lb. higher.

"Fig. 4 shows a representative set of indicator diagrams taken during the full power trial, "Rankinised," or drawn to a uniform scale of pressure and volume. The dotted lines on this figure show the volume which would be occupied by the quantity of steam apparently present in the cylinder had this been saturated. The quantity in question is reckoned by taking in each cylinder the sum of the steam used per stroke, and the cushion steam or steam shut up in the clearance space. The "saturation" lines so drawn are nearly coincident throughout with the actual expansion curves, and show no considerable amount of superheating at any stage.

"Probably, however, they overstate the quantity of steam present (and, therefore, understate the amount of superheat), for some steam passes the valve without entering the cylinder, and this is borne out by the temperatures, which show more superheat at the intermediate pressure outlets than is apparent in the figures. What the superheat is at that stage in the expansion is rather to be judged from the following figures:

Pressure at exhaust from intermediate cylinder.	Corresponding temperature of saturation.	Actual temperature observed at intermediate cylinder outlets.
17½lb.	220deg. F.	286deg. F.

"By the action of the reheater, this steam is further superheated to 397deg. F. before admission to the low-pressure cylinder, and is thereby prevented from becoming wet at any stage in its expansion. A steam consumption of only 18·3lb. per electrical unit is a remarkably good result in view of the small size of the engine and of the fact that it was working with steam of a pressure too low to take full advantage of triple expansion, or to develop economically the engine's full power. The trials exhibit in a striking way the economy of high superheating.

"(Signed) "J. A. EWING."

SOME NOTES ON ELECTRIC HAULAGE FOR MINES.

Electricity as a motive power has now been applied to practically all industrial purposes, and owing chiefly to the great flexibility, safety, and economy of electrical apparatus, it has been found that it can replace with advantage almost every other known method of power distribution. Among the most successful applications of electrical power has been its application to surface and underground haulage in mines, both by means of locomotives and in conjunction with the rope systems.

Concentration of Plant.—Not the least of the factors which have contributed to the great success of electric haulage is the readiness with which electricity may be applied to all other mining operations requiring power, such as pumping, hoisting, lighting, coal cutting, boring,

Digitized by Google

rock drilling, ore crushing, stamping, washing, and sifting, and, in fact, all other duties apart from haulage requiring mechanical power. But perhaps the most important point in favour of electric power for this work is that it admits of the concentration of the power plant necessary for the operation of the various machines (even when these are scattered over a large area) under one roof and under the control of one staff, and also that it permits of the use of engines of large power and high efficiency in conjunction with the electrical generating plant. Thus the energy required is obtained with a minimum loss in generation, and as electric motors are most efficient machines, even through a wide range of load, the transmission losses will also be a minimum if the cables are made large enough. The cables for transmitting the power to any part of the workings can be designed to work with a loss ranging from 2 per cent. upwards of the total power transmitted, the only limiting factor being the capital invested in the necessary copper. An economical value for this loss is about 10 per cent., lost in the cable when transmitting the maximum load; this, under average working conditions, will result in a loss throughout the period of working of between 5 and 7½ per cent. These are advantages which are not obtainable in any other system, and the increase in general efficiency obtained by such concentration of power will be readily appreciated by those who have had experience with the various small engines generally found scattered about large mines, the cost of maintenance and general inefficiency of these small engines being almost entirely neglected by reason of the fact that it is never considered necessary to make any tests on them, and they are deemed to be good enough so long as they will do the work required, irrespective of the cost in steam at which they do it. The economy in fuel and water thus obtained by electric transmission is a most important consideration in dry or barren districts, such as some of the Australian diggings, where these commodities are scarce and valuable.

System of Supply.—The selection of the site for the central power-house usually determines the system of electrical distribution to be employed. If the distance from the central station to the furthest point where considerable power is required does not exceed three miles, it would be difficult to improve on the 500-volt continuous-current system, except when the distance is quite short and the pressure drop unimportant, in which case a lower voltage, such as 220, may be used, as this pressure is admirable for the electric lighting, which is always required about the works, and the danger of shock to employés and the trouble and expense of maintaining the insulation is considerably reduced by its employment. When the distance exceeds three miles, however, a high-tension two or three phase current should generally be employed, which may be reduced to any convenient pressure by static transformers at the working. As three-phase motors are equal in every respect to two-phase, and as this system requires less copper in the line for equal power transmission than the latter (assuming the same potential difference between the lines), the three-phase system, with voltages varying from 2,000 to 20,000 (depending on the length of the line) is usually employed for this class of work.

Frequency.—A very important point in connection with the choice of an alternating-current power system is that the frequency should be low, say from 25 to 50 per second. As far as lighting is concerned, no advantage is gained by increasing the periodicity beyond this latter figure, and the reduced cost of transformers for higher frequencies is more than counterbalanced in *power* plants by increased trouble in connection with the rest of the apparatus. Where it is necessary to run the generators in parallel, and to operate synchronous motors or rotary converters, it is usually best to adopt about 25 as the frequency. Apart from the above consideration, it is easier to obtain satisfactory constants for induction motors at low frequencies than at high, and where a slow-speed motor is required, some difficulty may be experienced in winding its stator for a sufficient number of poles unless a low periodicity be adopted. Taking all considerations into account, probably a frequency of about 40 periods is the most satisfactory to adopt for general power and lighting work.

Systems of Haulage.—With regard to the system of electric haulage to be employed, there is clearly no single system which can be put forward as the best for all cases, and the local and working conditions alone can determine which system or systems should be used. Where the grades are excessive and the loads heavy, it is evident that locomotives should not be employed, and, on the other hand, endless rope haulage would be found awkward and most wasteful where the tracks are long and intricate.

Rope Haulage.—Of the two kinds of rope haulage—the endless and the intermittent or reversing—the former is the most inefficient, as with it the rope is continually running over a number of not very frictionless pulleys, whether a load is being hauled or not, thereby wasting a very large percentage of the power employed. When the system is used, however, and the power supply is by direct current, the best motor to use is a *shunt-wound* motor. This, if supplied with a constant voltage, will maintain the speed of the rope constant within 5 per cent. without any attention or regulation. On the other hand, for winding engines which hoist the load either vertically up a shaft or haul it up an incline, stopping when the load has got to the top, the *series-wound* motor is undoubtedly the best; but where the load is applied to the motor through a friction clutch, the motor being allowed to run when the load is thrown off, a shunt motor should be used, as the series motor would race excessively on light load. The latter arrangement has frequently been used in the past, and in some cases even the motor has been arranged to run continuously in one direction, the reversing being done by mechanical means, such as a friction reversing clutch or crossed belting; but these methods are now seldom employed, the modern practice for electrical winding engines being to use either one or two series motors geared direct to the winding drums and controlled in speed by resistances in the main circuit. The series motor, owing to its great starting powers and capacity for overloads, seems specially adapted for this class of work. For large engines, two motors are used so as to take advantage of the more efficient series-parallel system of control.

Brakes.—Rheostatic braking is frequently employed in connection with these winding engines, as also a mechanical brake electrically operated by means of current supplied by the motors when running as generators. But perhaps the most common type of brake used is the magneto-electric. This is simply a mechanical brake actuated by a spring or weight, but in which the brake shoes or strap are kept off the disc by an electromagnet in series with the main current, so that the brake acts when this main current is broken, and the shoes are lifted the instant the circuit is made.

Speed.—A common speed for electric hoisting from depths up to 500ft. may be taken as between 200ft. and 250ft. per minute, and the net load somewhere in the region of one ton, 20-h.p. to 25-h.p. motors being employed for this purpose.

Cost of Plant.—At the present time the price of electric winding gear may be taken to be about double that of equally powerful compressed-air engines, but owing to the poor efficiency of the latter, especially for engines so situated that the air cannot be reheated before use, and also owing to the greater ease with which the electric plant can be shifted and fixed at different points in the workings, electricity is fast superseding its older rival in this field.

Locomotive Haulage.—The advantages of the locomotive system of haulage over rope haulage, especially for surface work where the gradients are such as can be managed by locomotives, are the greater simplicity of working and improved efficiency, as well as the decrease of maintenance cost due to the elimination of the numerous sheave wheels, rollers, and other mechanisms peculiar to the rope system. As locomotives are made with a wheel base which will admit of operation on curves of radii as short as 15ft. they form a very flexible method of haulage, indeed, but so much depends on the grades and loads to be hauled that, as mentioned previously, this method cannot be recommended offhand without studying the local conditions. It need hardly be mentioned that the trolley system with bare overhead conductors and rail return is the only one to be employed for practical locomotive haulage, any attempt at

Digitized by Google

surface-contact or conduit systems being out of the question. Where the continuous-current system is adopted the locomotive is equipped with a series-wound motor or motors, the regulating switchgear being of the ordinary tram controller type. If two motors are used, as becomes necessary when the power is considerable and the gauge narrow, it is advisable to adopt series-parallel control. The motors are always of the *enclosed type*, but as the load is of a very intermittent character, being on the average much less than the maximum, the heating difficulties usually encountered with enclosed motors are not serious in this case.

Rating and Efficiency.—A common system for rating these motors is based on a temperature rise of about 75deg. C. after one hour's run at the rated load. A motor rated in this way will run sufficiently cool on actual service. The efficiency of these motors with gearing at rated load may be taken as at least 77 per cent. for the smaller sizes and 80 to 82 per cent. for 30 b.h.p. motors.

Three-Phase Locomotive.—When the power supply is by three-phase currents, it is necessary to have two insulated conductors, which slightly complicates the case. The motors used are always of the induction type, and, in order to provide for speed regulation, the rotor winding at three points is brought to collector rings for the purpose of inserting an external resistance in the rotor circuit. By this means any required speed regulation may be obtained at about the same efficiency as with the continuous-current motor controlled by series resistances. The behaviour of these motors at starting and under overloads is not quite so admirable as that of the series direct-current motor, but, on the other hand, the absence of a commutator and the inability of the motor to run at a speed much above that of synchronism, are two decided advantages in favour of three-phase motors for locomotive work.

Tractive Effort.—Generally speaking, the draw-bar pull required per ton for mining work is about 35lb. on the level, but for surface haulage 25lb. per ton should be sufficient on a moderate track. In either case about 22lb. per ton should be added for each per cent. of grade. The draw-bar pull exerted by the best mining locomotives, weighing from two up to six tons, may be taken as about one-eighth of the weight of the locomotive. From seven to ten tons about one-sixth of the weight may be taken as draw-bar pull, this fraction, of course, increasing as the weight of the locomotive goes up.

Weights, etc., of Locomotives.—Tables I. and II. give particulars as to gauge, draw-bar pulls, weights, etc., of a standard line of mining locomotives, and from which it can be seen that a locomotive weighing 8,000lb. gives a draw-bar pull on the level at eight miles an hour of 1,000lb.—that is, one-eighth of the weight—whilst the same locomotive on a grade of 1 in 50 gives 840lb. pull only. Taking the above figures in conjunction with the data given in the tables, we find that this locomotive weighing 8,000lb. will draw a load of 50 tons, or 25 two-ton wagons at eight miles per hour on the level (surface haulage), whilst 11 such wagons will load it on a 1 per cent. grade; seven wagons on a 2 per cent. grade, and on a grade of 3 per cent., nine tons or, say, four wagons only can be attached at this speed. It is evident from these figures that, as mentioned above, when heavy grades have to be negotiated locomotives are not serviceable, and one or other of the rope systems of haulage should be used.

Gauge.—The minimum gauge for the above 3½-ton locomotive when fitted with one 20-h.p. motor is 36in., but this can be reduced to 18in. when two 10-h.p. motors are employed, and the lightest rail which should be used is about 12lb. per yard.

Comparative Cost.—With regard to the cost of haulage by electric locomotives compared with animal haulage, it is difficult to arrive at exact figures. Taking, however, the results of a few colliery haulage plants which have been published, we gather that on the average there is a saving in favour of locomotive haulage of quite 60 per cent. in the cost per ton, even when making an adequate allowance for interest on capital and depreciation of plant. These figures are for coal haulage, but there is no reason to doubt that equally good comparative results can be obtained by electricity at all other classes of mining work, including the recovery of gold. Too much stress cannot be laid on the importance of electric power in connection with Australian gold mining, as in addition to the economy in fuel and water already referred to, there is the great flexibility and ease with which electric power plant can be removed and re-erected when mines are found to be of poor value and have to be abandoned, as is frequently the case in that country.

TRAMWAY SIGNALS.

A new system of automatic signalling for tramways has been devised by Messrs. T. H. Jones and E. Rotter, of which the following preliminary details are all that can be given at present, owing to the patents not being yet completed

This system of signalling, as installed in the Portsmouth Corporation tramways, has now been at work some time, and the services of two signalmen at the portion of line shown in the photograph have been dispensed with, thereby making a considerable saving. It is now proposed to instal the system of signals at other points on the line where there are dangerous curves. On each end of a portion of line which is to be protected, or on which it is not possible or desirable for two cars to meet or pass each other, a signal is erected. This can be atttached to the tramway standard or other suitable support. It is provided with the usual semaphore arm and spectacles, the light for the latter being provided by incandescent lamps enclosed in the drum. On a car approaching the signal, and having stopped at a point determined (if a stop is necessary), the motorman, on putting on his controller to start the car (if the line is clear), the semaphore arm of the signal in front of him will lower, showing a green light at night; at the same time the signal at the far end is locked in a horizontal position, and red light at night indicating danger, or that the line is not clear. It may be mentioned that these arms are counterweighted to return to the danger position, as required by the Board of Trade.

Having lowered the arm (if the line is clear) the car passes on its way over the portion of track, at the end of which, having stopped (if a stop is necessary), the motor-

Digitized by Google

man again puts on his controller to proceed on his way, which action unlocks the signal at this end. The system is also arranged to be worked as a "lock and block" system, that is, only allowing one car on the portion of line at the

Fig. 1 illustrates the car having lowered its signal passing on its way. Fig. 2 illustrates a car waiting, having been held at danger by the signal which has been locked by the car seen approaching around the corner. The system can

particularly. There are no movable electrical connections to wear, spark, or get out of order. In conclusion, it may be stated that this is the invention of Mr. T. Harison Jones, late of Toronto, Canada, who has had a number of years' experience in electrical engineering in America and abroad

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

489. What is the best system of guarding against explosions in gaseous coal-mines where it is necessary to use electric signals in a main haulage road, which is also the return airway?—P.

490. I have seen on a high-tension alternating switchboard of the receiving end of a power transmission plant an instrument indicating the number of cycles. I should like to have the theory of this instrument?—E. E. C. P.

ANSWERS.

Question No. 483.—Six 400-kw. machines connected across the outers in a three-wire station are on load; five of them are excited from the station 'bus bars, the sixth being a self-exciting machine. The armature bands of this self-exciting machine give way, and, jamming between the pole-pieces, earth the armature and blow the fuses on the main switchboard without affecting the + or - volts in the slightest. On examining the recording voltmeter cards afterwards a very slight drop is noticed a while before the main fuses went; at the point where the fuses did blow a slight rise is noticed. How can this be satisfactorily explained?—R. M.

Answer to No. 483 (*awarded* 7*s.* 6*d.*).—Presumably the preliminary drop in voltage was only of very short duration. It would commence at the instant when the short-circuit to earth occurred, and would continue until the fuses blew, and would simply be due to the large current flowing from the 'bus bars through the faulty armature to earth, causing the volts on the generators to drop, accentuated possibly by a slight fall in speed. As soon as the fuses went this overload would cease, and the station volts would rise to their old value, or even slightly above it, due to the engine governors permitting a slight momentary rise in speed when the load was suddenly reduced. In most cases, however, unless the load on the faulty machine happened to be very small at the time, the final voltage of the 'bus bars after the blowing of the fuse would be lower than before, due to the load of the six machines being thrown on to five machines. In any case, however, a momentary rise in volts might occur due to the imperfect action of the governors.—Q.

Answer to No. 483 (*awarded* 7*s.* 6*d.*).—The phenomena described by "R. M." are only those which would be expected, and are easy of explanation. We know that with any shunt-wonnd self-excited dynamo there are two paths open for the flow of the current from the armature, the first through the shunt coils, and the second through the outer circuit proper. Now, theoretically the value of the current which flows through these circuits will be $C_s = \frac{E}{R_s}$ and $C_e = \frac{E}{R_e}$ respectively, where E = the effective volts, C_s = the shunt current in amperes, C_e = the current in amperes flowing through the external circuit, R_s = the resistance in ohms of the shunt coils, and R_e = the resistance in ohms of the external circuit. From these equations it would appear as though these two currents were entirely independent of each other, but in practice this is not the case, and if R_e is made very small and R_s large, the distribution of the flow will not be exactly as $\frac{E}{R_e}$ to $\frac{E}{R_s}$.

This can be rendered self-evident by taking an extreme case. Suppose $R_e = 0$ and R_s = infinity − 1, then all the current will flow through the external circuit and none through the shunt coils. A further proof, if one is necessary, lies in the fact that every dynamo designer knows that it is impossible to excite a shunt dynamo, not only if the machine is shorted on itself, but also if the external resistance is so low as to "drain" the shunt of its due proportion of current.

Admitting the truth of the above assertions, it is easy to anticipate what would occur in the case given. Shortly before the fuses blew the armature was earthed, and owing to the earth on the system an excessive current was generated. Now, it does not materially affect the result how this current was absorbed, whether through an outer circuit or through a short-circuited armature; in either case the same conditions obtain. There is a much easier path for the current than through the shunt, hence the current through this circuit is to a certain extent weakened, and the volts drop to that extent. Immediately afterwards the main fuses flow, and the effect is the same as putting a very high, or infinite, resistance in the easy path; the shunt then takes again its normal current and the volts rise.

The above is the simple electrical explanation, but this is further complicated by the action of the engine. The E.M.F. depends not only on the forward induction, but also on the speed. When the earth developed, a heavy load was suddenly thrown on the engine, and probably it appreciably slowed down. When the fuses blew, the load was as suddenly removed, and the engine speed would increase. These two causes would be ample to fully account for the phenomena recorded.—M.

Answer to No. 483 (*awarded* 5*s.*).—When the armature bands gave way and caused the armature winding to make contact with the pole-pieces, it is very likely that some of the armature turns would be short-circuited, and thus the E.M.F. generated by the machine would be lowered. Although the point is not noticed in the question, it is very probable that the speed would be somewhat reduced. This would cause a further drop in the voltage of the dynamo. Thus the fuses would be blown by a return current from the 'bus bars. Suppose the normal voltage at 'bus bars to be 225 and the main dynamo fuses arranged to blow at 2,500 amperes. We will take the armature resistance as ·005 of an ohm It will be noted that this resistance would be reduced if several turns of the winding were short-circuited. Then the difference required between the voltage of 'bus bars and that of the faulty dynamo to blow the fuses would be:

$$\begin{aligned} \text{volts} &= \text{amperes} \times \text{resistance} \\ &= 2{,}500 \times \cdot 005 \\ &= 12 \cdot 5. \end{aligned}$$

i.e., fuses would blow when the volts at dynamo terminals fell to

$$225 - 12 \cdot 5 = 212 \cdot 5.$$

That there would be scarcely any drop on either side is quite to be expected, for the voltage at 'bus bars would be the mean of the potential of the six dynamos. The volts at terminals of damaged machine would fall, more or less quickly, to, say, 212·5, which is the figure we have already taken that would cause fuses to blow. The voltage at 'bus bars would then be

$$\frac{(5 \times 225) + 212 \cdot 5}{6} = 222 \cdot 9.$$

The relief to the other dynamos when the fuses went would probably cause a slight rise in volts, but this should at once fall to the normal.—M. M.

Answer to No. 483 (*awarded* 5*s.*). — The following hypothesis may serve as a possible explanation of the accident detailed in the question. The machine which failed was connected, in common with five others of equal power, to the outers of a three-wire system. The frame being earthed, as seen from the question, it was thereby virtually connected to the middle wire. When the armature bands broke they connected some part or parts

Digitized by Google

of the armature, in every probability positive or negative to earth, to the middle wire. Hence on the machine, there would be insufficient back E.M.F. between this artificial neutral point and, say, the positive terminal to balance the 'bus voltage, and a rush of current would set inwards to the generator. On the other pole the machine volts developed between the earthed point and the terminal would be, assuming that the armature bars were not short-circuited on themselves as well as being connected to earth), in excess of the voltage between the 'bus bars and earth, and a rush of current would flow outwards. Half a revolution later (in the case of a multipolar, half a magnetic cycle in the armature later) the excessive voltage would be directed to the positive side, and the current would reverse and flow out to the positive; similarly, the direction of flow would be reversed in the negative. We have then a heavy oscillating current developed, which would be sufficient to blow the fuse on each pole. It is apparent that, as the number of oscillations would probably be of the order of 25 per second, the recording voltmeters would not show the rapid variations of voltage consequent on the additions and abstractions of current, but would indicate the mean of these values of 'bus-bar voltage on the positive and negative side, and the volts would appear to be unaffected.

As regards the slight drop in voltage some time before the accident occurred, one is disposed to regard that as an independent circumstance, due possibly to some external load having come on. The same suggestion may be offered as regards the rise when the fuses blew. It is impossible that the withdrawal of part of the generating power should fail to produce a drop, unless the external load also went off, or the other generators had their fields strengthened at the same time. The only other suggestion is that the self-excited machine was motoring. This might also account for the drop noticed previously.—S. A. J.

Question No. 484.—In an Allis three-line engine of 4,000 h.p., driving a traction generator, the diameter of the shaft is increased in each successive line approaching the armature. Is this practice to be recommended as sound engineering? State reasons for or against.

Best Answer to No. 484 (*awarded* 10*s.*).—The statical stresses to which a shaft of the above type is subjected are (1) twisting moment, (2) bending moment, (3) shearing stress. The relation between the diameter of an engine shaft as above and the maximum twisting moment to which it will be subjected under working conditions is expressed by Rankine as follows:

$$d = \sqrt[3]{\frac{T}{f} \times 5{\cdot}1},$$

where d = diameter of shaft, T = maximum turning moment in inch-pounds, and f = 8,000 for wrought-iron solid shafts above 10in. in diameter. The bending moment exerted upon the shaft depends upon the distance from the main bearing at which the pressure upon the crank-pin is applied. This distance is usually measured from the edge of the main bearing cap. Rankine combines the twisting and bending moments in the following formula:

$$T_1 = M + \sqrt{T^2 + M^2},$$

where T_1 = what he terms the "equivalent twisting moment" and M = bending moment in inch-pounds.

$$\text{Hence} \qquad d = \sqrt[3]{\frac{M + \sqrt{T^2 + M^2} \times 5{\cdot}1}{8{,}000}}.$$

The factor 8,000 will be sufficient to cover any shearing stress which the shaft will be called upon to withstand. Let us now investigate separately the actual torsional stress transmitted through each journal of the shaft in question. The engine indicates 4,000 h.p.; assume that the stroke is 5ft., and that the engine runs at 90 revolutions per minute.

Then mean twisting moment =

$$\frac{40{,}000 \times 33{,}000}{5 \times 3{\cdot}1416 \times 90} \times 30 \text{ inch-pounds} = 2{,}800{,}000 \text{ inch-pounds.}$$

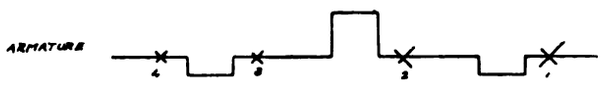
It may be also assumed that the mean turning moment on each crank

$$= \frac{2{,}800{,}000}{3} = 933{,}333.$$

The maximum twisting moment in a three-throw crankshaft, with the cranks at 120deg., is assumed to be (mean twisting moment × 1·05) by Rankine. It will be nearer the truth, however, if we assume maximum twisting moment of each crank

$$= 933{,}333 \times 1{\cdot}4 = 1{,}306{,}666 \text{ inch-pounds.}$$

Now, supposing that the engine has four main bearings arranged, as in sketch, and numbering them 1, 2, 3, 4,



beginning at the end farthest from the armature, the twisting moment at No. 1 journal is simply that necessary to revolve it in its bearing, and possibly to turn an eccentric. The twisting moment at No. 2 journal = that exerted through the high-pressure crank-pin by the steam on the high-pressure piston = 1,306,666 inch-pounds. ∴ diameter at this point of the shaft should theoretically be (neglecting bending moment)

$$\sqrt[3]{\frac{1{,}306{,}666 \times 5{\cdot}1}{8{,}000}} = \text{(say) } 9\text{in.}$$

Twisting moment transmitted by journal through No. 3 bearing is that due to the effort of both high and intermediate pistons and diameter

$$= \sqrt[3]{\frac{1{,}306{,}666 \times 2 \times 5{\cdot}1}{8{,}000}} = \text{(say) } 12\text{in.}$$

Twisting moment transmitted by journal through No. 4 bearing = full turning moment exerted by engine

$$1{,}306{,}666 \times 3 = 3{,}919{,}998.$$

∴ diameter of journal

$$= \sqrt[3]{\frac{1{,}306{,}666 \times 3 \times 5{\cdot}1}{8{,}000}} = \text{(say) } 13{\cdot}5\text{in.}$$

Thus it is evident that, so far as the torsional stresses in the shaft are concerned, the practice of increasing the diameter of a two or multiple throw crankshaft toward the end where the power is given off is supported by theory. The above figures do not, of course, take into consideration the bending moment due to pressure on crank-pin, and these bending moments can be worked out only when the positions of the main bearings are known.

The Board of Trade, Lloyds, and the British Corporation give formulæ fixing the smallest diameter of crankshaft which they will permit, so that the shaft is generally made of the same diameter throughout. For instance, Lloyds give a formula determining the diameter of the intermediate shaft, which, of course, transmits the full turning effort of the engine, and then stipulate that the diameter of the crankshaft shall be at least $\frac{21}{20}$th that of the intermediate shaft. In most marine three-line engines having crankshafts above 10in., the crankshaft is made in three sections, which are coupled together. When these are made interchangeable there is the advantage that if the low-pressure section shows a serious flaw in a foreign port it can be interchanged with the high-pressure section, where it will have less work to do, or a spare section may be carried by the ship. In the engine under notice the bending moment due to the weight of the armature will alone require the shaft to be made stiffer at that end of the engine.

There is also another consideration which will sometimes fix the lower limit of the diameter of the shaft. It is advisable in the interest of cool running not to let the pressure between the crankshaft journal and the bottom bearing exceed 400lb. per square inch, and where there is not room to obtain these results by lengthening the bearings, it is sometimes necessary to increase the diameter of the shaft for the same purpose The Americans generally fit extra heavy crankshafts to such engines as are designed for electric traction, being evidently under the impression that these shafts are more severely stressed than those of marine engines of similar power and speed, which is a matter of opinion.

It may be said, in conclusion, that the practice under discussion of varying the diameter of the crankshaft,

Digitized by Google

though entailing complication and expense in the drawing office and works, and at the sacrifice of interchangeability (it being evident that more spare brasses, etc., must be stocked), has the advantage of giving a lighter shaft.—E. C.

Answer to No. 484 (*awarded* 7*s.* 6*d.*).—The practice of increasing the diameter of the crankshaft in each successive line approaching the generator is not in accordance with sound engine design. Although the section of shaft nearest the armature has to transmit the combined twisting moment of the three lines, and, therefore, theoretically should be of a greater diameter than the part of the shaft most remote from the armature, there are practical considerations that render the practice of increasing the diameter very undesirable. The shaft being of different diameters at each bearing puts all idea of interchange out of the question, which, although not a vital point, may be of the utmost importance in the event of a breakdown of one line and the necessity arising of working with two lines only, of course assuming that the ordinary practice of building large shafts in sections is adopted. Then, again, the bearings being of different diameters makes the wear down of the shaft very liable to vary considerably at each bearing owing to the greater wearing surface presented at the lines where diameter of shaft is greater. This unequal wear down would tend to throw the shaft out of line, thereby localising the bending moment and causing hot bearings at least, if not ultimate fracture, a very large proportion of broken crankshafts being due to this cause. Owing to the difference in diameter on each side of the cranks, the bending moment will be very unevenly distributed, and severe strains set up in the crank-pins. The manufacture of such an engine is rendered more costly, as a separate set of patterns would be required for each bearing, and the boring out and bedding in of the brasses and crankshaft becomes a more difficult matter, and more liable to error than in the ordinary engine. Finally, the fact that no English engineers adopt this practice, even where lightness is of the first importance, as in warships, speaks for itself. The only gain to be had by varying the diameter of the crankshaft, is a saving in the weight of the shaft, which is a very doubtful gain, indeed, when the terrific strains set up at times of short-circuit and water in the cylinders are considered.—T. R. O.

Answer to No. 484 (*awarded* 5*s.*).—From the point of view of good scientific design the practice is a good one. This is readily made obvious if the torsional stresses in the shaft are considered. Calling the "line" furthest from the armature No. 1, the next No. 2, and the third No. 3, we see that in No. 1 the shaft has only to transmit the power of line No. 1, while in No. 2 it transmits the combined powers of Nos. 1 and 2, and in No. 3 it transmits the power of the whole three. It is therefore clear that the shaft need not be as large in line No. 1 as in No. 2, and in No. 2 as in No. 3. Of course, the stresses set up in the shaft due to bending are to be considered. These will be about the same in each engine, however, and they therefore do not affect the previous result in any way, except to thicken up the shaft.

There are several advantages resulting from the above arrangement which are very pronounced in a *large* engine of the character mentioned in the question. Chief among these are economy of construction—as regards material—and less weight of the moving parts.

Against these may be advanced several disadvantages. In a case where the crankshaft is in three pieces, connected by couplings, and where spare parts have to be supplied in the case of breakdown, it undoubtedly reduces the number of spare parts by uniformity in the construction of the engine. For instance, if each part of the crankshaft was made the same, only one spare crank need be kept, whereas if the shaft in each successive line was reduced in diameter, a whole crankshaft would have to be kept. If the shaft is very different in size at successive bearings, it would necessitate the bearings being slightly different in construction. This would, under some circumstances, prove to be a decided disadvantage. In the case of an engine of 4,000 h.p. standardisation is not an element of great importance, and whereas in the case of a small engine a good deal would be sacrificed to gain an uniform size of parts, under the conditions stated the probability is that what would be aimed at would be "as low as initial cost as possible compatible with a good engine." The "low initial cost" in a large engine would be obtained more by economy of material than by standardisation.—T. T.

INTERNATIONAL TRAMWAYS AND LIGHT RAILWAYS CONGRESS.

Particulars are to hand of the arrangements for the holding of the twelfth International Tramways and Light Railways Congress at the Berner's Hall, Agricultural Hall, Islington, in the week opening Monday, the 30th inst. The Right Hon. G. Balfour, President of the Board of Trade, will open the congress at 12 noon. A large and influential reception committee is being formed, and invitations to the opening ceremony will be issued by them in the names of the Union Internationale Permanente de Tramways and of the Tramways and Light Railways Association. The headquarters of the committee will be at De Keyser's Royal Hotel, Thames-embankment. Immediately after the opening ceremony the official inauguration of the Tramways Exhibition in the Agricultural Hall will take place. On the evening of the opening day a *réunion* will be held at the Institution of Mechanical Engineers, the invitations to which will include a lady. The first meeting of the congress will be held at 9.30 a.m. on Tuesday, July 1, after which members will have the option of proceeding on one of the excursions arranged or of making an inspection of the Tramways Exhibition. In the evening the conversazione of the Institution of Electrical Engineers at the Natural History Museum will take place, to which members of the congress are cordially invited. On Wednesday and Thursday congress meetings will be held at the same hour, 9.30 a.m., and excursions made in the afternoon. The following are some of the excursions and visits which have been provisionally arranged: visit to the City and South London Electric Railway, and the power station; the Central London Railway, and the power station; the Waterloo and Baker-street Electric Railway, in course of construction; the London United Tramways, and power station; the London County Council tramways, in course of construction; the Islington municipal electric lighting station (the congressists will be received by the mayor and alderman, by whom they are invited to luncheon); Messrs. Crompton's electric works, Chelmsford, about 30 miles east of London. In addition to the above, arrangements are in progress for visits to the following and other places: the Bankside electric lighting station, in London; the Westminster electric station; the Westminster hydraulic power station; Messrs. Siemens's electric works at Erith; and Doulton's pottery works.

NEW COMPANIES REGISTERED.

C. E. and H. M. Peel, Limited.—Capital, £20,000. Objects: to acquire and carry on the business of C. E. and H. M. Peel, metal merchants, electrical, mechanical, and general engineers, etc.

Clubbe and Southey, Limited.—Capital, £2,000. Objects: to acquire the business of A. W. Southey, and turn to account certain patents; as mechanical, general, and electrical engineers, etc.

Foote and Milne, Limited.—Capital, £15,000. Objects: to carry on in all or any of their respective branches the businesses of electrical, mechanical, and general engineers and contractors, brass and other metal founders; to acquire the business carried on by H. Foote, L. Milne, and E. J. Owen at 66, Victoria-street, Westminster, etc.

Pekin and North China Electrical Corporation, Limited.—Capital, £100,000. Objects: To acquire the business heretofore carried on by the Siemens und Halske Actien-Gesellschaft, Messrs. Mandl and Co., and the Chinesische Electricitäts-Gesellschaft, M. B. H., and to carry on business as electrical engineers, and builders of electric plant, and contractors at Peking, in the empire of China, with all or any the assets and liabilities of the proprietors thereof; to adopt an agreement made between the Syndicat du Yunnan Tel of the one part and the Peking and North China Electrical Corporation, Limited, of the other part, and to carry on the business of generators, accumulators, and distributors of electrical energy for the purposes of light, heat, or power; as manufacturers of all plant and apparatus, cables, wires, lines, motors, generators, dynamos, accumulators, transformers, lamps, plant, and machinery, etc.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
ther Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXVII., bound in blue cloth, gold lettered price 8s. 6d.

"ACCOMPANIED BY COPIES OF THREE RECENT TESTIMONIALS."

The above is what generally constitutes the concluding sentence in almost every advertisement emanating from either a municipal, technical, or district council, when requiring the services of some person to fill some position which has become either vacant or created under the council. Whatever the correct interpretation of the above fashionable phrase may be, is perhaps known to some of the councils in question. Nevertheless, very many who are desirous of competing for the positions to which this term is attached do not know what is required; consequently they allow their conscientiousness, or probably pride, to prevent them going round begging for such testimonials, eventually sending applications which do not rigidly conform to the specified regulations. The result is the informal applications are often consigned to the waste-paper basket, and many a good man is compulsorily retired. With regard to the term itself, it surely cannot mean that the candidate desired should have been in three similar situations recently, for then the mere fact of possessing the regulation copies would be sufficient proof that the man was either a natural gad-about or an inefficient workman, who neither desires nor has opportunity of staying long in any situation. Probably, however, the meaning of the term is that testimonials from three separate individuals in the same establishment or locality is sufficient. If that is the case, it gives a great advantage to those candidates who have the mean audacity to ask everyone directly or remotely connected with the works in which they have been employed for a testimonial. Even if the above should be the correct meaning, one testimonial from some person in authority who is really acquainted with the abilities of the applicant would convey the same, if not a greater amount of truth than threefold testimony. Whatever is the proper interpretation, the practice certainly caters for those gentlemen who make it their business to collect testimonials from all sources, getting them typewritten, together with dozens of copies, in order to sort them out to suit particular situations for which they apply, in the hope that they may by chance be selected for a good position irrespective of their true abilities. Of course, whatever these abilities turn out to be, the council or firm in question are in a position to say the man had good testimonials. And in the case of a council, it would be too much an exhibition of weakness to dispense with the services of someone whose abilities were not found to tally with the testimonials shown. There are, however, two sides to the question The fault does not wholly rest with the recipients, for the persons who give testimonials always have the power, if not the discretion, to refuse. Unfortunately there is a good deal of "human nature in man," and when one of these testimonial hunters asks for a testimonial, the hearer either feels flattered to think that a word from him will go a long way—"which in this case is a fact"—or from the desire to improve the man's position he does not care to say no. Many electrical engineers keep a good supply of typed and copied testimonials because they are fully aware that little notice will be taken of their applications if not accompanied by these advertisements, being thereby forced to become testimonial hunters. A great mistake is in the flippant manner in which the term "electrical engineer" is used. For example, a person goes to either fit up or repair an electric bell, probably in the residence of a councillor. When finished he has the presumption to ask for a testimonial to assist him in obtaining some particular situation. On the face of it this

Digitized by Google

seems a small request, and it is consequently complied with. He is thus recommended, by the aid of this testimonial, to some person or council who require the services of an electrical engineer, and this document, being signed by an alderman, will carry more weight when sent to a council than half a dozen coming from a private firm, however much the latter may be better acquainted with the meaning of the appellation "electrical engineer." More lasting satisfaction would be given to both parties, with a slightly increased initial trouble, if references only were required. Few employers at the present day object to men trying to improve their position. Thus by referring to a firm or council for whom the applicant has worked, a better knowledge of his capabilities will be obtained and a better choice made, for it is a by-word among "electrical engineers" that the actual ability of a man varies inversely with the number of testimonials he carries.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

AIR-PUMPS.

SIR,—I notice in the current issue of your paper a note pointing out some "glaringly misleading statements" in my reply to Question No. 478. If your correspondent, "E. Cosgrave," will refer to his standard book (Seaton's "Manual of Marine Engineering," which he recommends), he will find on p. 230 the words, "With a jet condenser a vacuum of 24in. is considered good, and 25in. as much as possible." This, of course, refers to the usual type of jet condenser, shown well in my outline sketch, which has so raised "E. Cosgrave's" ire. The air pump is *usually a horizontal double-acting one*, and may be worked either from the main engines or from an auxiliary one, as is done in the Worthington, Blake-Knowles, Klein, and Smith-Vaile jet condensers.

I am quite aware that with special constructions, such as the Klein barometric jet condenser, better results may be obtained, but I should say a vacuum of 27in. is an exceptional thing, even with them.

Secondly, I cannot imagine what is wrong with the term "leaks in." Surely all the air must have leaked in from somewhere, either with the condensing water or through leaky joints.

Thirdly, the diameter given for the air-pump barrel is alleged to be too small. This dimension is obtained directly from the efficiency of the pump, which I have taken as 50 per cent. Seaton, on p. 247, gives the efficiency as ·6 to ·4, so that my figure is just between the two. The valve area I did not give, as it depends on the type of valve used, but I did give the limiting velocity through the valves as 10ft. per second, which is good up-to-date practice. The velocity through the foot and head valves may, perhaps, be a little less than this, as the space is not so restricted as with the bucket valves.

Fourthly, it is certainly true that double-acting pumps have a lower efficiency than single-acting ones. This is due to the fact that the direction of motion of the water and air is constantly being reversed, whereas in a single-acting pump it is always in the same direction. The difference in efficiency, however, is not very great in well-designed pumps (Seaton gives the limiting values as ·6 and ·5 respectively), and the point was omitted in my reply.

I think, Sir, I have shown that the statements given in my reply were substantially correct, and, in conclusion, I think it would be better if in future "E. Cosgrave" would take the trouble to inform himself more carefully of the matter under discussion before launching out into print; he may then avoid showing his "charming ignorance" of the subject.—Yours, etc., T. SQUARE.

THE GENERAL ELECTRIC COMPANY.

SIR,—The General Electric Company (1900), Limited, wish to express their unqualified regret at the terrible results which attended the fire at their premises on Monday, the 9th inst., and to state that they are taking steps to give this sentiment practical shape. They would also like to take this opportunity to convey to their friends and customers their thanks for the many expressions of sympathy received in letters, telegrams, and personal enquiries, and to inform them that the part of their premises which was involved is small. Business will be carried on exactly as before, and it is hoped that if at first one or two delays may have occurred the firm will receive indulgence on this account.—Yours, etc.,

THE GENERAL ELECTRIC COMPANY (1900), LIMITED.
(M. Bing, Managing Director).

London, E.C., June 11, 1902.

[N.B.—We have decided to defer all detailed reference to the above lamentable fire till the facts are given at the inquest.—ED. *E. E.*]

INSTITUTION OF ELECTRICAL ENGINEERS.

The following is a copy of a letter, which is being circulated amongst the members of the Institution of Electrical Engineers, dealing with the important question of the subscriptions. It behoves all who belong to this Institution to look into the figures here given, so as to be able to express their opinion when the matter comes up for discussion. We have taken the trouble to average out the rates which are given in the addendum, and find that there are, roughly, 3,500 members of all classes whose average contribution to the Institution is £1. 15s. per member per annum. This is considerably below the average figure for new members, owing to the fact that there are a large number of old subscribers whose rates have not been increased of recent years. A perusal of the accounts of the Institution for the past years, however, will show that there has always been a very considerable surplus, which is now being added year by year to the building fund. This building fund is also being urged as a reason for increasing the subscriptions of all classes of membership. We think that it would be well to remember that the first object of the Institution is the good of its membership, and that this is not strongly connected with the housing of the parent institution in a building which would never be used by the majority of the members, and only by the London members in the winter months. In fact, the load factor of all such buildings is a very poor one, such as a borough electrical engineer would not make much capital expenditure to obtain. The letter reads as follows:

Dear Sir,—For a considerable time past it has been apparent to your Council that an increase in the amount of the subscriptions of all classes of members has, in view of the largely extended influence and work of the Institution, become imperative, and they are strongly of opinion that such increase should apply not merely to the subscriptions of future members, but also to the future subscriptions of existing members.

They have carefully considered the case of those members the amount of whose subscriptions remains the same as they were during the early life of the Institution, and they believe that the postponement until now of any increase therein will, in the interests of the Institution, be regarded by them as a sufficient consideration for their support in the days when the Institution was but a small society, and the expenses were consequently light.

In arriving at the above conclusion, your Council has been largely influenced by the pressing, and, indeed, unavoidable necessity, for the provision of suitable accommodation for the Institution by the rapid extension of the system of local sections at home and abroad, and the consequent enlargement of the *Journal*, by the issue of *Science Abstracts*, and by the steps that have to be taken to give effect to the general desire that the standards of qualification for the admission of all classes of members should be high.

To meet these needs it will be necessary that the following subscriptions, irrespective of the member's place of

Digitized by Google

residence and of the date of his election, should be paid in future by all: (1) members, three and a-half guineas per annum; (2) associate members, two and a-half guineas; (3) foreign members, two guineas; (4) associates, two guineas.

In recommending the proposed increase the Council relies upon your approval, confident that every member of the Institution is prepared to support steps requisite to meet this increased expenditure.

Appended is a statement affording some data in relation to the present amounts of subscriptions, receipts, and expenditure per member, together with other information which it is thought will be of use in enabling members to realise the position

The Council will, in due course, submit to a special general meeting of members, as prescribed by Articles Nos. 54 and 56 of the articles of association, the scheme for giving effect to their proposals, and the alterations in the articles of association which will consequently be necessary.

I am directed to express a hope that the Council may receive from you, as soon as possible, any remarks you may wish to offer on the subject.

The fact that the building fund now amounts to over £10,000 prompts the Council to anticipate an early realisation of their wish to provide a permanent home for the Institution.—I am, dear Sir, yours truly,

WALTER G. MCMILLAN, Secretary.

Statement giving Information as to Existing Income and Expenditure.

At present there are on the lists, approximately:

Of *Members*—120 who pay only £1 per annum, 285 who pay two guineas, 180 who pay £3, 155 who pay three guineas.

Of *Associate Members*—110 who pay only one guinea per annum, 785 who pay two guineas.

Of *Foreign Members*—135 who pay only £1 per annum, 15 who pay only one guinea, one who pays two guineas.

Of *Associates*—185 who pay only £1 per annum, 375 who pay only one guinea, 445 who pay £1. 10s., 700 who pay one guinea and a half.

The lowest estimate of the cost of conducting the affairs of the Institution on the present scale and under the present limitations to its usefulness, shows an expenditure per member, including students (whose subscriptions it is not proposed to raise), of nearly 30s.

This expenditure provides no margin for the normal increase, which is unavoidably progressive, or for contribution to those demands which must at no distant date attend the provision of suitable Institution premises.

It should also be pointed out that between 1894 and 1901, while the average revenue per member including all classes has increased by 4s. per annum, the expenditure per member has increased by 8s.

It is further worthy of note that, while the expenditure per member of this Institution is at present approaching 30s., that of the Institution of Civil Engineers appears to be about 57s., and that of the Institution of Mechanical Engineers 54s., and the subscriptions to these institutions are largely in excess of the averages of those now in force in the corresponding classes of the Institution of Electrical Engineers.

FORTHCOMING EVENTS.

FRIDAY, JUNE 13.

Royal Institution.—At 9 p.m., Mr. G. Marconi on "The Progress of Electric Space Telegraphy."

Physical Society.—From 3.30 to 6 p.m., visit to the National Physical Laboratory, Bushy House, Teddington. Trains leave Waterloo (south station) at 2.36, 3.14, 4.15; and Waterloo (Windsor line station) at 2.40, 3.17, 3.40.

TUESDAY, JUNE 17.

Institution of Junior Engineers.—Visit to the Globe Rope Works, East Ferry-road, Millwall, E.

WEDNESDAY, JUNE 18.

Institution of Electrical Engineers.—At 12 noon, deputation to the President of the Board of Trade on subject of electrical enterprise.

Royal Meteorological Society.—At 4.30 p.m., ordinary meeting.

THE ELECTROLYSIS OF GAS-MAINS.*

BY JAMES SWINBURNE, M.I.C.E.

Argument: Tramways and telephones—Cross's Committee—Parliament considered forbidding earthed returns greater hardship to tramway industry than chance of electrolysis to pipe companies—Should tramways be liable for damages due to electrolysis?—Little definite information as to real damage by electrolysis available—Explanation of anode and cathode—Corrosion at anode only—Methods of minimising corrosion—Measures to be taken by pipe companies—American electrolysis—Natural earth currents.

About 10 years ago there was a good deal of friendly friction between the National Telephone Company and the electrical traction industry. Electrical traction was just beginning to develop in this country at that date; and electrical engineers were promoting Electric Tramway Bills in Parliament. The telephone people complained that the leakage, or stray currents, from the tramways disturbed their telephone systems; and they asked for protective clauses. In some cases such clauses were inserted, and in others the telephone people failed. In one case the committee, in their anxiety to be quite fair, ruled not only that the tramway must not disturb the telephones, but the telephones should not disturb the tramways. The whole question became very acute when the National Telephone Company sued Graff Baker and the Leeds Tramway Company for disturbing their circuits in Leeds. This action was heard by Mr. Justice Kekewich, who decided that the Telephone Company could get no damages because the tramway people worked under an Act of Parliament, and were not negligent, but were doing the best they could in reason.

A joint committee of both Houses of Parliament was soon appointed to go into the whole question. This committee discussed the telephone question very fully, and finally decided broadly that, as the telephone circuits could be easily protected by doubling, instead of using earth return, and that as they were adopting this metallic return anyhow, because it gives a better service, they should not have the protection they sought. The gas and water companies, however, also appeared in this enquiry; and this was practically the opening of a question which has awaited satisfactory settlement for the last decade. This committee—generally known for short as Lord Cross's Committee—decided that uninsulated returns are permissible, and that preventing their use would throttle the industry. But they also decided that the tramway people should take all reasonable precautions in building and working their undertaking, so as not injuriously to affect by fusion or electrolytic action any gas or water pipes.

Since this recommendation there has been little done by the gas and water companies until recently. Electrical tramways are now being put down on such a large scale that the owners of underground pipes are naturally beginning to regard the whole question as being very serious. When we consider the capital value of the buried pipes in this country alone, which must run into very many millions of money, it is clear that the question whether they will be eaten into holes and destroyed by tramways, without either means of prevention or redress, is of enormous importance.

The first question was whether tramways should be allowed to have leakage currents at all. Parliament practically decided that as it was a very great convenience to tramways to have what is called an earth return, and as the corresponding harm to other people was small, they should be allowed to have earth returns—that is to say, the gas, water, and telephone companies are not to have immunity. The Telephone Company is not on all-fours with gas and water companies, as the National Telephone Company was not incorporated by Act of Parliament.

During last session the controversy between the tramways and the gas and water companies was substantially that the tramway people said they caused no damage to the pipes, or none that would ever be perceptible; and Parliament had already decided that they should be allowed to use earth returns. The pipe owners said, "We do not want to stop your use of the earth return. You say it does us no harm. We do not know whether it does or not; but we fear it may. We therefore ask you to be liable for damages if you eat our pipes. If you do not eat them, such a protection, while satisfying our fears, does you no harm, and if you do destroy our property it is only fair that you should indemnify us." The tramways said: "We will not hurt your pipes, and it is unfair that if your pipes are naturally corroded, or are corroded by some other tramway people, we should have to pay, for however carefully we guard against leaks we may at any time be made liable by the mistake of an arbitrator for a fabulous sum without having done any harm to you at all." The tramway companies also argued that they worked under the Board of Trade regulations, and that the Board of Trade regulations were designed to prevent corrosion of pipes, and were amply strict enough for the purpose. The pipe owners urged that there was always electrolysis, and the Board of Trade merely reduced it as far as was consistent with the satisfactory working of the tramways, without by any means rendering the tramways innocuous. This we may discuss more fully later. Last session the gas and water companies on the whole failed to get even the smaller protection they asked for, and this session they have done but little towards getting the insertion of clauses in their favour. Such is very shortly the history of the question.

When I was asked to give a lecture on this subject I was very undecided as to what sort of paper I had better give. I might give an elementary treatise on electricity, with special reference to electrolysis, or I might give a lecture full of experiments. Or I might have drawn awe-inspiring pictures of the future of your distribution systems, when all the iron of your pipes had been eaten away and the gas merely ran along the tunnels left in the ground. Or I might

* Lecture delivered before the Incorporated Gas Institute.

Digitized by Google

have urged the tramway point of view that the electrolysis is very minute, and what there is is rather good for the pipes, being a pleasant stimulant. An experimental lecture appeals to those present, and is, no doubt, more interesting in a way, but I felt that I had been honoured by being asked to deal with a subject which is of enormous importance to your industry, and therefore concerned many people who would be outside this lecture room.* I therefore concluded that you would probably prefer me to deal with the subject broadly, and try and give you as fair and full an idea as I can of the whole subject.

It is difficult, of course, to be impartial on such a matter; and you will no doubt regard me as being specially electrical. I am, however, also an old gas man, as I was for some time at the South Shields Gas Company's works, under Mr. Warner, whom you all know. In the various contentions I have appeared in the law courts, and in the committee rooms, sometimes on the electrical side and sometimes for the gas and water people. My views have thus been moderate, and I think fairly impartial; and I will do my best to be impartial in this paper.

But by far the greatest difficulty is to give any real information as to the true effect of the earth currents from tramways. The question from the technical or scientific side is very obscure. If pipes are being corroded—even if the corrosion goes on to a very serious extent—it may not show for a long time. In fact, corrosion would only show when considerable damage had been done, unless a pipe company happened to examine a pipe which was specially strongly affected. The only thing is for me to give as much information as I can.

Electrolysis, or electric separation, applies to electric separation of chemical compounds. The most familiar example is the electrolysis of water. If an electric current is caused in, say, acidulated water, the piece of metal which leads the electricity down is called the anode, or way down. The piece which leads the electricity up again is called the cathode, or way up. The two pieces of metal are called electrodes, or electric ways. The liquid is called the electrolyte, or thing that can be separated electrically. Water and solutions of salt are all electrolytes—that is to say, they are decomposed when there is an electric current, and a current cannot exist between metallic electrodes in an electrolyte without decomposition. The decomposition is strictly proportional to the current and the time. Thus when acidulated water is decomposed, the quantity of oxygen and hydrogen liberated depends on the current and the time it is on. The unit of current is an ampere, and an ampere decomposes 0·3357 grm. of water per hour, yielding 0·0374 grm. of hydrogen and 0·2983 grm. of oxygen. If, instead of water, other substances are decomposed, the amounts liberated are proportional to the combining weights. If the electrodes are platinum there is no corrosion, as the platinum does not easily form salts. Suppose, for instance, the solution, instead of being acidulated water, is water containing common salt and other salts, and suppose iron electrodes are used, then the anode will be converted into ferrous chloride. Hydrogen will come off at the cathode unless there is some metal that will deposit instead of it. Thus if we have copper electrodes in copper sulphate, copper will be eaten off the anode, forming copper sulphate, and copper will be deposited on the cathode, forming a fresh-coloured coating. This process is carried on on a huge scale in copper refining.

What we are concerned with is the corrosion of iron when used as an anode in the ground. In the ground in a town we may take it that the pipes are buried in earth or sand which is damp with salt and other compounds of sodium, potassium, and ammonium. Iron has a very curious property. It is not attacked when it is used as anode in an alkaline solution. In caustic soda, for instance, it is not touched. But this property is scarcely likely to help it in the ground, for even if the ground was slightly alkaline, an effect of the electrolysis is to render the region round the anode acid. The iron is thus attacked. If there is plenty of salt present, we get chloride of iron, but the chances are that the iron is converted into basic salts or oxides. It does not matter much to the pipe what it is converted into. No harm is done to the pipe where it forms a cathode, as the only thing that could happen would be that metal might be deposited. Iron could not be deposited under the circumstances, so that we need only consider the corrosion of the anode. As the combining weight of iron is 28, the consumption of iron per ampere is 0·00029035 grm. a second, or 20lb. a year.

It will be clear then, that a gas-gipe can only be corroded where it is acting as an anode—that is to say, where the electric current is leaving it to pass into damp ground. There is no corrosion where the electricity enters the pipe, because it is a cathode there, and there is no corrosion where the electricity leaves, unless it passes into an electrolyte such as damp earth. If the electricity is taken off by a metallic conductor, such as a wire, which is not an electrolyte, there is no corrosion.

(To be continued.)

* The lecture actually given was experimental and explanatory. As the same lecture does not both sound and read well, I practically prepared two.

THE SALFORD ENQUIRY.

Upon this enquiry being resumed, **Mr. C. R. Turner,** formerly electrical engineer of the Corporation, said he thought undue influence had been exercised in favour of the acceptance of certain tenders. In cross-examination, Mr. Turner admitted that while he thought that a report which was produced was intended by Mr. Clirehugh to help Galloways to obtain an order, he knew Mr. Clirehugh advised the committee to adopt engines of another type, and that, in fact, Galloways did not get the contract. He had been told by Mr. Clirehugh that Messrs. Galloway must have the job. He had ceased his opposition after having been told that "if he did not, it would be worse for him."

Mr. William Hunt, elective auditor for the borough, said that Messrs. Lacey and Clirehugh approved of Mr. Turner's plans and specifications at about £80,000. The present work would cost approximately £400,000, and the result was that there were 12 boilers and six engines lying idle, and likely to do so for some time to come. He suggested there were only two sets of people responsible—the consulting engineers and the Electric Light Committee. The Council could not be held absolutely free from blame, but the responsibility rested with the professional advisers of the Electric Light Committee. Mr. Hunt said he wished to protest against what had been done with respect to boilers, and also said that to place in the hands of Sir Richard Mottram the responsibility of conferring with the consulting engineers as to the type to be adopted was unjust to other firms afterwards invited to tender. Mr. Hunt proceeded to read from the minutes with a view of showing there had been delay in supplying what was required under the contracts, and that the material, such as that of motors, was not satisfactory. He did not suggest that the committee were endeavouring unduly to shield any contractors, but that they had not a due regard to the interests of the ratepayers. With regard to the works, he thought it would have been possible to avoid the closing of Walness-road, and to have supplied all the requirements, so far as electric traction was concerned, from the other stations.

Mr. S. V. Clirehugh spoke as to the employment of his firm as consulting engineers. In their first report they suggested that less money should be spent than was proposed in putting down the electrical plant. He denied that they were at any time prepared to carry out the scheme on Mr. Turner's specifications. There was no truth in the statement that he altered the report at Sir Richard Mottram's instigation. The latter had been opposed to the appointment of the witness. He had not stated that he had made the alteration at the request of Sir Richard Mottram. It was untrue that Sir Richard had influenced him in his recommendations. He denied that he had ever been approached directly or indirectly on behalf of Sir Richard Mottram with a view of improperly influencing him or of doing so on behalf of Mr. Haworth. He denied that he had made a statement to Mr. Wheatcroft as to Sir Richard Mottram. It was because of information which he had received that the witness had altered his report, and after a visit to Galloways. In a letter produced he had said he was prepared to make the works second to none in the country. This must no doubt have been to collaborate with Mr. Turner on his specifications. This scheme would have been second to none in cost as well.

The enquiry was adjourned.

On Saturday, when **Mr. Clirehugh** continued his evidence, he repudiated the suggestion that he had been influenced by Sir Richard Mottram in favour of Galloways, or that the latter firm had done anything out of the ordinary course of business.

Sir Richard Mottram explained that he took some interest in the matter of the undertaking owing to the letter from Mr. William Mather. As an engineer himself, however, he thought it was better for him not to interfere. He mentioned the matter to the Mayor and Mr. Alderman W. Robinson. At a meeting of the committee which he attended he did not go for the purpose of advocating Galloway's or any other firm's claims. He denied that he had advised in committee as to the acceptance of any tenders. He had spoken in favour of a particular type of engine. His presence on the occasion in question was due to special circumstances, and he did not attend at meetings afterwards when tenders were accepted.

Mr. A. Haworth, a former member of the Salford Council, said he was appointed chairman of the Electricity Committee of the Corporation when that committee was formed. He denied that he had told Mr. Turner there was a conspiracy to upset his specifications. He had given no information about Galloway's tenders, and he had no interest in regard to any; all that he wanted was to get the best for the Council. He no doubt did mention being "pestered" to Mr. Wheatcroft. He was pestered chiefly by men coming from the works and complaining.

Mr. W. E. Norbury, director of Messrs. Galloways, Limited, said it was part of his business to call on firms, and he had not done anything improperly to influence the orders of the Corporation. He had only seen Mr. Haworth on 'Change, and had tried to do business with him, but not in any underhand way.

Judge Parry said the charges against Messrs. Galloways had been withdrawn, and, as far as he could see, there was nothing whatever done by that firm that was wrong.

Mr. Wheatcroft said the cable contract of Messrs. Glover was not the lowest tender. He contended that the report made by the consulting engineers distinctly favoured Messrs. Glover as against the lowest tender, that of the British Insulated Wire Company. He did not blame Messrs. Glover, who were men of business. He added, in reply to Judge Parry, that the contract was obtained honestly. Mr. Wheatcroft further urged that the engineers had permitted Messrs. Glover to put down brick instead of stone troughs in the laying of the cables.

Mr. Turner contended that the report of the engineers was unequal and unfair to other tenderers besides Messrs. Glover. He went over the details mentioned in the report, and contended the contractors did not carry out the work according to specifications. He did not suggest fraud, but he said it was a loss to the Corporation.

Judge Parry intimated that he did not wish to hear anything which merely suggested error. No doubt mistakes had been made. If necessary, he would have an independent expert opinion to ascertain whether the contract had been carried out.

Mr. Cobbett having complained that the matter had been brought up after Mr. Clirehugh had left, the judge said he would ask Mr. Cobbett to send him a statement on this subject.

Digitized by Google

Mr. A. E. Tanner, managing engineer for Messrs. Glover, who had the carrying-out of the contract, said he suggested the change as to the troughing to Mr. Clirehugh. He did not think stoneware was any better than brickware to go underground.

Mr. W. Hunt, elective auditor, then gave evidence in support of his complaint that Messrs. Galloway did not deliver boilers in the time specified. He contended that Messrs. Galloway had departed from specifications in regard to the mouthpieces and the fittings of the boilers. The latter had been condemned by the Steam Users' Association on account of the material in them.

Mr. Galloway admitted the ground of the complaint as to the mouthpieces. The boilers were all ready.

Judge Parry said there was no suggestion of bad faith or of injury to the ratepayers. Messrs. Galloway had given a guarantee to put anything right.

Councillor Jackson was also called, and stated that Galloway's tender was £320 more than another firm's tender. He had understood that they would not tender. Their tender, however, was accepted. He did not approve of the invitations to certain members of the Electric Light Committee to a luncheon at Messrs. Galloway's on the occasion of the visit of the Iron and Steel Institute. He received an invitation, but did not go.

Judge Parry, in closing the enquiry, said he was strongly impressed with the evident desire there had been on the part of Messrs. Wheatcroft and Hunt to serve the public. He left Mr. Turner out of his reference, because his portion of the case might not be finished, and he did not wish to criticise. Having said so much for their portion of the case, he had been considering whether, as his report would take some time, it was not due to the other parties to make a statement. On one matter he had made up his mind with regard to Messrs. Lacey, Clirehugh, and Sillar that, though he did not think direct charges of fraud were made against them, there were certainly suggestions of fraud and ill-doing made which, while hanging over them, must be damaging. He had yet to go into much detail, and might have to say whether or not they had been guilty of irregularities. He had, however, come to the absolute conclusion that nothing like fraud, ill-doing, or undue influence was made out against them. He was prepared to say the same with regard to Sir Richard Mottram. He might have to report that Sir Richard was indiscreet, but between doing ill and making a mistake or an error of judgment, there was an enormous difference. He was able to congratulate the Corporation and the public on this part of the finding With regard to ex-Councillor Haworth and others, he found no evidence on which they were rightly to be charged with fraud, or ill-doing, or wickedness, or cheating of any kind.

TUBE BILLS IN PARLIAMENT.

LORD WINDSOR'S COMMITTEE.

THURSDAY, JUNE 5.

After sittings extending over several weeks the Select Committee of the House of Lords presided over by Lord Windsor concluded their labours. The whole of the day's proceedings was occupied with the consideration of applications for special clauses against the promoters of the Brompton and Piccadilly-circus, the Hammersmith, Piccadilly, and City, and the North-East London Railways.

Mr. Coward, K.C., brought up a clause for the protection of the Shaftesbury memorial fountain in Piccadilly-circus, and the clause was amended and agreed to. Mr. Coward then raised the subject of workmen's fares, and asked for what was known as "the Central London clause" to be applied to the whole of the undertakings of the Brompton and Piccadilly-circus and Great Northern and Strand Railways.

Mr. Littler objected to the clause, and the committee declined to impose it upon the companies.

The committee assented to special clauses for the protection of the Hippodrome.

Mr. Pember, K.C., for the London County Council, asked the committee to pass a clause providing that in no circumstances should any interference be ordered by any arbitrator with the gradients or position of the main or branch sewers of London.

The clause was rejected.

Mr. Pember pointed out that in Railway Bills it was customary to insert a clause providing that any objects of geological and antiquarian interest discovered by the railway company in the course of carrying on their works should be subject to the disposal of the County Council. He noticed, however, in one of the Bills, that this power was given, not to the County Council, but to the Borough Council. It was better that these objects should be collected in one special museum than that they should be distributed among 28 councils scattered all over the Metropolis.

The committee directed the clause to be so amended.

A number of other clauses were submitted on behalf of the London County Council, but rejected by the committee, **Viscount Knutsford** remarking that their acceptance would practically constitute the County Council the authority to manage the whole of the affairs of the companys.

Mr. Pember, at the conclusion of the consideration of the clauses, congratulated the committee on having brought their long labours to a close.

The **Chairman** thanked Mr. Pember for his congratulations, and, on behalf of the committee, acknowledged the assistance they had received in the conduct of the proceedings from the learned counsel engaged on both sides.

The clauses were subsequently gone through, and the Bills ordered to be reported to **the House for third reading.**

CREWE ELECTRICITY ACCOUNTS.

The accounts of the Crewe electricity works for the year ended March 31, 1902, show a total expenditure on capital account of £39,420. Abstracts of the revenue account and balance-sheet, and statement of electricity generated, sold, etc., are given below:

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Generation of electricity	1,230	10	5
Distribution of electricity	80	4	4
Public lamps	146	15	8
Rates and taxes	91	13	4
Management expenses	364	3	7
Special charges	7	13	0
Total expenditure	1,921	0	4
Amount carried to net revenue account	2,769	14	10
	£4,690	15	2

Cr. Income.	£	s.	d.
Sale of current per meter, less discounts	2,167	3	4
Public lighting	2,428	9	5
Meter rentals	51	15	10
Sale and repair of lamps and other apparatus	43	6	7
	£4,690	15	2

GENERAL BALANCE-SHEET.

Liabilities.	£	s.	d.
Loans received as per capital account	26,000	0	0
Less amount repaid	1,239	19	9
	24,760	9	3
Sundry creditors	434	19	9
Amount owing to treasurer on capital account	13,527	6	4
Less in hand on revenue account	472	1	11
	13,055	4	5
Net revenue account—balance at credit	948	16	4
	39,199	9	9
Balance—excess of assets over liabilities	1,239	10	9
	£40,439	0	6

Assets.	£	s.	d.
Amount expended for works as per capital account	39,420	11	5
Stores on hand	275	5	3
Sundry debtors for current and meter rentals	715	0	8
Other debtors	21	6	7
Cash in hand	6	16	7
	£40,439	0	6

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T. units		347,758
Quantity sold: Public lamps	182,535	310,505
Quantity sold: Private consumers by meter	127,970	
Quantity used on works		19,090
Total quantity accounted for		329,595
Quantity not accounted for		18,163
Total maximum supply demanded (kilowatts)		245

Number of public lamps: three arcs, 675 posts incandescent.

SHEFFIELD ELECTRICITY WORKS.

The report and statement of accounts of the Sheffield Corporation electricity department for the year ended March 25 last have now been issued. The capital expenditure amounted to £433,015. 11s. 9½d., and the expenditure to £538,501 17s. 7d. The following is the revenue account: Total income received from all sources, £39,831. 0s. 6d. Cost of generation and distribution, rates, taxes, and management, £13,585. 14s. 10d., from which must be deducted interest on mortgages, stock, and bank charges, £14,858. 17s. 7d., and the third instalment set aside out of revenue for the extinction of loan indebtedness amounts to £5,782. 6s. 1d., leaving a surplus for the year, after covering all charges, of £5,604. 2s., to which must be added the surplus at March 25, 1901, £6,294. 6s. 5d., leaving a present available surplus of £11,898. 8s. 5d. The report of Mr. S. Edgar Fedden, general manager and engineer, states that great progress has been made in all departments, and a very large amount of extra work has had to be carried out on account of the change over from 100 to 200 volts pressure, and the change over from 100 to 50 periods per second of alternation of current. He thinks the staff generally are to be congratulated on the successful way in which they have carried out these most difficult operations. In the generating station new plant has been installed as follows: two 550-kw. Electric Construction Company's alternators, coupled to McLaren triple-expansion engines; one 300-kw. Parsons steam-turbine; two Brown's marine type boilers, with Ellis and Eaves's induced draught and Bennis stokers. Five Hotchkiss water-circulators have been fitted to the boilers. A large cooling tower has been erected, capable of dealing with 180,000 gallons of water per hour. The cooling fans and Gwynne pump for lifting the water to the top of the tower are driven by Westinghouse two-phase motors. Two 60in. ventilating fans have been erected in the station to clear the

Digitized by Google

atmosphere and to reduce the temperature, which at times reaches 90deg. F. The litigation with the Brush Electrical Engineering Company with regard to the 600-kw. "Universal" set has been arranged, and terms for the reconstructiou of the plant agreed on. The Ferranti 1,100-kw. set is also being changed over from 100 period single-phase to 50 periods two-phase. There is a very marked improvement in the condition of the electricity mains, which has been brought about by a number of changes. In consequence of these alterations the local extinctions for the 12 months ending March 25, 1902, were only 31, as compared to 206 for the 12 months ending March 25, 1901, and this notwithstanding that many miles of additional mains have been laid and connected, thus greatly increasing the extent of the system. The manufacture of transformers by the Corporation's own factory has proved completely successful, and has been a great boon to the construction department. The supply of transformers in the past was always a source of anxiety. The construction department now finds itself for the first time fully supplied with thoroughly reliable transformers. The work carried out in the meter department has been satisfactory. The work in the factory has been in full swing all the year, and the output considerably increased in order to keep the requirements of other departments supplied. The wiring and fittings department has also made steady progress during the year. The orders of all kinds received during the year numbered 3,592, as against 2,700 during the corresponding period of last year, showing an increase of 892 orders. These orders represent an addition to the supply mains of an equivalent of over 22,000 8-c.p. lamps. During the year experiments have been made with a view to bringing down the initial installation cost to a lower figure, but so far no less expensive system of wiring has been found which justifies a change from that heretofore adopted. It is a pleasure to record that a number of consumers who have had work done by this department during the year have made complimentary communications to the way in which the officials and workmen have carried out their work. These have been passed on to those engaged in the department, who have been much gratified to find their efforts thus appreciated.

HEREFORD ELECTRICITY WORKS.

The report of the Electric Lighting Committee of Hereford for the year ended March 25, 1901, is as follows: Your committee regret that the results for the last financial year are not so satisfactory as during the preceding 12 months. The profits made in the year ending March 25, 1901, were not only sufficient to pay the interest on the capital, but to provide over £700 toward the repayment of capital, leaving only £85 to be borne by the rates. In the present year the surplus revenue, after providing for the interest on the debt, is only £407. 10s. 6d., leaving £392. 9s. 6d. to be provided out of the rates. Your committee told the Council 12 months ago that they could not anticipate to report as favourably in the immediate future as on that occasion, but they had hoped to have had to ask for a smaller sum than that mentioned above, but part of the amount is due to exceptional expenditure, part to the rebate made to customers under the resolution of the committee adopted by the Council reducing the period of maximum demand from two hours to one, and partly to the greater economy of some of the consumers. The quantity of current supplied up to the end of 1901 was in excess of that supplied in 1890 by nearly 30,000 units, but the consumption during the first quarter of this year shows a very slight increase over the consumption for the corresponding quarter of 1901. This is believed to have been caused principally by the remarkably fine bright weather in February. The financial results of the undertaking for the year ended March 25, 1902, are as follows: total units sold, 95,892, as compared with 86.098 units sold in 1900-1. Of these there were charged at 6d. per unit, 66,749 units; at 4d., 20,022; at 3d., 6,851; at 2d., 2,270—producing together, less rebates (£4. 3s. 1d.), £2,102. 16s. 6d. Meter rents amounted to £94. 6s. 5d., and sundry receipts and portion of premium of apprentice to £56. 1s—total, £2,253. 3s. 11d.; less discounts, being the reduction due to the alteration of the period of the maximum demands, £129. 9s. 4d.—total, £2,123. 14s. 7d. The working expenses for the year, including wages, salaries, oil, stores, coal, repairs, taxes, etc., were £1,123. 0s. 7d. and interest £593. 3s. 6d — total, £1,716. 4s. 1d.—leaving a profit towards the repayment of the capital of £407. 10s. 6d.

APPOINTMENTS VACANT.

Clerk of Works, Batley Corporation electricity station, 50s. per week, June 27. See advertisement.

Assistant Engineer, Guardians of St. Mary, Islington, £2 per week. See advertisement.

Shift Engineer, Blackpool Corporation electricity works, £125 per annum, June 23. See advertisement.

Station Superintendent, Blackburn Corporation electricity works, £175 per annum, June 19. See advertisement.

Draughtsmen (several). See advertisements.

Estimating Engineer, with wide experience in permanent-way and overhead equipment for light railways and electric trams. See advertisement.

Assistant Superintendents (5), Indian Telegraph Department, commencing salary 4,200 rupees, June 30. See advertisement.

Teacher of Electric Lighting and Power Transmission, Acton and Chiswick Polytechnic, Bedford Park, W., June 19. See advertisement.

LEGAL INTELLIGENCE.

CLAIM FOR PERSONAL INJURIES.

On the 6th inst. at the West Hartlepool County Court, before Judge O'Connor and a jury, Mary Milne, claimed £100 damages for personal injuries alleged to have been caused by one of the Hartlepools Electric Tramway Company's cars running off the rails at Cleveland-road, Hartlepool, on Feb. 19. The plaintiff alleged negligence on the part of the company or their servants, or, alternatively, the defective condition of the company's lines.

Mr. Shortt, for the plaintiff, stated that on Feb. 19, between 7.30 and 7.45, Mr. and Mrs. Milne and a friend were passengers on one of the company's cars from West Hartlepool to Hartlepool. In Cleveland-road the pavement had been excavated to the depth of about 1ft. on both sides of the line for the purpose of repairs. It was obvious to everyone, said Mr. Shortt, that at such a spot special care was required on the part of the driver; but the car in which plaintiff was travelling did not slacken speed when passing over this portion of the line. The result was that it left the rails, and Mrs. Milne was fiast thrown forward and then backward, striking the base of her spine against the corner of the seat. She was in bed for some six or eight weeks, and the doctor would tell the court that she was by no means recovered yet.

Evidence was given in support of counsel's statement.

Mr. Harrison, for the defence, said the company did not contest their responsibility, and the question for the jury was simply one of assessing reasonable damages.

The jury found for plaintiff for £70, and his Honour gave judgment for that amount with costs.

AN ORGAN MOTOR.

In the Westminster County Court on Friday the Lewisham Electric Installation Company sued the Rev. Tupper Cary to recover the balance of an account due for the supply of an electric motor. Defendant, who was connected with the Oxford (Christ Church) Mission, obtained an estimate from the plaintiffs for a ½-h.p. motor to blow the church organ. The motor was put in, but according to the defendant's evidence was by no means a success. Most wind came up when the organist wanted very little, and *vice versa*. Moreover, the motor made "a frightful noise," which drowned all the music, and it was stated the principal thing heard by the congregation was a series of alarming groans and creaks. But the worst complaint was that the dynamo fired during a service, and Mr. Cary described the effect as resembling a big catherine wheel, which flung sparks in all directions and frightened the organist almost out of his life. That happened last year, and they had been afraid to use it since. Plaintiffs sued for £30, balance of £60, and the defendant counterclaimed for the return of the £30 paid, and £10, the cost of removing the useless motor.

Judgment was eventually given for the defendant on the claim, and on the counterclaim for £35, with costs.

EFFECT OF TRAMWAY COMPETITION.

At the Leeds Bankruptcy Court last week the affairs of E. Spurden, an omnibus proprietor, of Leeds, were enquired into. It appeared that the debtor's failure was due to the advent of the electric tramcars into the city. He explained to the judge that people would not ride in his 'buses once the electric cars were introduced on Cardigan-road, though he had thought he should always be able to run omnibuses on certain routes. But now nobody wanted 'buses anywhere. Vehicles which had cost him £145 had sold for £4. 10s. and £7.

Mr. Waugh asked for the bankrupt's discharge, which the official receiver opposed.

His Honour remarked that the practice of municipal corporations entering into competition with individual traders, while it was perfectly justifiable, entailed a great deal of personal hardship. And while the trader who was brought to bankruptcy by reason of such competition had no legal claim for compensation, he thought in a case of that sort every consideration should be shown to the debtor. The debtor, however, had failed to keep books, and on that account he must, under the Act, suspend the discharge for two years.

CONSULTING ENGINEERS' FEES.

On Tuesday in the Ormskirk County Court, before Deputy-Judge Goldthorpe and a jury, Messrs. J. and J. S. Enright, consulting engineers, of London, sued the Ormskirk Urban District Council to recover 10 guineas for the preparation of a preliminary report on the electric lighting of the town. It appeared that on Oct. 22 last year the Council's surveyor wrote the plaintiffs to the effect that his Council were contemplating laying down an electrical plant to light some of the streets of the town, and stating that "the Electric Lighting Committee should esteem it a very great favour if they could see their way to supply him with as much information as they possibly could relative to the question of cost for the supply of the public and private lighting of the town by electricity." Upon this letter Mr. J. S. Enright prepared a preliminary report. Certain details were entered into as to the probable demand and income and expenditure, but the whole was summed up in fixing the probable cost of an installation at £7,000, while the income would probably leave a profit of £280, after allowing for interest on loan, sinking fund, etc. Afterwards the plaintiffs sent in an account for 10 guineas for the report, which was repudiated, hence the present action. The defence set up was that the District Council's surveyor was never authorised to ask

Digitized by Google

for the report in question, without first counting the cost, and liability or the sum claimed was denied.

Eventually the jury returned a verdict for the defendants, and judgment was accordingly entered in their favour.

His Honour, however, directed that each party should pay their own costs.

COMPANIES' MEETINGS AND REPORTS.

ANGLO-PORTUGUESE TELEPHONE.

The ordinary meeting of this Company was held at the offices, New Union-street, Moorfields, London, Mr. H. Fielden Jackson presiding.

The **Chairman**, in moving the adoption of the report and accounts, said the past year had been one of continued prosperity. They had added 70 new subscribers, who now numbered 2,534. The revenue was £20,619, being an increase of £1,410 on that of the previous year, while their expenses had decreased by £280. The contract with the electric tramway company of Lisbon had been completed, and £6,000 compensation had been paid by that company. This amount it was proposed to carry to the reserve fund, bringing that fund up to £38,000.

The motion was adopted unanimously.

ELECTROLYTIC ALKALI.

An extraordinary general meeting of this Company was held on Saturday at Middlewich for the purpose of increasing the number of directors to nine. Mr. W. Thomson presided.

The meeting unanimously agreed to the increase, and Mr. Geo. Herbert Harrison and Major Wm. Lee Pilkington were chosen as the additional directors.

The **Chairman** observed that there was no other business before the meeting, but he thought it well to state that the applications for shares had been successful. About £120,000 was applied for, and they only needed £100,000. As a matter of fact they had allotted 50,000 preference and 48,852 ordinary shares, and that he thought might be regarded as a highly satisfactory result.

The meeting terminated with a vote of thanks to the chairman and his co-directors.

MEXICO ELECTRIC TRAMWAYS.

The ordinary general meeting of the shareholders in the above Company was held on Wednesday at Winchester House, Colonel Sir Charles Euan-Smith presiding.

The **Chairman**, in moving the adoption of the report, said the year under review had been one of somewhat abnormal depression, which, while directly affecting their sources of revenue, had also seriously increased the sum of their outgoings. It was, therefore, to the future that he would call their special attention, believing, as the directors did, that they had now passed through the more costly period of their existence as an enterprise, and that brighter times were in store for them. It could never have been anticipated that while the whole of this large system was in actual process of reconstruction their returns would have been of a very satisfactory character; but the disadvantages that they could foresee were immensely emphasised and increased by those that could not be foreseen; such, for instance, as the breaking-up of the city roads for the sewerage construction works, which materially interfered with the business. The outlook, however, was now of a most encouraging nature, and in proof of this he quoted the cable returns received two days ago from Mexico, which showed that the receipts for the last month were 10,000dol. better than those of the preceding month, and no less than 18,000dol. increase over the returns of the same month last year. The construction of the whole line was now nearing completion, and when once all the important lines were worked by electricity they might have good reason to anticipate that they should be on the high road to success.

Mr. Ludwig Breitmeyer seconded the motion, which was unanimously adopted.

The retiring directors, Mr. Ludwig Breitmeyer and Dr. Rutherford Harris, having been re-elected,

A vote of thanks to the chairman brought the proceedings to a close.

W. T. HENLEY'S TELEGRAPH WORKS.

Report of the directors, to be presented to the shareholders at the ordinary general meeting to be held at the Cannon-street Hotel on Friday, June 20, 1902, at 12 o'clock:

The negotiations for the amalgamation of the Company with Messrs. Callenders' Cable and Construction Company, Limited, are still proceeding, and the directors are therefore unable to submit the terms to the shareholders, as intimated in their circular of Feb. 21 last. The directors are of opinion, however, that the payment of the final dividend should not be longer deferred, they therefore now submit the annual report, and will communicate the terms of the amalgamation to the shareholders as soon as the negotiations are completed. The accounts show that during the past year a net profit has been made of £64,447. 19s. 9d. After payment of directors' and auditors' fees, debenture interest, and income tax, and making the usual allowance for depreciation of buildings, plant, machinery, etc., there remains £57,449. 13s. 3d., making, with £24,210. 16s. brought forward from last year, a total of £81,660. 9s. 3d. The directors have transferred £1,000 to the debenture redemption sinking fund and £11,000 to the reserve account, and they recommend the payment of a dividend on the ordinary shares at the rate of 20 per cent. per annum (less income tax), including the interim dividends of 5 per cent. paid on Sept. 1, 1901, and 10 per cent. paid on March 1 last. These payments will, together with the preference dividend for the year, amount to £54,875, leaving £26,785. 9s. 3d. to be carried forward. The dividend warrants will be posted on June 20, 1902. Mr. Sydney Gedge and Mr. Frederick Newton retire by rotation in accordance with the provisions of the articles of association, and, being eligible, offer themselves for re-election. The auditors, Messrs. Ball, Baker, Deed, Cornish, and Co., retire, and, being eligible, offer themselves for re-election.

CHADBURN'S (SHIP) TELEGRAPH.

The report of the directors for the year ended March 31 last states that the balance at the credit of the profit and loss account is £11,577. Less managing director's remuneration, directors' fees, and expenses, depreciation on properties and plant, however, £2,811, there is £8,765. From this amount £5,400 must be deducted, being dividends which have been paid at the rate of £6 per cent. per annum on the preference shares and an interim dividend at the rate of £6 per cent. per annum on the ordinary stock, leaving £3,365 to deal with. The directors propose to pay a dividend on the ordinary shares of £10 per cent. per annum for the half-year ended March, making with the interim dividend already paid a dividend of £8 per cent. per annum for the 12 months, carrying forward £365, which, together with last year's balance—namely, £3,929—makes a total carried forward of £4,294.

BRITISH ELECTRIC TRACTION.

Directors: Sir Charles Rivers Wilson, G.C.M.G., C.B. (chairman); Charles Sinclair Drummond; the Hon. Sir Charles William Fremantle, K.C.B.; Emile Garcke, M.I.E.E.; C. Shirreff B. Hilton; the Right Hon. Lord Rathmore; John Smith Raworth, M.I.C.E. Managing director: Emile Garcke, M.I.E.E. Technical director: John S. Raworth, M.I.C.E. Chief engineer: Stephen Sellon, A.M.I.C.E. Secretary: Charles H. Dade.

Report of the directors to be presented to the shareholders at the sixth ordinary general meeting of the Company, to be held at Hamilton House, Victoria-embankment, E.C., on 16th inst. at 12 noon:

The profits, including £21,457. 5s. 7d. brought forward from last year, amount to £224,727. 5s. 5d. This does not take into account the premiums, amounting to £121,184. 11s. 6d., received in respect of new share and debenture capital, and which have been carried direct to reserve. After deducting the proportion of general expenses chargeable to revenue, and also the expenses incurred in connection with schemes not proceeded with and written off, sundry reserves, contributions to superannuation fund, and interest on debenture stock, there remains a net profit of £158,307. 7s. 8d. which the directors propose should be applied as follows: reduction of goodwill account, £1,500; reduction of licenses and testing of new systems account, £2,500; reduction of furniture account, £510. 14s.; dividend at the rate of 6 per cent. per annum on the preference shares for the year ended March 31, 1902, including the dividend paid to Feb. 15, 1902, and proportion of dividend payable Aug. 15, 1902, accrued to date, £54,847. 4s. 9d.; dividend at the rate of 12 per cent. per annum on the ordinary shares for the half-year ended March 31, 1902, making with the interim dividend at the rate of 6 per cent. per annum, paid for the half-year ended Sept. 30, 1901, a total distribution of 9 per cent. for the year, £71,511. 1s. 11d.; carried forward to next account, £27,438. 7s. The directors further propose that each shareholder should receive out of the issue of 20,000 ordinary shares referred to below an allotment at par of one ordinary share in respect of every 10 shares, whether ordinary or preference, held on June 6, 1902. The option given to Messrs. J. S. Morgan and Co. and the Electric and General Investment Company, Limited, to call for allotment of the unissued balance of 37,926 ordinary shares and 10,000 preference shares was exercised on July 8, 1901, and the shares have been duly allotted and paid for in full. There has also been issued £210,906 5 per cent. perpetual debenture stock. The total premiums received in respect of these issues, after deducting the expenses, amount to £121,184. 11s. 6d., and the whole of this amount has been added to reserve, which now stands at £459,705. 4s. 10d. The subscribed share and debenture capital at March 31 was £1,000,000 in ordinary shares of £10 each, £1,000,000 in 6 per cent. cumulative preference shares of £10 each, £810,906 in 5 per cent. perpetual debenture stock — total, £2,810,906. The directors recommend that the nominal capital of the Company be increased by the creation of 100,000 ordinary shares of £10 each and 100,000 preference shares of £10 each. A part of this new capital is required to carry out the absorption of the Electrical Power Distribution Company by an exchange of shares referred to below. It is proposed to make an immediate issue of 20,000 ordinary shares by allotment to the shareholders, as stated above. The directors consider it undesirable to make any public issue of ordinary shares at the present time, as in their opinion the market price of the shares is below what they consider to be their value. The balance under the head of contracts and undertakings, after deducting the cost of undertakings transferred, and after writing off expenses incurred in respect of schemes not proceeded with, but including a proportion of general expenses, is £199,179. 2s. 5d., made up as follows: expenditure on works and undertakings for account of other companies, £26,725. 0s. 1d.; expenditure on works and undertakings owned or leased by the B.E.T. Company and for general stores, £99,988. 5s. 6d.; expenditure in connection with schemes in course of development, and on Acts of Parliament, provisional orders, light railway orders, and other rights and powers secured or in course of promotion, less reserved, £72,465. 16s. 10d. The total amount of investments, after deducting cost of securities sold, stands at £2,332,932. 17s. 9d., and is made up as follows: consols (cost), £161,757. 19s. 8d.; loans and advances to associated companies and

Digitized by Google

others, and deposits, £144,875. 16s. 1d.; mortgages, debentures and debenture stock, and shares of associated and other companies, less reserved, £2,026,299. 2s. There are certain contingent liabilities in respect of some of these investments. A portion of the consols is deposited with the Paymaster-General in respect of Acts of Parliament, etc. The Company has a large holding in the Electrical Power Distribution Company, and the two companies have joint interests in several combined electric lighting, power, and traction undertakings. Your directors are of opinion that the efficiency of the combined organisations will be increased, and that economies can be effected, by the complete absorption by the Company of the Electrical Power Distribution Company. With this view the directors propose to offer to the other holders of shares in the E.P.D. Company one B.E.T. fully-paid ordinary share for each fully-paid ordinary share in the E.P.D. Company and one B.E.T. fully-paid preference share for each E.P.D. Company fully-paid preference share. There are also 200 deferred shares of £1 each in the Electrical Power Distribution Company, which were issued and paid for in cash at the time of the formation of the Company. They are held by Messrs. E. Garcke, J. S. Raworth, W. L. Magden, R. Percy Sellon, and G. Offor. In 1900 an agreement was made between the E.P.D. Company and the holders of these shares, by which the E.P.D. Company has the option exercisable at any time within 10 years from Jan. 1, 1900, to extinguish the special rights attaching to such shares on the basis of the payment of £10,000 in cash. An agreement has now been made between the B.E.T. Company and the holders of the deferred shares, giving the B.E.T. Company the option within 12 months from June 6, 1902, of purchasing the 200 deferred shares at the price of £10,000, payable in cash, or at the option of the B.E.T. Company in fully-paid ordinary shares of the B.E.T. Company at the market price of the day on which the option is exercised, and upon the condition that the B.E.T. Company shall exercise such option in the event of its acquiring a majority of the ordinary and preference shares of the P.E.D. Company within the period aforesaid. It is intended to offer Mr. Madgen, the managing director of the E.P.D. Company, a seat on the Board. The British electrical superannuation fund is now in full and satisfactory operation. At the end of 1901 the membership was 81, and that 29 associated companies and undertakings had signified their intention to contribute to the fund on behalf of their salaried staff. The sum of £452. 2s. 3d. has been contributed by the Company during the past year. Attention is called to the British Electrical Friendly Society, which was constituted in December last, since when 19 branches have been formed in various parts of the country and 1,255 men in the service of the British Electric Traction Associated Companies have joined the society. The directors who retire this year are Mr. C. Shirreff B. Hilton and the Hon. Sir Charles W. Fremantle, K.C.B., and both are eligible for re-election. Messrs. Fred W. Smith and Co. retire, and offer themselves for re-election.

BALANCE-SHEET.

PERTH ELECTRIC TRAMWAYS.

The report of the directors for the 18 months ended Dec 31, 1901, states that during the period 7 miles have been in operation for 3 months, 10¼ miles for 3¾ months, and 13 miles for 11¼ months, being an average of about 11½ miles during the 18 months. The total gross revenue earned from this mileage during that period amounted to £60,268. During the 18 months £102,109 has been spent on the construction of further sections, extra motive power, and additional cars. Since the date of the accounts additional routes have been completed, making the total mileage now in operation 16¼ miles. The working of the tramways has proceeded without interruption, and the service instituted by the management in Perth has given every satisfaction to the public. The accounts show a net profit from working of £21,697, from which has to be deducted interest on debenture stock and loans, leaving a net balance of £7,354. From this it is proposed to pay interest on the cumulative preference shares to June 30 last, which will absorb £3,272 and leave a balance of £4,081. After allowing for the debit of £2,957 brought forward from last account, a credit balance of £1,124 remains and is carried forward. The traffic receipts since Dec. 31 have been most satisfactory, and whereas in the year 1901 the weekly takings only exceeded the sum of £1,000 in a few instances, the weekly traffics in 1902 have not in one single instance been less than £1,000.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Nuneaton.—The Urban District Council invite tenders for a water-tube boiler and pipework. Tenders by 18th inst.

Shanghai.—The last day for receiving tenders for the proposed municipal tramway and motor 'bus service is June 30.

Blackpool.—The Corporation invite tenders for the supply and delivery of carbons for year ending March 31, 1903. See advertisement.

Sunderland.—The Corporation invite tenders for the supply of permanent way, overhead equipment, and cables. Tenders by July 9. See advertisement.

West Ham.—The Council invite tenders for 50 double-deck electric tramcars, complete with electrical equipment. Tenders by July 8. See advertisement.

Manchester.—The Tramways Committee invite tenders for the supply of line materials, trolley wire, etc., for overhead equipment. Tenders by June 14. See advertisement.

Bristol.—The Electrical Committee invite tenders for feed and general service pumps, water-softener, and tank coke filters and pipework. Tenders by June 20. See advertisement.

Romford.—The Urban District Council invite tenders for the construction and maintenance of electricity supply works in the district. Tenders by June 30. See advertisement.

Digitized by Google

Valparaiso.—The Municipality are inviting tenders for electric lighting and tramways. We understand that particulars may be obtained from the Chilian Consul. Tenders by Sept. 1.

Bury.—The Tramways Committee invite tenders for the supply and delivery of rails and fishplates, fishbolts and nuts, tiebars, points and crossings, and sole or anchor plates. Tenders by June 24.

Walsall.—The Corporation invite tenders for the supply and erection of a reversible booster and switches, to work in series with a battery on a tramway circuit. Tenders by June 27. See advertisement.

Birkdale (Lancs.).—The Urban District Council invite tenders for wiring of the town hall and fire station. Specification, etc., may be obtained on application to Mr. J. F. Keeley, accountant, Town Hall, Birkdale Tenders by 14th inst.

Bootle (Lancs.).—The School Board invite tenders for the installation of electric light in the Bedford-road School, Bootle. Specification, etc., may be obtained from Mr. F. K. Wilson, clerk, School Board Offices, Bootle. Tenders by June 20.

Lowestoft.—The Corporation invite tenders for the construction of tramways, rails, fishplates, and bolts, and permanent-way construction. Specification, etc., may be obtained from Mr. R. Beattie Nicholson, town clerk, Lowestoft. Tenders by July 12.

Warrington.—The Corporation invite tenders for the following: (Section 11) tramcars, with motors and electrical equipment complete. Specification, etc., may be obtained at the offices of Messrs. Preece and Cardew, 8, Queen Anne's-gate, Westminster, S.W. Tenders by June 18.

Launceston (Tasmania).—The Corporation invite tenders for polyphase generating, transmitting, and distributing plant and apparatus, transforming apparatus, reconstruction of existing plant, and enclosed arc lamps and accessories. Tenders by Sept. 15. See advertisement.

Salford.—The Tramways Committee invite tenders for the supply of about 2,000 tons of tramrails, together with fishplates, soleplates, and tiebars. Further particulars may be obtained on application to the General Manager, Tramways Department, Town Hall, Salford. Tenders by June 17.

Kirkcaldy.—The Corporation invite tenders for wiring the central station. Specification, etc., can be obtained from Mr. Wm. L. Macindoe, town clerk, or seen at (but not obtained from) the office of Messrs. Kennedy and Jenkin, 17, Victoria-street, Westminster, S.W. Tenders by 21st inst.

Manchester.—The Tramways Committee invite tenders for: (a) chilled cast-iron car wheels and axles; (b) lamp glasses for cars. Specifications may be obtained from Mr. J. M. McElroy, general manager tramways department, 55, Piccadilly, Manchester. Tenders by 1 p.m. on 14th inst.

Stretford.—The District Council invite tenders for the following in connection with its scheme for supply of electrical energy: Steam-raising plant, comprising boilers, superheaters, economisers, etc; generators, comprising engines, dynamos, condensers, pumps, etc.; and mains. Tenders by June 18. See advertisement.

Astrachan.—Erection of electric generating station and installation of public and private lighting, commencing with 150 arc and 6,000 incandescent lamps. Manufacturers who will undertake to finish the work within two years can obtain particulars from the Municipality. Agents will not be able to tender. Tenders by June 7-20.

Ipswich.—The Corporation invite tenders for the supply, delivery, and erection at the generating station, Constantine-road, Ipswich, of engines and dynamos, storage battery, overhead hand travelling crane, feeders, mains, and road work, permanent-way construction of tramways, and arc lamps. Tenders by July 5. See advertisement.

Little Woolton.—The Urban District Council invite tenders for (1) supply, laying, and jointing of cables and the supply and fixing of junction boxes and lamp connections: and (2) supply of lamp fittings. Specification, etc., may be obtained from the surveyor, Mr. Richard Simmons, Grange-lane, Gateacre, near Liverpool. Tenders by 20th inst.

Stockton-on-Tees.—The Corporation invite tenders for the supply, delivery, and erection of one 300-kw. steam generator, two Lancashire type boilers, one switchboard panel and instruments, surface condenser and cooling plant, pipework and valves, extension feeders, and mechanical stokers, economiser, and feed pump. Tenders by June 17. See advertisement.

Rotherham.—The Corporation invite tenders as follows: (Specification No. 12) tramway and lighting feeders, mains, and other cables, with roadwork; (13) boilers—first extension, consisting of three Lancashire boilers, with mountings, erected complete; (14) additional steam dynamo, with normal output of 320 kw., erected complete. Tenders by June 17.

Bury.—The Tramways Committee invite tenders for the work required in the construction of the permanent way in several parts of the borough—viz.: Fairfield section, Bolton-road section, Heywood-street and Knowsley-street sections. Specifications, etc., can be obtained on application at the office of Mr. Arthur W. Bradley, borough engineer and surveyor. Tenders by June 24.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramways and Electricity Board invite tenders for the supply, delivery, erection, and construction of three 500-kw. steam-driven, direct-coupled three-phase alternators, etc.; three 50-kw. steam-driven, direct-coupled continuous-current exciters, etc.; and permanent way, including copper bonding and conduits for cables. Tenders by July 7. See advertisement.

Wigan.—Tenders are invited for the wiring and equipment for electrical lighting of new warehouse, bakery, and stables, etc., in Dorning-street, Wigan. Specifications, etc., to be obtained and plans inspected at the offices of Messrs. J. B. and W. Thornley, architects, College-chambers, Library-street, Wigan. Tenders by 12 noon on 16th inst., addressed Wigan and District Equitable Co-operative Society, Limited, Powell-street, Wigan.

Worthing.—The Corporation invite tenders for the erection of a circular brick chimney shaft for their electric generating station, High-street, Worthing, 140ft. high from the ground level and 7ft. 6in. inside diameter at the top (the Corporation will construct the foundations and other brickwork to the ground level). Full particulars can be obtained on application to the Borough Surveyor, Municipal Offices, Liverpool-road, Worthing. Tenders by June 16.

Rotherham.—The Corporation invite tenders for the following materials: 2 pairs of cable jacks; 1 hand cart; 1 watchman's box; 200 yards of fencing chain with spikes; 1 tar boiler; 1 portable Weston voltmeter, with case, ranging from 0 to 300 and 0 to 600 volts; set of 6 Crosby indicators complete, with accessories and case; set of stocks and dies; 300 yards of ·1 – ·05 – ·1 triple-concentric Callender's vulcanised-bitumen sheathed cable; 250 yards of ·035 concentric cable, as above; 500 yards of ·022 ditto; 500 yards of ·012 ditto; 50 service boxes; 50 fuse boxes; 10 tons of bitumen. Tenders by 14th inst.

Genoa.—The Board of Trade have received through the Foreign Office a dispatch from H.M. Consul-General at Genoa notifying that tenders will be received up to 11 a.m. on 20th inst. for the supply of electric lanterns and lamps for use on board Italian warships to the estimated total value of 39,823 lire (about £1,555), to be delivered at the Royal Arsenals of Spezia, Naples, Venice, and Taranto. Tenders will be opened simultaneously at the General Directorates of the Royal Arsenals above mentioned, a deposit of 3,980 lire (about £155) being required to qualify any tender. A copy of specification, together with a translation thereof, may be seen on application at the Commercial Intelligence Branch of the Board of Trade, 50, Parliament-street, S.W., any day between 10 a.m. and 5 p.m.

Shanghai.—Messrs. Preece and Cardew are authorised to receive tenders for the supply f.o.b. of the following plant: one 100-kw. high-speed engine and alternator and exciter, for the Shanghai Municipal Commissioners. The engine is to be of the enclosed double-acting type, steam pressure 130lb.; and the alternator of the stationary armature type, 2,100 volts, 100 periods. As the plant is urgently required, offers of suitable second-hand plant will be considered. Specification, with general conditions and form of tender, may be obtained from Messrs. Preece and Cardew, 8, Queen Anne's-gate, Westminster, on payment of £1. 1s., which will be returned on receipt of a bona fide tender. Sealed tenders, endorsed "Shanghai Steam Alternator," must be delivered to Messrs. Preece and Cardew by noon on 17th inst.

RESULTS OF TENDERS.

Soulcoates.—The Guardians have accepted the tender of the Hart Accumulator Company to supply accumulators for the workhouse, at £581. 8s.

Burton.—The Town Council have accepted the tender of the British Thomson-Houston Company, of Rugby, for generators and switchboard for the tramway system, at £4,099.

Blackburn.—The tender of Dick, Kerr, and Co., Preston, for the supply of dynamos, with engines by Willan and Robinson, Rugby, at £18,127, has been accepted.

Cleckheaton.—The Urban District Council have accepted the tender of the Lancashire Dynamo and Motor Company, Cleckheaton, for the supply, delivery, and erection of continuous-current electric motors.

Carnforth.—The Hematite Iron Company have decided to instal one of Willans and Robinson's standard compound engines for direct coupling to a dynamo of Mather and Platt's make for supplying power to their works.

Mersey Railway.—The Forest City Electric Company, Manchester, have received the contract from the British Westinghouse Electric and Manufacturing Company for the copper bonds and hydraulic bonding tools for the Mersey Railway.

Broughty Ferry.—The Town Council have accepted the tenders of Callender's Cable and Construction Company for cables at £4,964, and for a middle-wire distributor at £566; also that of Thomson, Son, and Co., Limited, Dundee, for steam-pipes and auxiliary gear.

Liverpool.—The tender of Willans and Robinson, Rugby, has been accepted for three 1,500-h.p. engines for direct coupling to Siemens dynamos. They have also received an order for three 1,500-h.p. engines from the British Thomson-Houston Company for direct coupling to three-phase alternators.

Grimsby.—The Town Council have accepted the following tenders: Gilbert Arc Lamp Company, Specification No. 15, arc lamps, £141. 11s 6d.; Mackenzie Bros., No. 16, arc lamp posts, £176. 15s.; Doulton and Co., No. 17, stoneware pipes, £54. 19s.; Johnson and Phillips, No. 18, cables, £229. 4s. 4d.

South Wales.—The South Wales Electrical Power Distribution Company have accepted the tender of Willans and Robinson, Rugby, for three engines of 3,000 h.p. each, and for several of smaller size, for their Pontypridd station. These engines will be direct coupled to alternators for supplying current for general power distribution purposes.

London County Council.—The Council have received the following tenders for electric wiring and fittings for the fire station in Euston-road: D. Assersohn, £268. 10s. (accepted); Lawrence and Co., £323; Jackson Bros., £352. 3s. 6d.; W. Mossop and Co., £357; C. Cooper and Co., £375. 10s.; A. Goldsmith and Co., £400; Wakelin and Co., £597. Tenders for a water-bore for feeding the boilers of the electricity generating station to be erected at Greenwich have been received

Digitized by Google

from four firms, and, assuming that the boring would be 300ft. deep, these prices, which would be less should suitable water be found at a higher level, work out as follows: Le Grand and Sutcliffe, £310 for 8½in. borehole (accepted); Merryweather and Sons, £395 for 9in. borehole; C. Isler and Co., £545 for 10in. borehole; Docwra and Co, £592 for 9in. borehole. This includes boring, erection and removal of the boring plant, and the use of trial pumps for the purpose of ascertaining the quantity of water available.

Fulham.—The Guardians have received the following tenders for the supply, delivery, and erection on their premises of pipework:

Aiton and Co.	£1,330	13	0
Babcock and Wilcox, Limited	1,413	3	0
Sir Hiram Maxim Electrical and Engineering Company, Limited	1,439	4	0
D. Stewart and Co., Limited	1,541	10	0
Sir Hiram Maxim Electrical and Engineering Company, Limited	1,589	4	0
Rosser and Russell, Limited	1,643	4	0

Hackney.—The Borough Council have received the following tenders:

Boilers.

Stirling Boiler Company	£6,653	0	0
Babcock and Wilcox (accepted)	6,910	5	0
Hughes and Stirling	6,954	0	0
W. R. Renshaw and Co.	6,995	0	0
J. Thompson	7,385	0	0
R. Hornsby and Sons	7,620	0	0
E. Danks and Co., Oldbury	9,594	0	0

Water-softening plant.

Babcock and Wilcox (accepted)	1,120	0	0
Baker's Patent Appliances Company	1,206	0	0
J. Barrett	1,070	0	0
Desrumaux's Automatic Water Softener and Purifier	1,489	10	0
Doulton and Co.	1,696	0	0
Glasgow Patents Company	1,043	0	0
Lesson and Hjort	1,300	0	0
Masson, Scott, and Co.	1,540	0	0
Mather and Platt	1,795	0	0
Porter-Clark Water Softening Company	2,201	0	0
Potter and Co.	1,725	0	0
Sir Hiram Maxim Electric and Engineering Company	2,140	0	0
Stanhope Water Engineering Company	1,626	0	0
J. Thompson	2,485	0	0
J. Wright and Co.	2,442	0	0

Wiring offices for electric lighting.

National Electric Wiring Company (accepted)	130	15	9
J. C. Christie	164	1	8
Foote and Milne	165	4	8
J. H. Golding	184	13	3
Tamplin and Makovski	219	12	6

BUSINESS NOTES.

NOTICE.—On Wednesday morning we received a label and piece of string addressed to us. The postmark on the same is Preston, and the date June 10. The label is marked "Found without contents" by the Post Office officials, and we shall be obliged if the sender will notify us as to the nature of the parcel posted.

TRACTION.

Dunston.—Lieut.-Colonel von Donop has made his official inspection of the tramway at this place.

Aspull.—Inspection of the Whelley tramway extension has been made by the Board of Trade officials.

Leeds.—It is expected that the Street-lane tramway route will be ready for opening between the 17th and 20th inst.

Macclesfield.—It is proposed to include Bollington, Langley, and other districts in the light railways scheme for the district.

Northfleet.—The District Council have sealed the deed regulating the laying of the electric tramway cables under the footpaths.

Torquay.—A deputation are to be sent to Wolverhampton to inspect the Loraine system of electric traction in operation there.

Doncaster.—The takings on the day of the opening of the new tramways amounted to £43. 19s. 5d., representing 10,553 persons.

Halifax.—The working of the Corporation tramways last year cost £55,094, which, it is reported, exceeded the receipts by the sum of £27.

Reddish.—Colonel von Donop, Board of Trade inspector, on Friday inspected the Reddish section of the Stockport electric tramways.

Warrington.—Messrs. Bennie and Thompson have been requested to proceed with the construction of the tramway to Manchester-road forthwith.

Southend.—The subject of the Corporation's proposed light railway from Southend to Shoeburyness has been referred to the Highways Committee.

Singapore.—We learn that the Straits Legislative Council have unanimously passed the Bill for the introduction of electric tramways in Singapore.

Hammersmith.—The Borough Council have now approved the proposals contained in the London United Tramway Company's Bill for extending their lines in the borough.

Clydebank.—It is anticipated that in consequence of the arrangement come to with Glasgow, noted last week, the electric cars will be running to Dalmuir in three months' time.

Brighton.—The engineer has been instructed to arrange for Mr. Spencer's appliance for preventing the run-back of cars on a gradient to be fixed to the cars at a total cost of £5. 15s. each car.

Torry.—The Tramways Committee at their last meeting had a discussion on the question of a tramway in Torry, and the committee agreed to consider as to the promotion of a Bill on the subject.

Paris.—An electric railway between Paris and Versailles was opened to the public on Saturday. It has been built by the Western of France Company. There will be 15 trains per day in each direction.

Ainsdale.—A deputation from the Parish Council will shortly wait upon the Tramways Committee of the Birkdale Urban District Council with regard to extending the tramway system, when completed, into Ainsdale.

Hampton.—The London United Tramways Company have accepted the Council's requirements as to the double line opposite Ivy House, Hampton Court, and the laying of the 18in. margins with granite setts.

Rochdale.—The date on which the Norden section of the new tramways will be opened to the public depends upon the Board of Trade inspection. Probably in less than a fortnight the cars will be running on this section.

Nottingham.—The tramway along Lenton-boulevard to the Canal-street junction is being proceeded with in earnest, and with some degree of certainty it may be anticipated that cars will be running on this route in three months.

Dewsbury.—Terms have been agreed upon between the Corporation and the British Electric Traction Company for the supply to the company by the Corporation of energy for the electric tramways which are now being constructed.

Blackburn.—During the week ending May 30 the passengers carried numbered 145,558, and the receipts amounted to £841. 5s. 1d., compared with 179,794 passengers and £846. 5s. 7d. receipts—a decrease of 34,236 passengers and £5. 0s. 6d. receipts.

Military Motors.—The Kaiser has consented to the introduction of the Thornycroft steam-wagon into the German army. The wagon will carry 3½ tons on an ordinary macadam road, and will haul a further 3½ tons at a speed of six miles per hour.

Bury.—The Board of Guardians have appointed a deputation to wait upon the Tramway Committee of the Bury Corporation, urging them to extend their tramway system in the Bury Old-road to the Bury boundary, or at least to the Bury Workhouse.

Swansea.—The Swansea tramway service has been augmented by the docks cars running all the way to the Slip. On each of the three sections using St. Helen's-road there will be additional cars, ensuring a car leaving the hospital for town every 2½ minutes.

Audley.—Another unsuccessful effort has been made to secure for the Audley district a much-needed tramway loop line, the Tramways Committee having decided that they cannot at present see their way to depart from their previous resolution not to proceed with the extension.

Light Railways.—The Board of Trade have confirmed orders authorising the construction of light railways in the borough of Swansea and in the rural district of Llangyfelach, in the county of Glamorgan, and amending the Grimsby and Saltfleetby Light Railway Order, 1898.

Batley.—The contractor for the permanent way of the new tramway has now commenced operations. With regard to the proposed agreement between the Corporation and the British Electric Traction Company, it is likely that by the next Council meeting the agreement will have been completed.

Newcastle.—Notice has been given that the *locus standi* of the Tyneside Tramways and Tramroads Company, who have petitioned against the Newcastle Corporation Tramways Bill, is objected to. It will now be left for the Court of Referees to decide between the petitioners and the promoters.

Christchurch (N.Z.).—The Christchurch boroughs interested in forming a tramway board have agreed on the main details of a Bill to constitute the Board. Each local body is to have the nomination of three members. The Board will have control of the expenditure of £250,000 under the proposed scheme.

Blackpool.—A proposal for 1d. stages on the tramcars on the promenade has been rejected by the Town Council. The work in connection with the new road tramway is now practically completed. Only the squaring up of the track remains to be done, and this work will be carried out by the permanent staff.

Merthyr.—In connection with the tramway scheme at this place the Merthyr District Traction Company have notified the Urban District Council that they cannot increase their offer of £400 towards the cost of making a new bridge over the River Taff at Cefn, and pointing out that even this offer cannot be kept open indefinitely.

Glasgow.—An extraordinary meeting of the shareholders of the Glasgow Tramway and Omnibus Company has confirmed resolutions relative to the voluntary winding-up of the company. The salaries of Mr. Wm. Clark, chief engineer of the tramways, and of Mr. M. B. Field, the electrical engineer, have been advanced to £600 and £500 respectively.

Cardiff.—Major Druitt, of the Board of Trade, has inspected the remaining portions of the Corporation electric tramways—viz., the Cathays section, the docks section, from the Hayes to the pierhead, and that part of the Canton section between the workhouse and St. Mary-street as far as Wood-street corner. Yesterday all the sections were formally opened.

Digitized by Google

Northumberland.—We understand that in consequence of the opposition to the Tyneside Tramways and Tramroads Bill and the Northumberland Electric Tramways Bill having been withdrawn, these Bills have been removed from the group of opposed Bills in which they were placed. They have now been referred to the chairman of the Committee of Ways and Means.

Reigate.—The promoters of the electric railway which it is proposed to run from the City to Reigate and Redhill are taking steps to bring their scheme into definite shape. The London terminus would be at the Monument, and the route to be followed would be *via* Brixton, Streatham, Norbury, Croydon, Warlingham, and Caterham, with a branch from Warlingham to Westerham.

Plymouth.—The Tramway Committee are making arrangements for running the electric cars over the lines in Union-street as far as the boundary of the borough. The construction of the Beaumont-road section of the Corporation tramways has cost £11,303. This is £773 more than the sum sanctioned by the Board of Trade, and it is proposed to make application to borrow the extra £773.

Walsall.—The Tramway Committee report having authorised the town clerk to take such steps as may be necessary to defend an action brought by the South Staffordshire Tramway Company to recover rent in respect of the tramway undertaking within the borough. The action, it is explained, is against the lessee company, which at present works the tramways, but the Corporation have agreed to defend it.

Barrow.—The negotiations between Barrow Town Council, the Furness Railway Company, and British Electric Traction Company with respect to the latter company taking over the tramway system, and substituting electricity for steam, have now been concluded. The present condition of engines and cars has long been a matter of serious complaint, and two months ago the Council refused to license them any longer.

Birkenhead.—The new offices of the tramways manager and staff are to be erected at the Laird-street depôt. The attention of the Tramways Committee is to be called to the question of providing facilities for the travelling public in the earlier parts of Sunday, bearing in mind the fact that between nine and ten o'clock on Sunday mornings the Liverpool authorities offer almost as good facilities as on weekdays.

Parkstone.—The Board of Trade held an enquiry on Monday relative to the application of the Poole and District Electric Traction Company to extend their tramlines through Parkstone. The opposition of the railway company to the proposal was first heard, and ultimately the Board of Trade officials decided in favour of the tram company. The opposition of the frontagers along the proposed line of route remains to be dealt with.

Tramway Competition.—It is reported in the provincial Press that several leading railway companies owning large systems in the Midlands and North of England are seriously considering the advisability of lowering their passenger fares in all three classes, with a view to competing more successfully with the electrical tramways. The work of revising fares and making uniform arrangements will be immense, and some little time must elapse before it is completed.

Dundee.—The burgh engineer reporting with regard to the progress of work in connection with the laying of the new tramway in Constitution-road, states that the permanent way and the double rails have been completed between the main entrance to the infirmary and Drummond-street, and on the north line eastward from that point along Constitution-street to near Rosebank. The construction of the west line in Constitution-road has now been commenced.

Thornhill.—The General Purposes Committee have decided, in reply to an enquiry from the British Electric Traction Company, that no span wires be allowed in any of the roads along the route of the proposed light railways in the district, except where it is absolutely necessary in the cases of corners and bends in the roads. It is further resolved to request the company to lay the tramlines in Lees Hall-road and Brewery-lane not more than 4ft. from the kerb.

Hull.—At the last meeting of the Town Council, on the minutes of the Works Committee, containing a balance sheet of the cost of the electric tram system, a member criticised the management. He said that the income from the trams appeared to be practically stationary, whilst there was a large additional expenditure. It was officially explained that the increased expenditure on the tramway system arose mainly in the increased pay to the conductors and drivers and other employés of the undertaking.

South Lancashire.—The two lines of rail, upon which about 200 workmen have been engaged during the past few months from Hulton boundary through Atherton, and from Lowton boundary through Leigh, are now practically completed and joined up at Leigh and Atherton boundary. This is the first finished length of the South Lancashire Tramways Company's big scheme for uniting Manchester, Liverpool, St. Helens, Warrington, Leigh, Wigan, and Bolton, and on Coronation Day horse cars will be run.

Light Railways in Essex.—The Light Railway Commissioners have decided to sanction the scheme for a light railway from Southend to Colchester. They authorise the proposals for crossing the Rivers Crouch and Blackwater, but they provide that no existing public rights of ferry on the Crouch shall be displaced, and that no exclusive rights of ferry on the Blackwater shall be conferred on the light railway company (except between their own piers). They limit the capital to be authorised for the construction and equipment of the proposed line to £500,000.

Bradford.—A curious accident has occurred on the Thornton-road section of the electric tramways. A guard wire broke in Thornton-road, near Jesse-street, dropping across the trolley wire and thence on to the rails. Finally it came into contact with a horse and cart. According to report, the four shoes of the horse were ripped off its feet, but the animal itself was not hurt, and no other damage resulted. A service of electric cars has been commenced from Four Lane Ends to Allerton. The estimates for the proposed tramway extensions are £184,248 tramways, and £83,942 street improvements.

Birmingham.—The shareholders of the City of Birmingham Tramways Company, Limited, have received a circular from Mr. James Ross, of Montreal, chairman of the company, stating that he has agreed to sell his ordinary shares for 37s. 6d. each, net cum dividend, and arranged that a similar offer should be made to all other shareholders, the offer remaining open until 30th inst. Messrs. Ross Bros. hold together 32,727 shares, so that the price paid is £61,000. It is stated that important developments are intended by the London syndicate, who are said to be the B. E. T. Company

Private Bills.—In the House of Commons the following Bills have been read a third time: London County Council (Subways and Tramways) Bill; London County Council (Tramways and Improvements) Bill; London, Tilbury, and Southend Railway Bill; and the City and Brixton Abandonment Bill. In the House of Lords the Central London Railway (New Lines) Bill; the North Staffordshire Tramways Bill; and the Rossendale Valleys Tramways Bill have been read a third time and passed; and the Great Northern Railway Bill and the Garston and District Tramways and Electric Supply (Transfer) Bill a second time.

North Shields.—The electric tramway to Wallsend is now laid. It was originally arranged that the County Council and the tramways company should conjointly pay the cost of widening and strengthening the bridge across Willington Gut, so that double lines could be laid over it, but a difficulty has arisen regarding the purchase of the additional land required. In the meantime the company have asked the Wallsend Council to grant them permission to construct a single line until the necessary ground is secured in order that the service may be opened as early as possible. The Corporation are likely to grant the concession.

Newport (Mon.).—In the Corporation Bill which is now being enquired into by a committee of the House of Lords, powers are sought to improve the tramway system from the town to the docks. At present the tramlines are single, and stop at the limits of the old boundary of the borough. It is now proposed to double these tramways, and to extend them to the edge of the new boundary and to introduce electric traction. The only opposition to the scheme is that of the Great Western Railway Company, who object to the tramway being extended from the point in Commercial-road across the Pillgwenlly level crossing.

Sheffield.—The extension of the Hillsborough tramlines is to be carried out to join the Owlerton route from Holme-lane and Parkside-road, and the paving of the tracks will be with wood from Holme-lane to Dykes Hall-road, the remainder to be granite. The Tramways Committee have decided that a sum of £50 should be expended on the decoration of the cars on June 26 and 27, and that three prizes—viz., £2. 10s., £1. 10s., and £1—be given to the motormen and conductors of the cars which are most tastefully decorated. The Council have confirmed the policy of the Tramways Committee in favour of ceasing to run cars to Harcourt-road.

Failsworth.—At the last meeting of the District Council a letter was read from the town clerk of Manchester enclosing print of the awards of the arbitrator in connection with the purchase of the tramways. The amounts of the respective awards are £39,373 and £12,012. The value of the permanent way is the same in each award, the difference arising out of the contention between the parties as to how much of the respective depôts and of the horse cars and other plant are to be purchased and paid for by the respective purchasing authorities. The case, it was stated, is being set down for hearing at an early date, with the view of an authoritative decision being obtained.

Newton-in-Makerfield.—At the monthly meeting of the Urban District Council, a communication was read from the solicitors to the Council stating that the South Lancashire Tramways Company had subscribed an amount in excess of £733,000 under the contract of the tramways company, and the company had informed them that they proposed to proceed forthwith with the construction of the tramways in the Council's district as included in their first construction scheme. The tramways in the district will enable the section now nearly completed to Leigh and Bolton to be connected with that on the St. Helens route. That connecting the trunk line to Warrington is contained in the second scheme.

Hastings.—The Hastings Corporation by 12 votes to 14 have consented to the Front Line Electric Tramways Bill. An application in regard to the scheme was, however, made to the Earl of Morley, chairman of committees of the House of Lords, on Thursday last week. After a short argument, the Earl of Morley stated that he could not disturb the decision of the Standing Orders Committee as to the Front Line scheme, based on the original vote of the Town Council on March 7 refusing consent to the Bill. The matter thus stands in exactly the same position as it did prior to the special meeting of the Town Council—that is, the Front Line scheme cannot be proceeded with in the present session of Parliament.

Wolverhampton.—A long discussion took place at the last meeting of the Town Council with regard to the tramway deadlock, and the correspondence between the Corporation and the British Electric Traction Company on the matter was read. The subject eventually dropped, the Council deciding to deal with it in committee. On Tuesday a communication was received from the Traction Company to the effect that they were prepared to accept the proposal of the Corporation that the company should bring their system to the Wolverhampton boundary on the overhead system to meet that of the Corporation. The company are further prepared to enter into an agreement at once to carry out the work, on the Corporation undertaking to pay the cost.

Digitized by Google

Nelson.—Tenders for the supply and laying of cables for the light railways to Colne and Barrowford have been referred to the chairman of the Tramways Committee and the electrical engineer, with power to accept a tender. The following resolution has been adopted by the Town Council: "That in pursuance of the enabling provisions of the Light Railways Act, 1896, the Light Railway Commissioners be requested to confer upon the Council of this borough by means of the Colne and Trawden Light Railways Amendment Order, 1902, authority to enter into an agreement with the promoters of the said order to work or to contract for the working of the light railways authorised by the Nelson Light Railways Order, 1901, and the Colne and Trawden Light Railways Order, 1901.

Scarborough.—The Earl of Morley, chairman of committees in the House of Lords, has had under consideration the Scarborough Tramways Bill, the object of which is to incorporate the Scarborough Tramways Company, and to empower them to construct and maintain tramways and to execute certain street works in the borough. The capital power sought is £96,000, with the usual borrowing powers of one-third. The Bill enables the Corporation to subscribe or lend an amount not exceeding £10,000 towards the undertaking, and entitles the mayor or other member of the Council to become an *ex-officio* director of the company in the event of the Council having an interest in shares of the company to the extent of £5,000. The preamble having been formally proved, the Bill was sent for third reading in the House of Lords.

Newcastle.—A further extension of the electric tramways has been brought into service—viz., the Clayton-street route. Every second car leaving the Osborne-road terminus will now run to Elswick-road *via* Northumberland-street, Blackett-street, Clayton-street, and Westgate, and *vice versa*. In connection with this change, the cars that up to Saturday were running between Elswick-road and Heaton-road *via* City-road are now running between Westgate-road and Union-road *via* City-road and Raby-street. A supplementary service is also working between Westgate-road terminus and St. Nicholas's-square and Elswick-road terminus and St. Nicholas's-square. These practically mean a continuous four minutes' service from the West-end termini to the station, with the advantage that there will not be so many stoppages opposite St. John's Church.

Wakefield.—It will be within the recollection of our readers that the application for powers to construct a tramway to Dewsbury in connection with the Wakefield scheme fell through, and since then nothing appears to have been done in Wakefield. Enquiries have been made by the West Riding County Council, the Wakefield Corporation, and the Tradesmen's Association as to when a start will be made by the promoters, but no definite answer has been given. The promoters are allowed three years in which to make a start (of which one year has elapsed), but the time may be extended if sufficient cause can be shown. It is reported that the local solicitor of the promoters of the light railways scheme is expecting instructions to make fresh application to Parliament for powers to construct the proposed line to Dewsbury, *via* Ossett, which has once been refused by the Light Railway Commissioners.

Tyneside.—The Court of Referees of the House of Commons has had under consideration an objection raised to the North-Eastern Railway Company being heard against the Tyneside Tramways and Tramroads Bill. Mr. Mooney, K.C., for the North-Eastern Railway Company, said there were two grounds on which he asked the court to give a *locus standi*. One was on the ground of competition, and that related not only to passenger traffic, but to goods and mineral traffic. The second ground on which he asked to be heard was that of interference with works. In some places the tramways would pass under the North-Eastern Company's bridges, and it was intended to alter the level of the road. The result might be, and it very likely would be, that the foundations of the bridges would be interfered with. He thought the promoters must concede his right to be heard for the protection of those bridges. The *locus standi* was disallowed.

Hampstead.—The General Purposes Committee report that they have instructed the town clerk to obtain from the London County Council fuller details of the proposed scheme for constructing a tramway from Edgware-road to Child's Hill, and also from the Middlesex County Council fuller details of the proposed scheme for constructing tramways in the county of Middlesex, as set out in the notice of proposed application to the Light Railway Commissioners. With regard to the Charing Cross, Euston, and Hampstead Railway Bill now before Parliament, the Borough Council have resolved that, having regard to the fact that the necessary provisions for the protection of the borough have been inserted in the Bill, and being of opinion that the construction of the proposed railway would supply a good public need, the Council trust that the borough member will not only see his way to refrain from any contemplated opposition to the Bill, but will give it his cordial support when it comes before the House of Commons.

Stoke-on-Trent.—At the last meeting of the Town Council, Mr. Stephen Sellon, chief engineer to the British Electric Traction Company, wrote regretting that the Council had decided that a double line on the proposed light railway from Stoke, through Hartshill, to Newcastle, was not advisable in certain portions of the route. He considered the double line so essential, that it would be necessary for him to make application to the Board of Trade to appoint an arbitrator to decide this matter if they could not come to any understanding. The town clerk was instructed to write to Mr. Sellon, pointing out that no double line was shown on the original plan deposited on the application for the order, and stating that the Light Railway Sub-committee, with the borough surveyor, had taken a great amount of trouble in further considering the matter, and could not see their way to recede from the position they had taken up, but were prepared to meet Mr. Sellon at the *locus* and give their best attention to any argument he might use in support of his contention.

Manchester.—It is decided to invite tenders for a new type of car to be used on the circular route of tramways which will link the suburbs of the city together. As there are several low railway arches on these routes, a single-deck car has been adopted. The new car differs from the old in that a portion of it will be open at the sides. It will be constructed to hold 18 passengers in the central portion and 10 at each end. The electric tramways worked by the Corporation earned £5,180 last week, and 1,112,000 passengers travelled on the cars. In the previous week £2,761 was received from 689,863 passengers. This large increase was due to the opening on June 1 of the routes to Stockport and Denton. There are 50 miles of single track now worked by the Corporation. When the proposed scheme is complete the system will embrace 150 miles of single track. The greater part of the 100 miles to come in is upon routes still worked by the horse cars of the Manchester Carriage and Tramways Company. Yesterday the company began the sale of a further batch of 720 horses not now required.

Blackpool and Garstang Light Railway Co.—This Company has been incorporated with a share capital of £180,000 in £10 shares, and power to borrow £60,000, for the purpose of constructing and working about 14 miles of railways from Blackpool to Garstang, connecting with the London and North-Western and the Lancashire and Yorkshire Railways. The railway will give access to about 40 square miles of the most fertile part of the Fylde district, and it is expected that an immense quantity of agricultural and market garden produce will be available for transport to Blackpool, as well as to the trunk lines of the North-Western and Lancashire and Yorkshire Railways. The directors also expect that the company will derive all the advantages of interchange of the passenger traffic from the Blackpool and Fleetwood tramroad and the railways already mentioned. Tenders amounting to £148,112 have been received for constructing the railway and buildings, and it is thought that a portion of the line will be open for public traffic in the summer of 1903. Eighteen thousand £10 shares are now offered for subscription. The subscription list closes to-day (Friday).

Aberdeen.—The financial year of the Corporation tramways closed on Saturday last. The total receipts for the 12 months amounting to about £37,000, which gives an increase of some £2,225 on the preceding year. The details as to the expenditure are not yet available, but it is believed that there will be a substantial balance on the right side. The number of passengers carried during the year was 9,089,215, while for the preceding 12 months the figures were 8,361,711, showing an increase of 727,504. The Tramways Committee have decided to recommend to next meeting of Council that a single tramway be laid from Union-street to Ferryhill Free Church, along Crown-street and Ferryhill-road. The committee have decided to appoint a delegate to join with other corporations, notably Glasgow, Manchester, and Dundee to make a representation to the Board of Trade in regard to the rules which are issued from time to time by the Board in reference to the overhead wires and other matters. The Board of Trade inspection of the Albyn-place and Bayview, Holburn-street, and King-street sections of the electric tramways took place one day this week, thus completing the inspection of the whole of the existing tramway system in Aberdeen.

Light Railways Report.—The report of the proceedings of the Board of Trade and of the Light Railways Commissioners up to Dec. 31 last, under the Light Railways Act, 1896, is published as a parliamentary white paper. Since the date of the last report the Treasury have conditionally agreed to make the following advances in respect of light railways authorised by orders confirmed by the Board of Trade: South Norfolk—£24,350 as a free grant; Leek, Caldon Low, and Hartington (Waterhouses to Hulme End section)—£2,500 as a free grant and £7,500 as a loan with interest at 3 per cent. per annum, in addition to £15,000 previously promised; Tanat Valley—instead of the free grant of £28,000 previously promised, a free grant of £22,000 and a loan of £6,000, without interest, have been agreed upon, in view of altered circumstances. Lauder: £11,000 as a loan under Section 4 of the Act, with interest at 3¼ per cent. per annum. The Treasury have also conditionally agreed to advance a further sum of £7,000 as a free grant and £3,500 as a loan, without interest, in addition to £37,500 previously promised, in respect of the Cromarty and Dingwall light railway, the order to authorise which has recently been submitted to the Board of Trade, but has not yet been confirmed.

New Issue.—The Havana Electric Railway Company are inviting subscriptions for an issue of 7,500,000dol. 5 per cent. consolidated mortgage 50-year gold bonds, part of a total authorised issue of 10,000,000dol., at the price of 98 per cent., or 980dol. per 1,000dol. bond. The prospectus states that the company has been incorporated under the laws of the State of New Jersey, to acquire the concessions and property of the Ferro Carril Urbano y Omnibus de Habana (Havana City Railway and Omnibus Company), a local concern organised in 1876, for the construction and working of tramways in the city of Havana. The company is now, in its first year of operating, earning a gross revenue of from 1,100,000dol. to 1,200,000dol silver currency. The cost of the franchises, the old system, the construction of the new system, together with the electrical equipment, electric cars, car stations, and power station of sufficient size for extended future requirements has been about 7,000,000dol., and the proceeds of the present issue, less the amount required to redeem the outstanding bonds of the company, will be used for further extensions of the system, additional rolling-stock, etc. The bonds will be repayable by the operation of a sinking fund, or redeemable at the option of the company on six months' notice at 105 per cent.

London County Council Subways Bill.—In the House of Commons last week there was a long discussion on the consideration of the London County Council (Subways and Tramways) Bill as amended. The main object of the Bill is to authorise a subway for trams from north to south in London, the subway terminating near

Digitized by Google

the north end of Waterloo Bridge, from which point the tramway would be continued to Westminster Bridge on the open thoroughfare of the Embankment. Mr. Whitmore moved a new clause as follows: "Notwithstanding anything in this Act contained to the contrary, it shall not be lawful for the Council to construct any tramway southward of the southern boundary of the premises No. 6 in the precinct of the Savoy upon the deposited plans." He strongly condemned the Bill as it stood as a measure which would result in disfigurement to the Embankment and in obstruction to traffic on that thoroughfare. Mr. H. Hobhouse, who was chairman of the committee on the Bill, asked the House to dismiss from their minds the fear that the system involved disfigurement of the Embankment, or the ultimate construction of a line over Westminster Bridge. There were other ways of crossing the Thames than that, and when a specific proposal for extending the line was made the House could deal with it on its merits. Finally, the new clause was rejected on a division, and the Bill was ordered for third reading.

London United Tramways.—Mr. Compton Rickett's Committee of the House of Commons, who are enquiring into the proposals of the above Bill, this week heard evidence in support of those portions of the scheme which affect the Wimbledon district. Mr. W. S. Bond, chairman of the Parliamentary Committee of the Wimbledon Urban District Council, who conducted the negotiations with the promoters, claimed that the agreement arrived at was eminently satisfactory for the ratepayers. The widenings and improvements would distinctly be advantageous to Wimbledon. These conditions the British Electric Traction Company would not accept, and communication with that company on the subject was discontinued last year. The general feeling among the inhabitants of Wimbledon was in favour of the tramway proposals, and this was shown by the unopposed return of five candidates in favour of the Bill in local elections last April. Even without the expenditure of £165,000 now proposed by the promoters on Wimbledon improvements, the tramway service would be of great advantage to the town, and especially for the working classes, for whom the railway facilities were inadequate, and as a convenient means of intercommunication with Malden, Kingston, and Hampton Court. He did not think that the construction of the tramway along Worple-road would lower the ratable value of property on the route. The tramway to the common was an important part of the scheme, and from the first had been included in the negotiations between the Council and the company. Mr. Balfour Browne, K.C., in reply to the chairman, said the promoters would be quite prepared to lay down a length of about 300 yards to connect their proposed No. 13 line with the London County Council tramway to Tooting, and Mr. Talbot undertook to communicate with the County Council, this short spur coming within the area of their administration. The committee adjourned.

Southport.—The report of Mr. T. G. Kendrew, the Corporation tramways manager, for the year ending March 31 last, states that there are at present 26 electric cars and two horse cars available for service. With the exception of one single-decked car, all the equipments are Preston make and interchangeable. Three of the new cars are fitted with the Tidswell patent lifeguard at each end, and the other is fitted with the Newton patent lifeguard. To facilitate the working of the heavy traffic along Scarisbrick New-road it was decided on the expiration of the Birkdale and Southport Company's lease to replace a short single line opposite to Seaton-street by double track, and this has proved of great service. No accidents have occurred through the falling of wires. There has been no breaking of any copper wires; this is due to the periodical examination of the overhead equipment, and doing small repairs when necessary. Efficient guard wires are fixed where telephone wires cross the track. These have been found very effective whenever a telephone wire has fallen, either keeping it off the trolley wire or fusing it when making contact with same. In no instance have the cars been stopped on account of falling telephone wires, as was the case on Friday, March 29, 1901, and only very rarely have the cars been delayed through accidents of any kind. The reconstruction of the lines leased to the Southport Tramways Company, Limited, was commenced on March 11, 1901. The first electric car was run from Manchester-road, *via* Cambridge-road, to the Botanic Gardens on June 5, 1901. The line from Duke-street to Botanic Gardens, *via* Cambridge-road, was inspected and passed by the Board of Trade on Sept. 9, the whole of the overhead equipment and track being completed within six months. A full set of tools is supplied to each car, in which rubber gloves and pliers are included, also a key of the section boxes, so that the fuse can be replaced as soon as possible after the broken wires have been cut clear. A lathe, drill, and other tools are on order, and will be working shortly at the depôt, so that our repairs may be carried out without delay. The whole of the lines, cars, electrical equipments, and equipments have been kept in first-class condition.

London County Council.—At the meeting of the London County Council on Tuesday the Parliamentary Committee reported the fact that the Select Committee of the House of Commons presided over by Mr. H. Hobhouse have passed the Tramways and Improvements Bill, authorising the following: the construction of tramway lines from Hammersmith-broadway *via* Putney Bridge to Lower Richmond-road; along the Victoria-embankment from near the western end of Westminster Bridge to join the Council's proposed shallow underground tramway to Theobald's-road at a point near Waterloo Bridge; from Eltham *via* Wellhall-lane and Woolwich-road to Beresford-square, Woolwich; from Camberwell-green *via* Grove-vale, Dog Kennel-hill, and Lordship-lane to the junction of the last-mentioned thoroughfare with Crystal Palace-road; widenings of Hampstead-road; Denmark-hill, Champion-park, Grove-lane, Dog Kennel-hill, Grove-vale, and Lordship-lane; Fulham Palace-road and High-street, Fulham; and Queen's-road, Peckham; the utilisation of the Council's Greenwich tramway depôt and land adjoining to be acquired for the purpose of an electricity generating station; the acquisition of land at New Cross-gate and Clapham for the purposes of a tramway depôt and the enlargement of an existing depôt respectively. The Parliamentary Committee also presented a report on the various "Tube" Bills which have been dealt with by the Lords' committees presided over by Lord Windsor and Lord Ribblesdale respectively. The Highways Committee recommended the Council to pass the statutory resolutions authorising them to require the Woolwich and South-East London Tramways Company, the South London Tramways Company, and the London, Deptford, and Greenwich Tramways Company to sell their undertakings to the Council. The tramways in question are mainly those from Vauxhall Bridge to Westminster Bridge, from Albert-embankment to Vauxhall Bridge, along a part of Southwark-street to Borough High-street and from St. George's-road to the Elephant and Castle. Reporting on the financial aspect of these purchases, the Finance Committee state that they had thought there was a reasonable prospect that the lines would prove remunerative, but the South London Company has lately suffered from the rise in working expenses which has been experienced by all such undertakings, and the latest available figures show a considerable falling off in the net earnings. On the basis of the present cost of horse traction, and the Council's standard of wages and labour, and apart from the connections which can be made with the Council's lines, it appears to them very doubtful whether the undertaking could be worked by the Council at a profit. Dealing with the undertaking of the London, Deptford, and Greenwich Company, the Finance Committee express the view that this can only be worked at a loss unless it can be acquired on very favourable terms. Besides, full advantage cannot, they say, be obtained until electric traction has been adopted over the whole of the lines, and this may involve considerable street widenings, as to the cost of which no estimates have as yet been prepared. On the question of the proposed electricity generating station at Greenwich, the Highways Committee presented the following report: "We have had under consideration the question of the manner in which water required for feeding the boilers of the electricity generating station to be erected at Greenwich may best be obtained. The cost of obtaining the water from the available public supply when the station is finally completed would be between £5,500 and £6,000 a year, and it has been suggested to us that, in order to avoid the necessity for this large expenditure, surface condensers shall be used at the station, and water obtained by means of a well to be sunk on the site. Should this course be adopted, it is anticipated that the annual cost of providing water for the feeding of the boilers will not exceed £300, but it will be also necessary to provide, at a cost estimated at about £300 per annum, a large amount of water for the general purposes of the station, so that the total annual cost for water will be about £600. Well borings have been made near the river at Greenwich with a view to ascertaining the suitability of the water obtained from the chalk or below it for boiler-feeding purposes; but the results have been somewhat conflicting, and it appears to us, therefore, to be advisable that a trial boring hole should be sunk at the site to a sufficient depth to tap the best water bearing strata. We have obtained prices from four firms experienced in such work, and, assuming that the boring would be 300ft. deep, these prices, which will be less should suitable water be found at a higher level, work out as follows: Messrs. Le Grand and Sutcliffe, £310 for 8¼in. borehole; Messrs. Merryweather and Sons. £395 for 9in. borehole; Messrs. C. Isler and Co., £545 for 10in. borehole; Messrs. Dowcra and Co., £592 for 9in. borehole. The prices above quoted are in respect of the boring, the erection and removal of the boring, plant, and the use of trial pumps for the purpose of ascertaining the quantity of water available. We are of opinion that it is advisable that the offer of Messrs. Le Grand and Sutcliffe should be accepted, and we recommend that the estimate of £350, submitted by the Finance Committee, be approved; and that the expenditure be authorised of a sum not exceeding that amount in connection with the boring of a trial wellhole at the site of the proposed electricity generating station at Greenwich; that the offer of Messrs. Le Grand and Sutcliffe to carry out the work at the prices specified in their letter, dated April 22, 1902, to the tramways manager be accepted; that it be referred to the clerk of the Council and the solicitor to take the necessary measures to give effect to the arrangement; and that the seal of the Council be affixed to any necessary document in connection therewith." The applications of the Middlesex County Council and of the Crystal Palace Light Railway Syndicate to the Light Railway Comsioners for orders will be opposed by the London County Council.

LIGHTING AND GENERAL.

Broughty Ferry.—Sanction has been obtained to the borrowing of £15,000 for electricity purposes.

Morecambe.—The charge for current through the prepayment meters is to be at the rate of 6d. per unit.

Shoreditch.—The Corporation's electric light and power station at Haggerston will be opened on the 16th inst.

Bournemouth Telephones.—A special committee has been appointed to consider the question of telephones.

The North Metropolitan Electric Power Supply Bill.—This Bill has been read a second time in the House of Lords.

Finchley.—An enquiry has been held into the application of the District Council to borrow £35,000 for electric lighting purposes.

Paddock Wood.—The National Telephone Company have opened their telephone exchange. There are already some 30 subscribers.

Rotherham.—The Town Council have granted a number of increases of salary to the staff of the electric light and tramway department.

Gloucestershire Electric Power Bill.—This Bill has passed through its committee stage in the House of Lords without opposition.

Digitized by Google

Bristol.—It is proposed that 365 arc lamps be erected in main roads running out from the old city boundary to the new, and in the city.

Hull.—Lord Hawkesbury's Select Committee on Tuesday refused to allow the National Telephone Company (Kingston-upon-Hull) Bill to proceed.

Elland.—The District Council have decided to apply to the Public Works Loan Commissioners for a loan of £16,000 for dust destructor and electricity works.

Camborne.—The order granted by the Board of Trade to the electric light company is being considered by the Lighting and Town Improvement Committee.

Admiralty Appointments.—The Admiralty have authorised the entry of 125 electricians in the navy during this year, bringing the strength of this branch to 200.

Battersea.—The Council are obtaining a loan of £6,000 for providing and laying mains and services in connection with the electric lighting of the borough.

Edison Accumulator.—It is stated that the new Edison storage battery is now on the market. The plant for its manufacture at Silver Lake, New Jersey, United States, is completed.

Saltburn.—The District Council are discussing the question of lighting the town with electricity, and have made application to a company for the terms upon which a current can be supplied.

Torquay.—A minimum charge of 10s. per year is to be made in future to every consumer connected with the Corporation's electric lighting system who is not regularly using the light or current.

Durham.—The extension of the electric light from Rock House, New Brancepeth, to Allen Waters, in place of the existing oil lamps is proposed. The surveyor is preparing an estimate of the cost.

German Atlantic Telegraph Co.—The German Atlantic Telegraph Company propose to raise £1,000,000 by the issue of 4 per cent. bonds in order to provide the means for the construction of a second cable.

Transvaal and Orange River Colonies.—The civil administration will take over the telegraphs and telephones in the Orange River and Transvaal Colonies from July 1, subject to Lord Kitchener's final approval.

Eastbourne.—The last report of the borough accountant (Mr. John Allcock) on the accounts of the electric lighting undertaking, showing a profit of upwards of £3,000 in 12 months, is exceedingly gratifying.

Kingston (Surrey).—The Town Council have requested the Lighting Committee to obtain expert advice on the electric lighting works, and empowered them to spend a sum of money not exceeding £100 on the matter.

Failsworth.—A sub-committee is to wait upon the Electricity Committee of the Manchester Corporation and enquire on what terms they would be prepared to undertake such supply now that their electricity scheme was more matured.

Hackney.—The Borough Council have decided to invite tenders for an electric motor, estimated to cost £100, as the most suitable and economical means of driving the laundry machinery at the new disinfecting station at Millfields.

Dewsbury.—Sanction has been given to arrangements made by the Electricity Committee with the new tramways company for the laying of additional lighting mains in the cable trench of the company along Bradford-road to the Market-place.

Dutch-German Cable.—The Second Chamber of the States General at the Hague have adopted a convention between Holland and Germany regarding the cable service to the Dutch Indies to be worked by a Duch-German company.

Ayr.—The last report of the electric engineer shows that the number of new consumers connected during May has been 15, bringing the total up to 552, the number of lamps added during the same period being 301, bringing the total up to 23,116.

St. Marylebone.—The Guardians have referred the proposed electric lighting of the infirmary to the Infirmary Visiting Committee, who are to report upon the expenses connected with taking the current from an outside source, and for wiring the building.

Wireless Telegraphy.—Six firms have responded to the invitation of the United States Signal Office to instal wireless telegraphs in Alaska. Among them are the Marconi Company, of London, the Slaby-Arco, of Germany, and three American companies.

King's Lynn.—At the last meeting of the Board of Guardians it was reported that the Corporation's charge (cost price) for putting in an electric light installation at the workhouse was £145. 10s. The cost had been put down before as "not exceeding £148."

Warrington.—Electric light is to be supplied to places of public worship at a uniform charge of 3½d. per Board of Trade unit, and the price of current for Coronation illuminations will be reduced to 3d. per Board of Trade unit during the evenings of 26th, 27th, and 28th inst.

Harrogate.—The engineer's salary has been increased by £100 per annum. Several other increases have been granted. The charge for street-lighting will be reduced from 2½d. to 2d. per unit, but no alteration is to be made in the charge for domestic supply of electric light.

Durham.—The Durham County Electric Supply Company are making good progress with their lighting intallation at Jarrow. The mains are in, the power station in Beech-street is approaching completion, and it is expected that the current will be turned on within a month.

Obituary.—The death is announced of Sir Daniel Cooper, chairman of the Electric Construction Company, Bushbury, in his eighty-first year. He was previously associated for many years with New South Wales, where he was the first Speaker of the Legislative Assembly at Sydney.

Provisional Orders.—The Electric Lighting Provisional Orders Bills, Nos. 4 and 7, which recently passed the second reading stage in the House of Lords, include orders to Amble, Leadgate, Stanley, Morpeth, Ashington, Newbiggin-by-the-Sea, Morpeth (rural), and Chepstow.

South Wales Electrical Power Bill.—The Committee of Selection in the House of Lords have nominated the following peers to consider the above, among other private Bills: Lord Brougham and Vaux (chairman), the Earl of Romney, Lord North, Lord Colchester, and Lord Muncaster.

Sleaford.—The Electric Lighting Committee in their last report state that if the demand for the light continues a further engine and dynamo will be necessary. It is proposed to lay a new cable to the motor at the sewage pumping station. The electrical engineer estimates the cost at 7½d. per yard.

Huddersfield.—The negotiations for the establishment of electrical engineering works at Huddersfield are being continued, but no substantial development has so far resulted. It transpires that no inspection has yet been made of the Prague works by an electrical expert on behalf of the proposed company.

Sevenoaks.—At the last meeting of the Urban District Council attention was called to the fact that nothing appeared to have been done by the Kent Electrical Power Distribution Company under their provisional order. It was decided to ask the company for a definite statement as to what they proposed to do in the matter.

East Barnet Valley.—We understand that at the next meeting of the Urban District Council a resolution will be proposed with a view of rescinding a prior resolution, in order to enable the Council to reopen negotiations with the North Metropolitan Electrical Power Distribution Company on the subject of electric lighting.

Bexhill.—The report on the second year's working of the electric light in the town up to March 31 last shows a total revenue of £4,814. 6s. 10d., and a total expenditure of £2,736. 14s. 7½d., leaving a gross profit of £2,077. 12s. 2½d. Interest and sinking fund amounted to £1,654. 19s. 10d., leaving a net profit of £422. 12s. 4½d.

London County Council.—On Tuesday the Council agreed to lend the Stoke Newington Borough Council £3,000 for electric light installation, street-lighting, and meters. Sanction was also given to a loan of £26,100 to the Hampstead Borough Council for electric lighting and meters, and to the Stepney Borough Council £95,642 for the same purpose.

Desk Fans.—Johnson and Phillips are introducing electric desk fans, for which they claim efficiency, durability, and artistic appearance. The current taken to drive a 12in. is only about the same as for an ordinary incandescent lamp. They are made entirely at the company's works at Charlton in two sizes—*i.e.*, from 100-125 volts and 200-250 volts.

Stockton.—The Electric Light Committee have decided upon the following revised scale of charges for electricity: under 250 hours of maximum demand per quarter, 2½d. per unit; under 500 hours of maximum, 2d. per unit; and special terms by arrangement for larger consumers. The charges for places of worship is to be reduced to a flat rate of 4d. per unit.

Newcastle.—The Gas and Electricity Committee have considered a communication from Messrs. Rowcliffe and Co., solicitors, Manchester, notifying their intention to apply on behalf of a syndicate for parliamentary powers to erect generating stations and lay mains for the supply of electricity throughout North Staffordshire. It is proposed to oppose the application.

Ryton.—The surveyor (Mr. J. P. Dalton) has prepared a report upon the lighting of Greenside by electricity in the event of the offer of the Stella Coal Company, Limited. Twenty-two lamps will be supplied with current for £2. 10s. each per 50-c.p. lamps for the lighting season. Twenty-two lamps were estimated to cost £66. The question has been adjourned for two months.

Hornsey.—A number of tradesmen and residents in Turnpike and Vernon-road, Hornsey, have written to the District Council stating that they contemplated using the electric light either for private or business purposes, and pressing the Council to erect large arc lamps along the whole length of Turnpike-lane, but the Council replied that that cannot be done beyond Alexandra-road at present.

Coronation Carrillon.—A peal of 18 electric bells has been erected in Salisbury for the purpose of playing the National Anthem, etc. Mr. E. R. Dale, A.I.E.E., The Ford, Fisherton, Salisbury, who is responsible for the installation, informs us that his system can be applied to the heaviest of church bells, and that by its means tunes can be played on them by electricity as easily as on a piano or organ.

Wave-Motor.—It is reported that a wave-motor, or motor worked by the waves of the sea, has been installed at Avalon, California, by Mr. H. Banning, of the Wilmington Transportation Company, to work a fog-bell and pump salt water into a reservoir for watering the streets of the town. It can also be used for pumping out ships, and it is thought it could be utilised in generating electricity either directly or by filling a dam.

Chesterfield.—The minutes of the Electrical Energy Committee showed a gross profit of £867. 17s. 7d. for five months' working. The British Westinghouse Electric and Manufacturing Company, Limited, have received an order from the Bolsover Colliery Company, Limited, for a complete polyphase electric power installation. The power will be used principally for hauling and pumping purposes in the colliery workings.

Berwick.—At the last meeting of the Town Council the clerk read a letter from the solicitors to Messrs. Edmundsons, Limited, who

Digitized by Google

obtained a provisional order to introduce electric light into Berwick, stating that they expected to make a commencement very shortly. It was thought the reply was very indefinite, and as the time for the provisional order was stated to have expired, the clerk was instructed to write again, and ask that a time might be specified for the beginning of the work.

Wakefield.—The electrical engineer in his last report states that, in order to cope with the load during the winters of 1902-3-4, extensions will have to be carried out at the works, including the erection of an additional 800-kw. plant and the provision of additional transformers, boiler, and mains. A recommendation that application be made for sanction to borrow a sum of £15,000—the estimated cost of such extensions—has been referred to the sub-committee of the Electric Lighting Committee.

Coventry.—Major Norton has held an enquiry into an application of the City Council to borrow a further sum of £20,480 for the electric light undertaking, and £2,000 for the purchase of electric motors to be hired out to manufacturers. The town clerk (Mr. L. Beard) in his evidence alluded to the increasing demand for electric motor power, the readjustment of rebates, a slight reduction in price, and the improvement of £800 on last year's working profit of the undertaking, and an improvement of £450 in the net profit.

Bury St. Edmunds.—At Tuesday's meeting of the Council the electrical engineer reported to the Electric Lighting Committee that during May applications for 71 8-c.p. lamps had been received, and cables for arc lamps in Abbeygate-street and Angel-hill had been laid. The premises of seven new customers in Churchgate-street had been connected with the new cable in that street. The Council agreed that the actual cost of the current consumed—1d. per equivalent 8-c.p. lamp—be the charge for illuminations for the Coronation festivities for each night from 8.30 p.m. to midnight.

Lowestoft.—There are now connected to the mains 251 consumers, representing a total of 11,785 8-c.p. lamps. Applications for 1,352 8-c.p. lamps to be connected are in hand. During the last month nine extra consumers, representing 290 8-c.p. lamps, have been connected. Local authorities within a radius of six miles from the borough boundary are to be notified that the Council intends to apply for a provisional order for the supply of electricity outside the borough to the parishes coming within that radius. The salary of the resident engineer is to be increased to £250 a year, to date from March 25 last.

Pocklington.—A month ago the Urban Council passed a resolution to the effect that they thought it desirable that a Post Office telephone exchange should be established in the town, but at the last Council meeting a letter was read from the Postmaster-General pointing out that the expense of establishing the necessary trunk communication between York and Pocklington would be "very considerable," and that, providing a sufficient number of subscribers were not forthcoming, a guarantee would be asked for. The councillors thought the prices would be prohibitive, and the matter, therefore, will be allowed to rest in abeyance.

Stock Exchange.—The Stock Exchange Committee have ordered the undermentioned securities to be quoted in the official list: British Westinghouse Electric and Manufacturing Company's further issue of 50,000 6 per cent. preference shares of £5 each, fully paid, Nos. 150,001 to 200,000; Eastern Telegraph Company's further issue of £102,377 4 per cent. mortgage debenture stock. Applications have been made to the committee to appoint a special settling day in and to grant a quotation to Charing Cross and Strand Electricity Supply Corporation's 40,000 "City Undertaking" 4½ per cent. cumulative preference shares of £5 each, fully paid.

Aston.—Mr. E. A. Sandford Fawcett has held an enquiry into the Council's application for sanction to borrow £52,436 for electric lighting. The foundations of the generating station have been partly got out, the Council being under obligation to build the station for tramways, which are to be electrically equipped. Mr. T. Ansell, the town clerk, said the Council had had numerous applications from manufacturers asking when they would be able to be supplied with electrical energy, and all pressing on the Council the necessity for making such a provision. Mr. Wilson, the consulting electrical engineer, explained the technical details.

New Issue.—Willans and Robinson, Limited, are issuing at par £250,000 4 per cent. first mortgage debenture stock, of which £105,000 is to be utilised to retire the existing 4½ per cent. debentures, £10,000 is to be held in reserve, and £135,000 is now offered to the public for subscription. The new capital is required for completing the works at Queen's Ferry and Rugby, for providing additional plant and machinery, and for other purposes. It is stated that since the removal of the headquarters of the company to Warwickshire in 1897, the net trading profits, including that year, have averaged over £51,000 per annum, and in 1901 showed an increase of £1,300 over the previous period.

Blackpool.—The electric lighting revenue account for the year amounted to £27,911. 17s. 7d., made up as follows: private lighting, £15,748; tramway current, £6,123; public lighting, £5,916; sundries, £94. The expenditure totalled £17,720, leaving a gross profit of £9,192. The units generated in the year to March last are 22,262,516, against 1,760,469 last year, being an increase of over 23 per cent. At March 31, 1902, there were 930 consumers and about 90 miles of electric lighting mains. There are 260 public arc lamps and 290 incandescent lamps. The capital outlay for the year was £25,939. The total electric lighting capital stands at £167,493, and the accumulated sinking funds at £14,925.

Mexborough.—An arrangement has been arrived at whereby the Highways Committee will pay to the Electric Lighting Committee for street-lighting £3 per annum per pillar, and £15 per annum for arcs, including incandescent lamps, such cost to include all repairs, maintenance, cleansing, etc. The electrical engineer (Mr. Waring) has presented a statement of the estimated and actual expenditure, and the committee are congratulating the Council and the town on the fact that the entire lighting, together with some extras that were not foreseen and provided for, had been done for some £300 within the original estimate of £12,000. The services of Mr. Waring, the engineer, have been retained for a further period of three months.

Glasgow.—It is estimated that the Corporation's electricity department will show a revenue of £104,000 for 1901-2 as against £79,449 for the previous year. The total number of units sold will probably be found to reach 9,200,000 as compared with 6,813,000 last year. This increased output has been produced at a cost for fuel of £13,550, while the previous year's production cost £19,667 under this head. This reduction is partly brought about by the reduced average price of fuel, which has been 8s. 1d. per ton as compared with 11s. 9d., and partly by the increased economy of working in the new generating stations at Port-Dundas and St. Andrew's Cross. The actual quantity of fuel consumed has been 33,216 tons, as compared with 33,468 tons during the previous year. Therefore, the output has increased by about 34 per cent., while the fuel consumed shows an actual reduction of 252 tons.

Grantham.—With regard to the order of the Urban Electric Supply Company as the undertakers for the supply of energy under the Grantham Electric Lighting Order, 1900, the Town Council have decided not to offer objection to the proposed continuous-current direct-supply low-pressure service, with a three-wire system with the intermediate conductor being "earthed" at the generating station, on the condition that a copy of the proposed continuous record of the current from the intermediate conductor to earth at the generating station shall be forwarded monthly to the Council, and on the further condition that the undertakers before they commence work for the establishment of the three-wire system having a pressure between the outers of 550 volts shall, in accordance with the terms of their Act, "declare the constant pressure of pressures" at the consumers' terminals which they will adopt.

Personal.—We are informed that Mr. Arnold G. Hansard, A.M.I.E.E., after many years of service with the Brush Electrical Engineering Company, during which time he held various responsible posts, including at one time the direction of all the company's electrical designing in succession to Mr. W. M. Mordey, has now started as consulting engineer at 92, Victoria-street, Westminster.—The chairman and members of the Lighting Committee of the Shrewsbury Corporation presented a marble clock with inscription and a pair of bronzes, and the staff at the electricity works presented an aneroid barometer with inscription, to Mr. C. M. Johnston, the borough electrical engineer, on the occasion of his marriage, June 5, at St. Thomas's, Lancaster.—Mr. E. Dewar, assistant engineer at the High Wycombe electric light works, has been presented by the staff and employés with a gold chain on his departure from the town.

Colchester.—Colonel Smith has held an enquiry into the application of the Corporation for leave to borrow £8,500 for further electric light extensions. The Town Clerk stated that the current was first supplied in December, 1898, the capital expenditure being £14,900. From the outset the undertaking had been a great financial success, and in 1900 a further loan of £6,500 was necessary. The demand for current increased so greatly that by September, 1901, another loan of £15,825 was sanctioned for additional land, buildings, and plant, but last winter the demand was so great that the boiler power had to be continuously used, it being impossible to stop for cleaning or repairs. The loan now asked for was to enable the Council to provide still more boiler power and buildings. The actual amount required would be £8,172. The estimate for building was £2,870, and the accepted tender was £2,242, which reduced the total from £8,500 to £7,872. Adding £300 for a balancer not included in the original estimate, the amount asked for was thus £8,172.

Bury.—At the last meeting of the Town Council Councillor Duxbury, chairman of the Electricity Committee, said the gross profit had for the last year amounted to £2,356. 15s. 6d., as against £1,274. 12s. 6d. last year. The working expenses had been very considerably reduced in the manufacture of electricity during the year, but the interest account had risen something like £430, and the sinking fund had risen also. Compared, the interest and sinking fund was £2,515. 17s. 9d., against £1,932. 5s. 3d. The net loss this year was £158, as against £657 last year. That was very considerably reduced, and he thought that next year they would be able to make a profit instead of a loss. They had had an increase of 51 consumers this year, with 6,109 8-c.p. lamps. The number of consumers on the books was 305, with 24,668 8-c.p. lamps. The output had increased this year 62,090 units, equal to 23 per cent. For motors and hiring purposes there had been 59,773 units sold, as compared with 24,471 last year, an increase of 144 per cent. Councillor Spencer, in seconding the motion, said he thought they were making substantial progress, and that before very long they would be on the right side. One factor they were looking forward to to assist them was motors. What they wanted was a use of electricity during the daytime. Their expenses were just the same whether their place was worked or not; therefore, whatever they could get in the daytime was an advantage to them. Motors would be let on hire on the same lines as gas stoves. They had had 19 motors, equal to 89 h.p., added to their stock during the year and let out on hire. That was a substantial gain. The total number of motors in use now was 48, and the total horse-power was 187. The minutes were adopted.

Brighton.—Mr. H. Percy Boulnois has held an enquiry into the application of the Town Council for sanction to borrow the sum of £1,791 for purposes of their refuse destructor and the sum of £5,500 for purposes of supplying electrical energy. The deputy town clerk (Mr. Talbot), the borough engineer and surveyor (Mr. Francis J. C. May, M.I.C.E.), the electrical engineer (Mr. Christie), and the borough accountant (Mr. H. M. Stevens) gave evidence. Mr. Talbot stated

Digitized by Google

that under the existing conditions the plant which had been provided for the supply of electricity to the town was considerably overloaded, and that in order to produce the amount of current required it was necessary at times to run the spare set. In order to increase the capacity of the plant it was proposed to instal a 325-kw. storage battery, and the effect of this would be to double the power of the existing installation. The development was necessitated so that extra working power might be provided for the trams. Mr. Christie gave the particulars of the estimated cost, and said it was proposed to utilise a house in Bread-street, belonging to the Corporation, so that no fresh building would be required.

South Wales.—Although in the North of England electricity has been extensively used in collieries and engineering works for a number of years, South Wales has until quite recently been without any large undertakings of this class. Several large installations are, however, now being carried out by Messrs. Ernest Scott and Mountain, of Newcastle-on-Tyne, amongst which that of the Tredegar Iron and Coal Company's installation is one of the largest, and consists of five sets of engines and multiphase generators, each of 400 b.h.p., which will be used for supplying electricity to 13 sets of haulage gear and 14 sets of pumps placed underground at Pochin, Bedwellty, and Ty Trist pits in the Sirhowy Valley. The current will be taken by overhead lines from one pit to the other at a pressure of 2,000 volts. Another interesting installation is the pumping plant for the Ocean Coal Company at their Treharris Deep Navigation Pit, Treharris. This plant consists of a 350-b.h.p. engine and generator. The current will be taken down the shaft through heavily armoured cables to the pump, which is placed at the 450-yard level. Besides the above, the same firm have in hand pumping plant for Messrs. North's Navigation Company, Messrs. the Glyn Coal Company, and what is believed to be the first electrical coal-cutting plant in South Wales for the Deiwen Merthyr Colliery, Limited, Quaker's Yard.

Cardiff.—Mr. Arthur Ellis last week reported that for the year just ended the revenue of the electricity department had gone up from £11,153 to £15,515. In addition to the cost of working (£8,255) the committee have paid off £5,692 interest and principal on the loan and still had a surplus of £1,106. If the committee had been a private company, free from the necessity of paying off capital, there would have been £6,798 to divide. The maximum load at the station has advanced from 729 kw. to 951 kw.; the load factor has gone up from 10·78 to 12·31; the number of lamps connected from 37,500 to 51,800; and the number of units sold from 688,000 to over a million. The electric station now ranks as one of the big stations of the country. The total revenue works out at 3·85d. for private supply, which is remarkably low. The Cardiff station is now fifth on the list in the country for the percentage of units sold to those generated. The demand is still vigorous, and it will be necessary to extend the high and low pressure mains in Cathedral-road for 2,505 yards at a cost of £529. There are already 611 applications on that route to help to defray the cost. An extension will also be required in the docks district from James-street to the sailors' hospital. For the month of May the works cost amounted to 1·28d. per unit, or including repayment of capital and interest, to 3¼d. per unit, which is a very fair average. The suggested extension has been approved by committee.

Kensington.—The Council have agreed to notices and plans relative to proposed extensions of their mains in the borough from the Kensington and Knightsbridge Electric Lighting Company (Pelham-street), and from the Brompton and Kensington Electricity Supply Company (Cromwell-crescent and Westgate-terrace); also an application from the National Telephone Company for permission to lay a branch main in Thurloe-square from Pelham-street to the south side of the square. The lighting engineer has been in communication with the city engineer of Westminster as to the lighting of the north side of Brompton-road, east of Montpelier-street, with electric arc lamps, and has ascertained that an order has been given by the Westminster City Council to Crompton and Co. to erect four lamps of the same pattern as those erected by this Council on the south side of the road. The Westminster city authorities have since written pointing out that under the electric lighting contract in their city the trimming and general maintenance is included, stating that they are unable to make arrangements for the necessary attendance to four isolated lamps, and asking this Council to undertake the maintenance of the lamps in question, the charge for current being paid direct by the Westminster city authorities to the Kensington and Knightsbridge Electric Lighting Company. The Council have offered to undertake the lighting, extinguishing, cleaning, and trimming of the lamps in question for the sum of £5 per lamp per annum, it being understood that the price will not include repairs.

Rochdale.—In the six months from October, 1900, to March, 1901, there were 63 applications for current and 57 consumers connected. In the year 1901-2 the numbers were: applications 91, connections 91. The last report contains the following items: "In the past year, though under normal conditions it has been possible to continue the supply from the accumulators during the morning in fair weather, the increase of load has made it essential for the plant to be ready for running at any moment should it become at all dull. This, together with the necessity for supplying motive power on some nights, has made stand-by charges heavy, and required certain increases of staff, which would need only small addition to enable the plant to run continuously throughout the 24 hours. It is, however, satisfactory to note that the Sunday consumption shows an improvement, and it is to be hoped that places of worship may take a supply for both lighting and motor purposes. Owing to the demand during the summer of 1901 being almost wholly for lighting purposes, the output was very small when compared with that of the winter—as to both quantity and maximum. This was naturally a very considerable item to be counter-balanced by the winter output, and makes it unfair to compare the two periods in separate years. It is to be hoped that the small demand for power may prove of assistance during the coming summer, and that the tramway supply will help the undertaking. With the commencement of this financial year the prices were reduced for lighting to 6d. and 2d. on the maximum demand system, or a uniform rate of 4½d., and for power to 2d., varying with the quantity consumed to 1½d. Naturally these charges have had a considerable effect upon the income, but it is practically certain that had these reductions not been made few, if any, consumers would have been connected, and it is very possible that some of those already connected would have discontinued the use of electricity. The applications for power may also be considered the result of the adoption of a more suitable charge."

Stafford.—With regard to the transplantation of Messrs. Siemens's works from Woolwich to Stafford, and to the enormous difference which the consequent addition of some 10,000 inhabitants is expected to make to the old borough, the *Midland Express* says it must not be supposed, however, that these well-known Government contractors are the pioneers of the engineering industry in Stafford. It is only necessary to mention here three eminent firms which for a number of years have carried on this trade with ever-increasing success, and upon which is dependent about one-tenth of the population. Messrs. W. G. Bagnall and Co., Limited, are world-famed engine builders and light railway constructors, important contracts having been carried out by them in all parts of the globe. Messrs. W. H. Dorman and Co., Limited, whose extensive works are in the north end, find occupation for some 200 workmen, and are always busy. Messrs. W. O. Hooper and Co., Limited, are old and well-known electrical engineers. They are at present engaged with large contracts for Sheffield manufacturers, and are in a very flourishing state. Nevertheless, the advent of Messrs. Siemens marks a new era in the commercial history of the town, and if, as some think, the shoe trade should soon prove to be in a moribund condition, engineering will be quite ready to take its place and constitute itself the staple trade of the district. There is no reason why some time in the not far distant future Stafford should not become a seat of industry as important in its way as the two great manufacturing districts of the North and South. It is conveniently situated on the main line of a great railway system, provides a terminus for branch lines of two others, and is also within easy reach of the North Staffordshire and Cannock Chase coalfields. Moreover, labour and land alike are comparatively cheap. Messrs. Siemens may not be the only firm to realise and take advantage of these facilities, and meanwhile Stafford will do well to prepare herself for future contingencies, so that when she is tried she may not be found wanting. A few good builders, with plenty of enterprise and plenty of capital, are badly needed. Now is an excellent time for them to come forward.

Poole.—We understand that a committee of the Town Council are considering the following proposal by the Bournemouth and Poole Electricity Supply Company with regard to electric lighting of streets from the quay, along High-street, Parkstone-road, to Bourne Valley North-road, part of St. Peter's-road, and View-road, Parkstone. The method of lighting proposed is partly by arc lamps of 2,000 nominal candle-power erected in special standards, and partly by incandescent lamps installed in the existing gas lanterns. The charge for current supplied to be for each arc lamp, inclusive of attendance, cleaning, renewal of carbons, lighted from dusk to midnight, £15. 5s. per annum. The charge suggested for current supplied to each incandescent lamp of 25 c.p., installed in the existing gas lanterns, inclusive of attendance, cleaning, and renewal of lamps, lighted from dusk to midnight is £2. 7s. 6d. per annum; or if lighted throughout the night the sum of £3. 12s. per annum. For 32-c.p. lamps the charge would be the sum of £2. 16s. 6d. per annum until midnight, of £4. 7s. 6d. per annum for all-night lighting. The Corporation would have to undertake the provision of the lamp-posts, lamps, and lanterns, etc., the estimated cost of which would be £25 per lamp. The Corporation would also have to pay for the conversion of the existing gas lanterns at an estimated cost of £1. 10s. each. In addition, there would be the cost of switchgear and connections to the main at an estimated cost of £2. 18s. each. The company propose to carry out the above at cost price, charging the Corporation a moiety of that total over a period of three years, under the terms of a purchase-hire system, or the cost might be paid outright if preferred. If the Council preferred to pay for current by meter, the charge proposed is 2½d. per unit net, the Council paying cost of installation and conversion. If after 12 months the contract be renewed for three years, the company would bear one-half the cost of switchgear and connecting the lamps to the main—viz., £1. 9s. per lamp—and if renewed for five years the whole of the cost or £2. 18s. per lamp. The above estimate makes no provision for moonlight nights, when all the lights would not be required, and for which allowance could be made.

Tunbridge Wells.—The Town Council have decided to apply for an additional £10,000 loan, owing to the rapid strides the electrical undertaking is making. During the debate it was stated that the committee were amply providing for the upkeep out of revenue in addition to their reserve fund on the capital account. The plant was now in better order than it was the first year. The best argument the speaker could use was that he could get a customer for the undertaking for £100,000, which had cost £60,000. The telephone undertaking also was worth more than it cost. On Friday the members of the Electric Lighting Committee paid an official visit to the generating station to inspect the extension works which the contractor had just completed. The chairman of the committee (Mr. Elvy Robb) and the engineer (Mr. Horace Boot) received the visitors. In six years these works have trebled in capacity, and, large as they are now, it is estimated that at the present rate of progress the limits of the present extension will be reached in three years, and a further enlargement will then be necessary. The works are already larger than those of Hastings, Eastbourne, Dover, or, it is said, of any neighbouring town except Brighton. There are now at the works six engines aggregating

Digitized by Google

a total horse-power of nearly 3,000, together with five water-tube type and two Lancashire boilers. The station now has its own siding, so that the coal is only handled once from the pit's mouth. In the present building space is provided for two additional 18-h.p. boilers. The new cooling tower is of large proportions, and is capable of dealing with some 90,000 gallons of water per hour. The condensing plant is also particularly interesting. About 64 miles of distributing cable are now in use. The prevention of smoke nuisance is costing the undertaking £1,000 annually of its possible profits, so that this is a severe loss to the ratepayers. As the accounts published in another column show, the number of units generated during the past year shows a further substantial increase—viz., 800,160 as against 702,574 the preceding year. The number of lamps has gone up from 35,260 to 43,370, an increase of upwards of 8,000 lamps. The income of the undertaking is now no less than £11,200 per annum, or an increase of nearly £2,000 on the past year. The gross profit has also increased by £1,600. This profit has been obtained by selling electric energy at an average price of slightly over 4½d. per unit for private lighting and the low price of 1½d. per unit for public lighting. The net profit carried forward this year brings the surplus to £1,985, besides which £7,000 has been paid off the capital, and votes to the extent of 3d. in the £ made in relief of the general district rate.

South Africa.—We are indebted to the *British and South African Export Gazette* for the following items: The plans and specifications, upon which tenders for lighting Ladysmith with electricity can be called are in course of draughting, and electrical contractors are consequently in presence of an opportunity for securing the undertaking. A site for the generating station near the railway station coal-yard has been chosen. It is expected that the installation should be turned out of hand complete within 10 months. The watering of the locomotives in the dry season on the Natal Government railway system has hitherto been a serious problem. In the course of the past year, however, a new departure has been made in the cases of five stations on the main line, and the innovation will probably receive wider application. Instead of transporting the water in pipes along the line from distant sources of supply, electric pumping installations have been set up and water drawn directly from neighbouring rivers or dams. At Hill Crest, for instance, the water is drawn from the Umhlatuzi River, whereas formerly it had to be run from Pinetown Bridge, or even from Durban, 11 and 28 miles distant respectively. At Inchanga the pumping plant is combined with the electric lighting plant in one house and the water drawn from a dam. A new cement tank to hold 100,000 gallons, a part of the scheme, is now in course of erection on a neighbouring hill. At Cato Ridge the water is pumped from a drainage collecting dam and transported three miles in pipes to the railway. At Thornville Junction the water is drawn from the neighbouring Umlaas River, instead of, as formerly, run from Maritzburg, 11 miles distant. The Umsindusi River has also been drawn upon, at considerable cost, to supply the Maritzburg station, three miles distant, owing to the inability of the Corporation of the latter city to furnish the necessary supplies. Whether by way of advice or stimulation, the Assistant Secretary of the Transvaal Administration recently submitted a number of points for the consideration of the Town Council. The first invited the consideration and recommendation of the Council on and anent the charges levied for Government, municipal, or private lighting, furnished by concession or contract; the second requested the Council's opinion on the advisability or otherwise of granting to the Council legal authority to acquire, construct, and work a central power station with the necessary connections for the supply of electricity for lighting purposes; the third asked the Council's views on the advisability or otherwise of utilising such central power station for the supply of electricity for other municipal purposes, such as tramways, etc.; and the last tended to elicit the suggestions of the Council on the means by which it would meet the charges incurred by the several schemes. The Council have considered these matters in committee, and resolved to bring them before a subsequent meeting, but their final decision has not yet been announced. The scheme submitted by Mr. P. Herd, Durban, for lighting Newcastle (Natal) with electricity has been accepted by the Town Council. The concession is for 10 years fixed, after which date the Council is to have the right to continue the agreement, or acquire the outside installation at a fair valuation, the generating station and equipment being handed over to the Municipality free of charge. The projected service will be of a capacity of 1,600 16-c.p. incandescent lamps, and the concession includes the right to supply power. The current will be supplied to the consumers by meter.

PROVISIONAL PATENTS, 1902.

MAY 29.

12218. Improvements in or relating to electric ignition mechanism for internal-combustion motors. John James Henry Sturmey, 18, Hertford-street, Coventry. (Charles Edgar Duryea, United States.)

12231. Improvements in brushes for dynamos and motors. John Aspden and George Aspden, Penny Bank-chambers, Halifax.

12237. Circuit breaker with spark destroyer through an air current forcing its way into a vacuum. Richard Theodor Quaas, Willoughby, Westby-road, Boscombe.

12241. Improvements in or relating to electric arc lamps. Hugo Bremer, Westinghouse-building, Norfolk-street, Strand, London.

12262. Improvements in or relating to permanent ways of electric and other railways. Harry Pace, 21, Constantine-road, Hampstead, London.

12284. Improvements in light accumulators for continuous and alternating currents. August Engelsmann, 111, Hatton-garden, London. (Complete specification.)

12290. Improvements in pressure-regulating apparatus for electric mains. Charles Turnbull, jun., 70, Chancery-lane, London.

12291. Improvements relating to electric switches. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12292. Improvements in electrical cut-outs or fuses. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12293. Improvements relating to electric fuse boxes. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12294. Improvements in dynamo-electric machinery. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12301. Improvements relating to electric motor road vehicles. Adolph Pollak, 45, Southampton-buildings, Chancery-lane, London.

12309. An improved electric heating device. Frederic de Mare, 1, Queen Victoria-street, London.

12316. Improvements relating to electric railways and tramways. Jasper Wetter, 37, Essex-street, Strand, London. (A. Sengel, Germany.)

MAY 31.

12329. Improvements in instruments for measuring electric currents and minute mechanical strains or movements. Louis Rottenburg and Paterson, Cooper, and Co., Limited, 62, St. Vincent-street, Glasgow.

12330. Electric motor-starting switch. Louis Rottenburg and Paterson, Cooper, and Co., Limited, 62, St. Vincent-street, Glasgow.

12340. Electrical water-gauge indicator for steam-boilers or water-tanks. George Hunter Robinson, 31, Spring-road, Portswood, Southampton.

12343. Improvements in electric signals. Alfred Charles Brown, 7, Queen's-square, Finsbury-avenue, London.

12351. Improvements in or connected with apparatus for telegraphing or signalling through space. Anthony Bernard Tubini, 173, Fleet-street, London.

12386. Improvements in electric generators and motors. John Cook Stewart, 62, Vincent-street, Glasgow.

12390. The zinc-dust secondary cell. David Leonard Chapman, 10, Parsonage-road, Withington, Manchester.

12415. Improvements in regulators for alternating electric current circuits. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles P. Steinmetz, United States.)

12416. Improvements in tubulating machines for incandescent electric lamps. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (William R. Burrows, United States.)

12438. Improvements in induction coils. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske A.-G., Germany.) (Complete specification.)

12439. Improvements in or relating to electric safety devices for railways and the like. Carl Peter Johansen, 111, Hatton-garden, London.

12449. Improvements in means for registering, or metering, electrical energy, to be charged for under varying conditions of supply. Leonard James Aron, 47, Lincoln's-inn-fields, London.

12463. Improvements relating to electrical measuring instruments. Edward Weston and Adelbert Oswald Benecke, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12469. Improvements relating to electrical indicating and recording instruments. Edward Weston and Adelbert Oswald Benecke, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12474. Improvements in wireless telegraphic systems. Harry Shoemaker, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12476. Improvements relating to electric recording apparatus chiefly designed for use in connection with electric measuring instruments. Edward Weston and Adelbert Oswald Benecke, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12481. Improvements in electricity maximum demand indicators. Guy Carey Fricker and George Hinde Nisbett, 46, Lincoln's-inn-fields, London.

JUNE 2.

12483. Means for operating electrically the signals on electric railways and tramways. Joseph Patrick Tierney and John Malone, 44, Booterstown-avenue, co. Dublin.

12494. An improved safety guard for electric tramcars and the like, or similarly propelled vehicles. Robinson Scalin Burn, 6, Finkle-street, Stockton-on-Tees.

12517. Improvements in multiplex telegraphy. George Lewis Hogan, 27, Chancery-lane, London.

12536. Improvements in connection with electric tramcars. Joseph Black and Thomas Hogg, 23, Coleman-street, London. (Complete specification.)

12547. Improvements in making electrolytic baths. Fritz von Liebermann, 321, High Holborn, London. (Complete specification.)

12554. Improved means and apparatus for telephonic communication. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.) (Complete specification.)

12556. Improvements in thermo-electric batteries. Heinrich Kiefer, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

12570. Improvements in and relating to telephonic instruments. Isidore Bernard Birnbaum, 322, High Holborn, London. (Complete specification.)

12573. Improvements in electrolytic circuit breakers. Friedrich Dessauer, 6, Lord-street, Liverpool.

12578. Improvements in current-reversing mechanism for oscillating electricity meters. Philip Middleton Justice, 55, Chancery-lane, London. (Theiler and Co., Switzerland, and Paul Eibig, Germany.) (Complete specification.)

12581. Improvements in electric traction apparatus. Alfred Zehden, 46, Lincoln's-inn-fields, London. (Complete specification.)

12582. An improved system of electric lighting. William Lloyd Wise, 46, Lincoln's-inn-fields London. (The Moore Electrical Company, United States.) (Complete specification.)

JUNE 3.

12604. Automatic telegraphic field transmitter. Percy L. Robertson, 18, St. Swithin's-lane, London.

12607. Improvements in or relating to electric tramcars and the like. William George Inglefield and Herbert Gilbert Hackett, 55, Market-street, Manchester.

12624. Improvements in dynamo-electric machines and motors. Wilfred Robert Vernet Marshall, 121, West George-street, Glasgow.

12671. Improvements relating to telephone systems. Charles Goodwin Burke, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12684. Improvements in preventing leakage of current to studs in surface-contact systems of electric traction. William Griffiths and Benjamin Harry Bedell, 4, South-street, Finsbury, London.

12688. Improvements in or relating to polyphase-current transformers. William Phillips Thompson, 322, High Holborn, London. (Berliner Maschinenbau-Actien-Gesellschaft vormals L. Schwartzkopff, Germany.) (Complete specification.)

12689. Improvements in and relating to combinations of electric switches and wall-plugs. Albert Vandam, 322, High Holborn, London.

12691. An improved process for the electrolytic decomposition of alkaline chlorides and apparatus therefor. Hermann Cuénod and Charles Fournier, 6, Lord-street, Liverpool.

12694. Improvements in or relating to coils for dynamo-electric machines. Ludwig Lohner and Ferdinand Porsche, 111, Hatton-garden, London.

12697. Improvements in perforators for use in connection with automatic telegraph transmitters. Alexander Muirhead, 323, High Holborn, London.

12700. Improvements relating to the manufacture of active material for the plates of electric accumulators. Sigmund Adolf Rosenthal, 27, Chancery-lane, London.

12702. Improvements in the electrical production of iron alloys with the simultaneous production of alkaline oxides and alkaline earths. Gustave Gin, 1, Queen Victoria-street, London.

12706. Improvements in wireless telegraph systems. Cornelius D. Ehret, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JUNE 4.

12733. Electric door contact. Frank Edward Linnett, 137, Kettering-road, Northampton.

12737. Improvements in or relating to blowing-off machines for electric lamp bulbs. Alfred Swan, 50, Wellington-street, Leeds. (Complete specification.)

12738. Improvements in or relating to means or apparatus for effecting an all glass seal between the stem which carries the filament of an incandescent electric lamp and the enclosing bulb. Alfred Swan, 50, Wellington-street, Leeds. (Complete specification.)

12739. Improvements in or relating to bases for incandescent electric lamps, and in means or apparatus for manufacturing the same. Alfred Swan, 50, Wellington-street, Leeds. (Complete specification.)

12749. An improvement in electrical communications for railways and other purposes. Charles Mark Antonio Culverhouse and Frederick Victor Culverhouse, 634, Barking-road, Plaistow, Essex. (Complete specification.)

12752. Improvements in testing the insulation of electric cables. Ernest Alexander Claremont and Charles James Beaver, 4, Bloomsbury-square, London.

12755. Method for reducing or entirely suppressing synchronising currents of single or multiphase alternators working in parallel. Emil Kolben, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12764. Improvements relating to brush-holders for dynamo-electric machines and similar apparatus. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12765. Improvements in and relating to the distribution of electricity. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12766. Improvements relating to apparatus for cleaning electric lamp filaments. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12767. Improvements relating to the control of electric motors. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12780. Improvements relating to telephone installations. Paul Hardegen, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

1782. Improvements in apparatus for rope haulage for lifts, mines, and the like. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.) (Complete specification.)

12783. An improvement in electromagnetic detents. Siemens Bros. and Co., Limited, and Alexander Siemens, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

12793. Improvements in the electrolytic refining of copper. The Metals Corporation, Limited, and Sherard Cowper-Coles, 70, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published June 28.

1901.

11315. Regulators for electric motors. Mackay and Sclater.

11545. Safety devices for automatically disconnecting the current supply to trolley wires used for electric traction. Heyes and Heyes.

12469. Current transformer for telephones. Berthelon.

13239. Alternating-current motors. Wüst-Kunz.

14825. Electrometallurgical treatment of zinc ores and especially blend. Tossizza.

15691. Electric railways on a road contact system. Betts. (Betts.)

17711. Transmission of telegraphic and telephonic signals. Maiche. (Date applied for under International Convention, Feb. 19, 1901.)

19811. Apparatus for testing the insulating of electric cables and the like. Claremont.

24816. Electric railways. Kintner. (Date applied for under International Convention, May 6, 1901.)

25270. Electrically-operated valves and gas-lighters. Baader and Rau.

25710. Electric ignition devices applicable to motor bicycles and to motors generally. Bailly.

26754. Apparatus for use in charging storage batteries. Stover and Suren.

1902.

382. Galvanic cells. Friese.

2816. Electric battery. Allison. (Banks.)

3024. Electric traction by the surface-contact system. Cruvellier.

3533. Winding and circuit-closing devices for electrically-wound clocks. Crook.

5104. Arc lamps and electrodes therefor. Soc. G. et P. de Mestral. (Date applied for under International Convention, Sept. 4, 1901.)

7062. Overhead trolleys for electric vehicles. Häller and Noiset.

8486. Means for operating the carriages, and controlling mechanism of same, of electric telegraphic and similar printing machines. Justice. (Rowland Telegraphic Company.)

8643. Means for damping the oscillations of shafts carrying the hands or pointers of electrical measuring instruments or the like. Nalder and Nalder Bros. and Thompson, Limited.

8809. Electric circuit controllers. Ghegan and Griswold.

9380. Fuse head for electric blasting. Render.

9720. Automatic electric fire-alarms. Offenbroich and Mafell.

9789. Electric railway systems, and more particularly to crossings and switches for the same. Keeler.

MISCELLANEOUS.

The following traffic returns are also reported:

Anglo-Argentine, £539 decrease.
Barcelona Ensanche y Gracia, £120 decrease. Barcelona £99 increase.
Brisbane, £431 increase (month of May, £10,832; decrease, £573).
Buenos Ayres and Belgrano Electric (month of May, receipts £12,454; increase £322), £218 decrease.
Calcutta, £246 increase.
Cape Town (month of May), receipts, £16,330; expenditure, £7,205.
Isle of Thanet Electric, £43 decrease
Mexico Electric (month of May), receipts, £20,380; expenditure, £11,400.
Perth Electric, £168 increase.
Port Elizabeth (month of May), receipts, £3,796; expenditure, £1,872.

NOTES.

Institution of Electrical Engineers.—According to arrangement, the annual conversazione of the Institution will be held on Tuesday evening next at the Natural History Museum, Cromwell-road, S.W. An exceptionally large gathering is expected in view of the general invitation issued to members of the Tramways and Light Railways Congress, in London at the time, to attend the function.

Power Transmission in Canada.—We understand that the Shawinigan Power Company will shortly construct a 50,000-volt transmission line to Montreal, Canada, a distance of 90 miles from the generating station. The plans involve the transmission of 20,000 h.p. to that city, beginning with 4,000 h.p., to which additions will subsequently be made in 4,000-h.p. units. The cables for the line will be of aluminium, manufactured from the ore at Shawinigan Falls.

Glasgow Local Section.—At the annual general meeting of the above section of the Institution of Electrical Engineers, the suggestion was made that as the members would not be seeing each other very often in the course of the summer, it would be a good thing if one or two visits could be made to places of interest in the neighbourhood of Glasgow, such as the new electricity works of the Corporation at Port Dundas and Pinkston. It is probable that arrangements will be made in accordance with this proposal.

Telegraphs in Argentina.—The British Consul in the Argentine Republic, in the course of a report to the Home Department, mentions that there are 24,480 miles of telegraph line in the republic, of which 11,400 miles are owned by the Argentine Government. The gross revenue from the Government telegraphs in 1899-1—last year of which record has been published — was about £100,000. The telegraph system in Argentina is yet far from complete, but it is being steadily extended to reach the outlying portions of the republic.

Wireless Telegraphy on the Congo.—Some little time ago we mentioned in these columns that it was intended to establish a system of wireless telegraphy on the River Congo, in South Africa, as a result of experiments carried out in this country at Withernsea. We learn that fairly good progress has been made with the installation, but that the work has been greatly delayed by the loss of the vessel which was taking out some of the apparatus to South Africa. While awaiting the arrival of more material, however, the mast at Banana has been fixed, and it is hoped to have the service in operation very soon.

Ganz Motors in America. — We understand that an important combination has just been effected between Messrs. Ganz and Co. and what is called the Whitney-Elkins-Ryan-Dolan syndicate for the manufacture of the Ganz motors in the States. The syndicate mentioned recently purchased the Stanley Electric Manufacturing Company's plant near Pittsfield, Mass., and the intention now is to equip the works with plant suitable for turning out Ganz motors on a large scale. It is expected that when the extensions of the Stanley plant have been completed, the company will control one of the largest electrical manufacturing concerns in America.

Apparatus for Heating by Electricity.—Mr. A. Guntz has recently described a method of fitting up apparatus for heating tubes, crucibles, etc., by means of electricity, the heat being obtained, as in other cases, by passing a current through a thin platinum wire. The improvement, however, is introduced of employing a mixture of magnesia and alumina for embedding the platinum wire in the place of asbestos or fusible enamel, which possess the drawback that they alter the platinum wire when the temperature is raised to 1,200deg. or 1,300deg Particulars are given as to the management of such a heating arrangement and of the current which may be used with it, and the author states that he finds this apparatus more economical than gas.

Patent Law in Spain.—We understand that a new Act for the protection of industrial property, including patents and trade marks, in Spain has recently been passed, and came into operation on the 7th inst. Under the new law, so far as relates to patents, very important alterations have been made. The working conditions of patents have been very greatly modified, and a period for compulsory working has been extended to three years. In addition, the time for payment of taxes has been extended under a fine, while at the same time it is provided that inventors paying up their taxes in advance obtain discount on the same ranging from 5 to 20 per cent. It is also provided that applicants who have made prior applications in other foreign countries for patents must make application in Spain within 12 months, failing which any patent granted will be limited to five years.

Electric Furnaces.—In electric furnaces, the bar which supports the pendant electrode serves also to transmit the current. For furnaces of moderate size this is simple and convenient, but for the heavy currents of the present-day installations it is at least open to question whether two functions are properly discharged by a single element. The size of the support is governed by its strength, that of the lead by its conductivity, and both support and lead are limited in size by their capacity for conveying heat from the furnace. A system of connections noted by Mr. C. P. Townsend in the *Electrical World* for June 7 employs a conductor and a separate supporting yoke, each of the minimum size to permit a proper performance of its functions, and each provided with a circulating system for water. Other features of the furnace are a vertical discharge slit between water-cooled walls and a water-cooled fore-hearth—both adaptations from ordinary metallurgical practice.

Chicago Motorcar Regulations.—It is instructive to compare the stringent precautions the municipal authorities of Chicago are taking to protect their city from the motorcar invasion with those that obtain in this country. We doubt, however, very much whether it will be found possible to enforce the same. In effect it is proclaimed that no electric, steam, or other mechanically-propelled vehicle, while standing in any park or on any boulevard, street, or drive, shall have any of the machinery or generating plant in operation. Further, no person shall cause or permit any such vehicle to emit smoke, vapour, or offensive odours while in any park or on any of the boulevards, and no bell or gong is to be rung or other mechanical alarm given by any occupant of an automobile. A regulation limiting the speed of motorcars to eight miles an hour is also made. Under these conditions it is obvious that it is far easier, if at all, to keep within the law with an electric vehicle than with an automobile driven by steam or petrol.

The Paris Underground Electric.—The managers of the Paris metropolitan electric railways have found out that there is a limit above which it is impossible to compress even the most patient of railway passengers. Whether this is above or below the 16-to-one-compartment standard of our Underground, we cannot say from actual experience, but the fact exists that on the Paris line train after train arrives at the stations without being able to

Digitized by Google

take up any of the passengers waiting. At the beginning of operations the trains consisted of four carriages, with accommodation for 50 passengers each. Latterly, during the busy hours of the day, trains composed of seven carriages, capable of holding 50-55 passengers each, have been run. Last week the police issued a temporary license allowing, as an experiment, the use of longer trains. The trains will be composed of eight carriages, the first and last of which will be fitted with two 140-h.p. motors, the whole of which will be under control of the driver at the head of the train

Wireless Telegraphy.—Mr. Marconi's new wireless telegraph station at Tablehead, Cape Breton, has, according to a Halifax message, now been completed, and the apparatus installed for the proposed Transatlantic service. The feature of the installation is the signal towers, which are 215ft. high. It had been arranged, if possible, to send a message from the new American station to the King on the occasion of his Majesty's Coronation, but it is feared that time is too short to permit of this arrangement being carried out. An interesting sidelight on wireless telegraphy is the unfinished chess match which took place in mid-ocean between passengers on the "Campania" and the "Philadelphia." The two vessels were separated at the time by a distance of about 70 miles, and the different moves of the rival players were indicated by means of Mr. Marconi's system The game was suspended for dinner. Then the "Lucania" interrupted the matter for a business talk with the "Campania," and the ships were unable later to get into communication again.

Separation of Metals. — Dr. N. S. Keith has described before the American Electro-chemical Society a striking method for the treatment of metallic solutions with insoluble anodes. In work of this character the concentration of the cations constantly decreases, and in order to secure a uniform regular deposit the current density must be correspondingly reduced. This is usually accomplished by controlling the current through the vat, a very uneconomical expedient. Dr. Keith's solution consists in circulating the electrolyte through a number of vats in series, the electrodes therein being connected in multiple and the number of plates increasing in successive numbers of the series. As the same current passes through each vat, it is obvious that the electrolyte is subjected to a current of diminishing density, and that if the strength of the incoming electrolyte be maintained constant, and the numbers of electrodes in successive vats properly proportioned, a regular deposit may be obtained throughout the series, and the full capacity of the generator used.

Mr. Edison's Storage Battery.—Several of the American technical journals received by the last mail publish particulars of the recent tests of Mr. Edison's latest form of storage battery, of which glowing accounts have been sent over here by the enterprising correspondents of the daily Press. The particulars referred to, however, are given in our contemporaries on the authority of Mr. Edison himself, and may, therefore, be assumed to be authentic. The first test, we gather, was made on a runabout machine carrying two passengers, and equipped with 21 cells, the complete equipment of batteries, including the electrolyte, weighing 332lb. The route selected was over the ordinary roads about New York, and in all 75 hills were ascended, varying from 2 to 12 per cent. grades. On the outward journey the automobile travelled 62 miles, and when it was brought back 83 per cent. of the original speed could still be had from the batteries. On another occasion over a fairly level road the car was run to a standstill. It travelled 85 miles, and stopped when the battery showed only 6·3 volts. The initial pressure from the 21 cells was 29 volts. Mr. Edison is now reported to have completed a 5,000-mile endurance test, and intends shortly to put his new battery on the market commercially. As far as distance travelled on one charge, the above figures do not come up to records for ordinary accumulators.

The Velocity of Light.—This important subject was recently dealt with by Mr. Michelson in a paper before the American Physical Society, an abstract of which is given in the current number of the society's *Bulletin*. The author shows that by purely optical methods the observed velocity of light and the observed sidereal aberration constant give a solar parallax of 8,808 seconds, with a probable error of less than one-thousandth. The optical method of measuring the sun's distance he regards as inherently more trustworthy and far less expensive than the astronomical methods. The highest development of the optical method calls then for as accurate a knowledge of the velocity of light as can be experimentally observed, and in this direction one has the aid of three converging sets of experimental methods—namely, those of electromagnetic measurements of the light-speed ration (r), those of invisible Hertzian waves, and those of visible light waves. Quoting from the report of the 1900 International Physical Congress as giving 300,010 km. per second for the best result with r, and 299,130 km. per second for Hertzian-wave measurements, he inclines to 299,890 km. $\pm$ 60 km. for the best result with optical measurements. Finally, a new method of optical measurement is outlined, using a revolving mirror making 250 turns per second. It is hoped that with this method the speed of light may be measured to within 5 km. per second or less.

A New Atlantic Cable.—We understand that an agreement has been arrived at between the German Post Office and the German Atlantic Telegraph Company for the construction of a second cable from Borkum to the Azores and New York. Experience has shown that a safe and uninterrupted service between Germany and America cannot permanently be maintained with one cable, and the Imperial postal authorities therefore urged the necessity of a second cable being laid between the two countries. The new line is to be set in operation by Jan. 1, 1905. The convention between the parties extends the period of the company's concession to Dec. 31, 1944, and carries with it a Government subsidy of £85,500 per annum for the use of the two cables. The company on their part undertake to pay the Government 1·92d. per word in the case of each message paid for at the ordinary rate of 1s. per word, and after deducting this charge the remainder of the receipts up to as many as 3,750,000 words goes to the company, who have to meet the other taxes and expenditure out of the amount. When the number of words in the paid messages exceeds 3,750,000, the Government will receive in addition to the tax of 1·92d. a further tax of 6d. per word up to 7,170,000 words, but the 6d. tax will not apply in case of any further increase in the number of words beyond that total. The contract for the supply and laying of the new cable, which is estimated to cost £1,050,000, has been placed with the North Sea Cable Works Company, of Nordenham.

Conductivity of Solutions of Mixed Electrolytes. Mr. Hans Wolf, in a paper published in Germany and abstracted in the Chemical Society's *Journal*, states that the conductivity of a mixture of two electrolytes differs from the sum of the conductivities of the electrolytes singly on account of (1) the change of viscosity of the solution; (2) decreased dissociation, due to replacement of water by the other electrolyte; (3) chemical reaction

Digitized by Google

between the electrolytes. For solutions containing a small quantity of potassium chloride or sodium bromide and variable quantities of acetic acid or alcohol, the first action is alone of importance; with stronger solutions (0·5 normal), the second comes into play. When chloro-acetic acid is used in place of acetic acid, the matter is further complicated by the occurrence of the chemical reaction to an appreciable extent. The conductivity of zinc sulphate is diminished to a greater extent by acetic acid or alcohol than is that of potassium chloride. Tartaric acid has an effect similar to that of acetic acid, except in the case of zinc sulphate, the conductivity of which is but little affected. This is doubtless due to the formation of hydrogen ions in place of zinc ions, which increase the conductivity almost as much as it is diminished by the increased viscosity. Mixtures of the salts of fatty acids with fatty acids were also examined; in these cases, the chemical change can be calculated and allowed for; the remaining change of conductivity is found to be very similar to that observed in the case of sodium bromide and acetic acid.

Fulham Wiring Rules.—The Metropolitan Borough Council of Fulham have now drawn up a set of regulations for the supply of electrical energy and the wiring of buildings in their district. The Council not undertaking the wiring of houses, the first important provision is to the effect that all work inside houses is to be carried out in accordance with the rules issued by the insurance company with whom the premises are insured. This is an excellent clause, and one which will commend itself to consumers from the point of view that it tends to greatly simplify their responsibility in wiring their own premises. The regulations go on to give a number of useful points, amongst which we notice that no joints are to be made in wires to be buried in casing in walls. Another general provision is that no circuit shall require a current of more than five amperes. With regard to the refusal of the Borough Council to supply to any installation, it is laid down that the Council shall be entitled to exercise this right if when testing with a pressure of 200 volts the insulation resistance of the entire installation shall prove to be less than the total number of ohms which shall be indicated by the number resulting from the division of 20,000,000 by the figure expressing the maximum current in amperes which has been named by the consumer in his application for a supply of electricity. The clauses as to supply for motors are to the effect that when a supply is required for this purpose notice in writing must be given to the engineer, who shall approve in writing of the apparatus and arrangement before it is installed. Motors up to 3 h.p. may be single-phase, but over that horse-power two-phase motors will be required. Starting resistances must be so arranged that the variation between each stop does not exceed three amperes. The other clauses of the regulations are practically in the ordinary form, and do not call for special mention.

The Bow v. the Wheel Trolley.—Discussing European practice in electric traction in the current number of the *Street Railway Journal*, Mr. H. Vellgath says the most notable departure in European practice from American standards is in the use of the bow instead of the trolley wheel. During the last few years the former has grown steadily in favour, although it is not as generally used as the wheel. It is claimed on behalf of the bow trolley that it eliminates all danger of loss of contact, and that there is no necessity for reversing the bow when the direction of the car is changed. Greater contact surface is afforded and much easier spans in curves are secured, which, while improving the appearance of the overhead construction, greatly decrease the cost of maintenance. In order to allow the bow to turn over automatically when the car changes its direction, the distance between the rail and the trolley line ought to be as constant as possible. European engineers who favour this form of construction contend that there is no difficulty in doing this, and even many users of the trolley wheel favour the bow for higher speeds and heavier traffic where heavy currents are used. The writer states that many changes and improvements have been made in the bow in recent years, and in its present form it is favourably considered by the engineers of many systems who, however, adopted the trolley wheel when the bow was not in so efficient a state as it is at the present time. Further discussing European practice, the writer notes that the slotted conduit with complete metallic circuit has been found satisfactory, but it is only used in large cities where the traffic is very dense, where the difference in cost between it and a modern first-class trolley construction is very slight, and where the undertaking may be expected to pay good interest. On the Continent it has only been installed where the trolley has been forbidden. Thus, the system is extensively used in Berlin, Brussels, Paris, and Budapest, and on a smaller scale in a few other cities.

Developments in Electro-Chemistry.—Mr. C. P. Townsend, in the *Electrical World*, describes a distinctly novel electrical method developed by Mr. P. Bary, of Paris, for the distillation of various metals. The invention obtains its novelty from the fact that it depends for the volatilisation of the molten metal upon the spark, or, perhaps, more accurately, the arc which is formed when a stream of molten metal carrying a current is momentarily interrupted. Under the sudden increase of resistance metal is vaporised, and if the operation is carried out in a closed vessel, and in a current of inert or oxidising gas, the products are readily collected. In every form of apparatus described molten lead or tin flows in a thin stream from an upper to a lower vessel, and conducts the current between them. This falling stream is momentarily interrupted, either by a mechanically-operated valve controlling the outflow by a rotating skeleton wheel whose spokes break the column, or by the current itself. Full utilisation of the current requires a more rapid interruption than can be effected by mechanical devices, and Mr. Bary gives as his preferred form the following construction: The molten metal flows from the upper chamber to the hearth through a series of nozzles, perforated and extending over the surface of the pool. Each stream impinges upon a metallic contact in the circuit, and the volatilised products, together with the excess of liquid metal, pass through a tube, the former to the collecting chambers and the latter to what is known as the "trap" beneath the tube. A current of inert or oxidising gas flows through a pipe and then through the lower chamber. This chamber is fitted with a refractory bed and with resistances, the function of the latter being to keep the metal in both chambers in molten condition. The necessary interruption of the flowing stream in this construction depends upon the experimental fact that a film of metal traversed by a current of sufficient density is contracted and broken, to be at once restored, the interruptions occurring at the rate of several hundreds per second.

A 50,000-Volt Transmission Plant.—The distinction of being the first to place in actual commercial service a large plant employing 50,000 volts transmission belongs to the Missouri River Power Company. Mr. W. G. McConnon contributes an admirably illustrated article to the *Electrical World* of the 7th inst., in which he describes at length the principal features of the interesting installa-

Digitized by Google

tion. At the mouth of Black Rock Canyon a dam has been thrown across the River Missouri about 480ft. in length, and designed to give a 30ft. head of water. The canyon by which the water comes to the power house is from 400ft. to 700ft. wide and less than half a mile long. It is interesting to note that in winter, although the lake above freezes over, the water in the canyon does not freeze over, and the flow to the power house is as free from ice in winter as in summer. The power plant consists of 10 750-kw. direct-connected generators, with four exciters, of which two are 90-kw. machines direct-connected to separate wheels, one a 225-kw. machine with a separate wheel, and one a 115-kw. motor-driven generator. Each waterwheel has its own governor. The feature of the installation, however, is the high voltage employed on the lines to Butte. This is 50,000ft. The distance by pole line from Canyon Ferry to the Butte sub-station, where step-down transformers are employed to reduce the voltage to 2,200 volts, is 65 miles. The line starts out at an altitude of about 4,000 volts above sea-level, and gradually rises until it reaches an altitude of 7,300ft., a few miles east of Butte. The line itself consists of two ranges of poles about 50ft. apart. The cables are arranged in an equilateral triangle, with a spacing of 78in. between centres. Each line consists of three seven-strand copper cables, each cable having a cross-section of slightly over 106,000 circular mils. These cables are transposed five times between Canyon Ferry and Butte. The average distance apart of the poles is 110ft. A view and cross-section of the insulator used on the line, with the glass sleeve fitting over the pin below the insulator, is shown in one of the illustrations, and the writer explains that it has been found, after exhaustive tests, that a thoroughly dry oak pin of the length used in this installation, boiled in paraffin, will hold up alone under 50,000 volts. Hence the object of the glass sleeve below the insulator is to keep as great a length as possible of the pin dry under all conditions of weather. Practically the whole of the electrical apparatus in this plant was furnished by the Westinghouse Company, of Pittsburg.

Three-Phase v. Two-Phase for City Distribution. With this title Mr. B. A. Behrend read an important paper before the recent convention of the American National Electric Light Association at Cincinnati, in which he ultimately decides in favour of the three-phase system as having certain slight advantages over the two-phase system for distribution in cities. At first there were a great many advocates of the two-phase current on account of greater simplicity, but looking to-day over the installations of alternating-current systems for city distribution, it is found that the three-phase distribution has been preferred in the majority of plants. The system which will be most favourable for distribution of light and power is that in which the potential on one phase is as little as possible affected by a change on load on another phase This may be considered the criterion by which to form an opinion of the superiority of one system over another. Theoretical considerations, as well as experience, have established the fact that a two-phase machine, so far as independence of phase is concerned, is not superior to a three-phase machine if the load on the latter is properly arranged. The output of a two-phase generator is equal to the output of a three-phase generator. In other words, any two-phase generator may be wound as a three-phase generator without changing the rating, and *vice versâ*. The regulation of both two-phase and three-phase machines being equally good, according to the statements above made, it would seem that the three-phase system was preferable to the two-phase on account of requiring only three wires instead of four, leaving out of consideration the two-phase three-wire system. There is, however, a very interesting fact which should be observed—namely, a three-phase generator on which the load is connected between the outside wires is greatly inferior to a two-phase so far as regulation is concerned. Only, if the neutral connection of the three-phase generator is made use of, and if the load is put on between the neutral and the outside wires, the regulation in the three-phase machine is, in all respects, equal to that of the two-phase machine. But it must be observed that the three-phase machine requires, under these conditions, four wires, as in the case of the two-phase machine. Summing up the *pros* and *cons*, Mr. Behrend considers that there is comparatively little choice between the two-phase and the three-phase systems, but there are certain slight advantages in favour of the three-phase system. If 75 per cent. of the load is a lighting load and 25 per cent. is a load that requires little attention to regulation, as, for instance, an arc light load having its own regulator or a motor load, a three-phase generator has the further advantage that it can be operated as a single-phase machine, the lighting load being connected between two outside wires. In this case, the lighting load can be very easily regulated, while no attention need be paid to arc light or motor load, as that is supposed to take care of itself.

The Double-Trolley System.—It is a question which has for a long time engaged the attention of traction engineers whether under certain conditions the double-trolley system has advantages which would decide in favour of its adoption in preference to the single-wire system as ordinarily applied in America, on the Continent, and in this country. In Sydney, New South Wales, the latter system has been favoured up to the present, but we understand that the State Railway and Tramway Commissioners and their engineers have now definitely decided on a change over from the single to the double trolley system as being more suitable to the requirements of the tramway service in that city. The reasons which have moved the authorities to come to this decision are given in a report by the electrical engineer to the Sydney tramways, Mr. O. W. Brain, M.I.C.E. As most of our readers are doubtless aware, the essential difference between the two systems is that with the single solid wire the current is conducted back to the power station by the track rails, while in the double system it is returned by the second trolley wire, in exactly the same manner as it is supplied from the station by the single wire. In order that the return current should be carried back to the station by the track rails, it is necessary that these should be bonded or continuously electrically connected, this involving heavy expenditure both in capital cost and subsequent maintenance. Herein then lays the principal advantage of the double-trolley over the single-wire system. The experience at Sydney has been that with the greatly increased traffic, and the consequent larger currents which have to be employed, there is considerable danger in returning the current to the station over the track rails. In view of this fact, therefore, and of the still larger increase in the tramway current which it is anticipated will have to be provided for in the near future, it has been finally decided to discontinue the use of the track rails for the purpose mentioned, and to adopt the second trolley wire. It is quite recognised that the maintenance of the overhead wires in good electrical condition will under this system require closer supervision and more attention than the existing one ; but against this it is thought the advantage will be the saving in the fact that the whole of the work involved in the maintenance of the bonding will be entirely done away with. While the expenditure incurred

Digitized by Google

with the double-trolley system has, no doubt, mainly stood in its way in the large cities where tramways are run by private enterprise, in the United States it is satisfactory to learn that the double trolley has been successfully used on systems which are much larger than that of Sydney. In some cases the local authorities have insisted upon its adoption on account of the interests concerned. The best-known instances of this are the cities of Cincinnati and Washington, the overhead systems of which are worked by the overhead trolley, the Congress itself having passed a special Act insisting upon it in the latter case.

Photometric Values of Arc Lamps.—Prof. C. P. Mathews presented his third report on the investigation of the photometric values of arc lamps to the members of the American National Electric Light Association at their recent Cincinnati convention. The first tests made were of five direct-current 6·6-ampere enclosed arc lamps, and the following results were arrived at: With no outer globe and opalescent inner globe, the watts per mean candle-power were respectively 1·07, 1·37, 1·24, 1·27, 1·3, and 1·28. With a clear outer globe and opalescent inner globe, corresponding values of watts per mean hemispherical candle-power were respectively 1·2, 1·29, 1·35, 1·24, 1·38, and 1·37. A conclusion arrived at is that for street-lighting the best distribution is obtained with closed base inner globes. Three 6·6-ampere alternating-current lamps were tested with the following results: with no outer globe and an opalescent inner globe, the watts per mean hemispherical candle-power were 1·86, 2·06, and 1·76; with clear outer and opalescent inner globe, the corresponding quantities were 2·25, 2·06, and 1·55. Three 7·5 ampere alternating-current series enclosed lamps tested gave these results: with no outer globe and an opalescent inner globe, the watts per mean hemispherical candle-power were respectively 2·28, 1·94, and 1·8. These figures show that while the alternating-current lamp taking 6·6 amperes is inferior to the direct-current lamp of the same current capacity in light-producing power below the horizontal, the use of a shade in the former brings down the specific power consumption to within 13 per cent. of that of the direct-current lamp. The mean power factor of the 6·6-ampere alternating-current lamps is ·88, and of the 7·5 lamps ·83. The results of tests of a 450-watt arc under varying conditions show that 450 watts expended between a given number of carbon points may produce widely different values of candle-power in useful directions. These variations depend upon whether the current is direct or alternating, the arc open or enclosed, the globe clear and opalescent, the arc shaded or otherwise, the current large or small. Another conclusion is that no advantage comes from the substitution of the 6·5-ampere arc with clear globe for the 9·5-ampere open arc in so far as distribution of light is concerned. Still another conclusion is that if the open and enclosed arc tested were suspended at the same height, say 25ft., they would produce equal illumination at a suspension of about 117ft. from the lamp, but beyond this distance the enclosed arc would have the advantage over the open as a street illuminant. The superior candle-power distribution of the enclosed arc is clearly and chiefly through the use of the opalescent inner globe. This globes becomes itself highly luminous, thus strengthening the intensities near the horizontal. Tests were also made of high and low grade carbons, the primary object being the determination of the relative candle-power obtainable when the carbons were burned in 9·5-ampere 450-watt open arcs. The high-grade carbons when solid gave more candle-power at each of the three angles of measurement. When, however, they were cored, they fell behind the low-grade carbon throughout one of the angles. This is doubtless due to the deep crater formed in the cored carbon. Although high-grade carbons give superior candle-power they showed somewhat shorter life when burned open, the difference being about 9 per cent. for the positive, but slight for the negative.

Mr. Marconi on Space Telegraphy.—Mr. G. Marconi, happily recovered from a recent attack of influenza, was able to deliver his promised lecture at the Royal Institution last Friday evening on the progress of electric space telegraphy. A typical Royal Institution audience gathered together on this occasion to hear the young inventor explain the apparent mysteries of wireless telegraphy. As Mr. Marconi said, however, in his opening sentences, it is not, after all, wonderful that man should devise a means by which he is enabled to apply electricity to convey messages through space, having regard to the fact that the light and heat waves from the sun travel through millions of miles of space, and sound also reaches the ear without any artificial conductor. In describing the apparatus employed, he remarked that it is now possible to establish a considerable number of wireless telegraph stations simultaneously in the vicinity of each other without the messages suffering any interference. A powerful transmitter giving off waves actuated near one of the receiving stations may, however, prevent the reception of messages to some extent. But the ordinary system of communication by wire and telephone may be subjected to similar interference. For example, it was found impossible at Cape Town, two years ago, to work the cables at certain times when the electric tramways were in operation. Describing the principle of the coherer, Mr. Marconi stated that it is by means of a magnetic detector that he has improved upon the coherer hitherto employed. He has found it to be more sensitive and reliable than the coherer, and it does not require so many precautions in the working. It may be possible, he said, with this system to receive messages at a speed of several hundred words a minute. At present, by the aid of the detector, 30 words a minute can be read. Incidentally, Mr. Marconi mentioned that there are no fewer than 40 land wireless telegraph stations in Great Britain and Europe equipped with his system, and over 40 vessels of the British navy carry similar installations. On two of the White Star Line steamships as much as £60 has been collected for the transmission of messages for passengers on a single trip. A most interesting point to which Mr. Marconi referred towards the end of his lecture is that at distances of over 700 miles the signals transmitted during the day often fail entirely, while those sent at night remain strong up to 1,551 miles, and are even decipherable up to a distance of 2,099 miles. This result may be due to the diselectrification at the very highly charged transmitting elevated conductor operated by the influence of daylight. He did not think, however, that the effect of daylight will be to confine the working of Transatlantic wireless telegraphy to the hours of darkness, as sufficient sending energy can be used during daytime at the transmitting station to make up for the loss of range at the signals. It is probable, however, that had he known of that effect at the time of the Newfoundland experiments, and had tried receiving at night time, the results would have been much better than those actually obtained. In conclusion, Mr. Marconi quoted from a leading article in the *Times* of Dec. 21, 1901, in which it was prophesied that wireless telegraphy would soon become a potent agent in cementing those ties between England and the Colonies, which other recent events have done so much to strengthen or even to create.

THE NEW SHOREDITCH ELECTRICITY WORKS.

On Monday last there was inaugurated the supply from the large new works which the Shoreditch Metropolitan Borough Council have had erected at Whiston-street, Haggerston. The opening ceremony in the afternoon was performed by Councillor H. B. Bird, the chairman of the Lighting Committee, and the same gentleman presided over the dinner which was given by the engineers and contractors at the Great Eastern Hotel in the evening. At both of the functions speeches were made which showed the superabundant energy possessed by the representatives elected to serve on the Shoreditch Borough Council. This energy was displayed in the shape of forcible criticism, and we gather that there is no fear of any undertaking ruled by the Council becoming moribund for want of opposition. We are especially pleased to note, moreover, that however keenly the details of the municipal undertakings at Shoreditch are criticised by councillors in opposition, the progress of these are not retarded in consequence. The opposition to the electric lighting schemes in the past has largely resulted from an incomplete knowledge of the facts of the case.

It was in 1897 that the first Shoreditch electricity works were opened by Lord Kelvin, and at the time the attention of all electrical engineers and municipalities was drawn to the combination of the dust destructor with the electric lighting works. There is no doubt that a few of the local people expected too much from the combination, and statements were circulated that the dust destructor would provide all the steam which would be required for the electric lighting engines. The results have shown, however, that the demand for electrical energy has increased at a rate quite unexpected, and in consequence new generating plant had soon to be installed, which required more steam than the destructor could supply. In consequence coal-fed boilers had to be used, and the opponents of the scheme unhesitatingly condemned the whole undertaking in consequence. The fact remains that the dust destructor as a dust destructor has been entirely successful, although handicapped by the limited space around it for the storage of clinker. It has also provided large quantities of steam for the electric lighting department, and it is not the fault of either the consulting engineers or the Electric Lighting Committee that the demand for electric light has increased so much more rapidly than the dustbin refuse, which has to be cremated in the dust destructor. It only shows that the theory that every man makes enough dust to provide himself with light and power does not hold in Shoreditch.

The other point on which considerable misunderstanding was evidenced in certain of the speeches was as to whether the undertaking was financially successful. Mr. Bird, in the course of the dinner, stated that for the first four complete years of working the gross profits had amounted to £21,085, while the interest and repayments of loan which had to be paid had amounted to £19,177. The electric lighting department has a reserve fund of £2,000, and has contributed rather more than it should have done to the libraries and to the dust destructor department. In consequence of this, there is a temporary deficit in the accounts, which is obviously of no serious moment. The essential fact is that the supply at Shoreditch is given at a considerably lower rate than in any other district within the London area. For instance, for the year 1900 to 1901 the average price obtained per unit in Shoreditch was only 3·08d. for the private supply, which is 0·6d. below the average price for the next cheapest supply within the London area. It may seem to the uninitiated that a saving of just over ½d. per unit is a comparatively small item, but for the year in question Shoreditch would have made a further profit of £5,600 if it had increased its price per unit by that amount, and if the Electric Lighting Committee had not adopted the correct policy which should guide all municipal undertakings—*i.e.*, that no profits should be taken from the undertaking for the reduction of the general rates. The indirect advantage to the borough of this cheap supply is much more than is indicated by the above figures, as it helps the increase in the cabinet-making industry, to which Shoreditch owes so much of its prosperity.

In the original station there was only room for 1,455 kw. of generating plant, and some two years ago it was seen that this would soon be insufficient to deal with the demand. It was accordingly decided to build new additional works, where coal could be got in more cheaply, and where water for condensing purposes could be obtained. A suitable site having been found at the corner of Whiston-street and Bath-place, Haggerston, on the banks of the

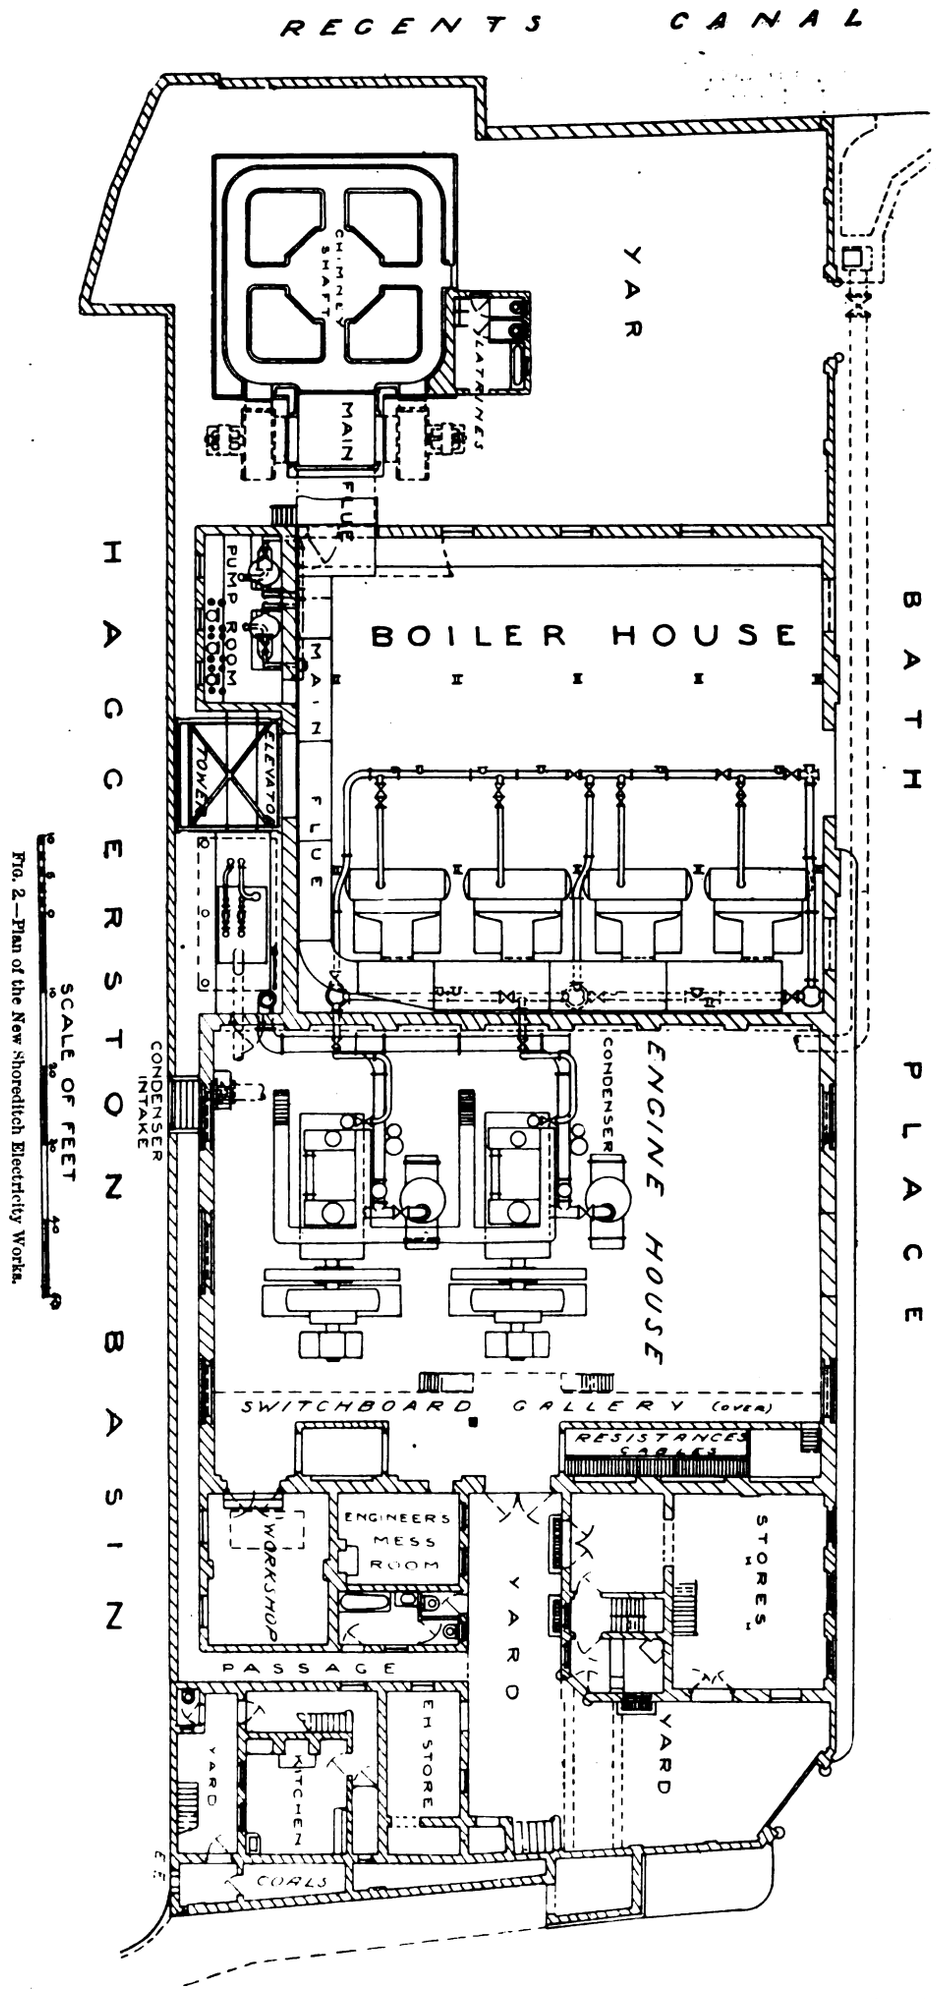

FIG. 2.—Plan of the New Shoreditch Electricity Works.

Regents Canal, the Borough Council instructed their consulting electrical engineers, Messrs. Kincaid, Waller, and Manville, to prepare a comprehensive scheme for the erection of a new power house which would provide for all

Digitized by Google

the future needs of the district. The scheme proposed by them has been adopted by the Council, and the works, of which the following is a description, have been completed under the supervision of Messrs. Kincaid, Waller, and Manville and Mr. C. Newton Russell, the borough electrical engineer. The design of the new power-house, as will be seen by the description and drawings, is on a large scale, although only two units of generating plant have at present been installed, but the engine-house and boiler-house are capable of extension to an extent that will allow the present output being multiplied many times; to such an extent, in fact, that it is inconceivable that the demand for an electricity supply in Shoreditch can in the future exceed the facilities offered by the Whiston-street site extensions.

Buildings.—The generating station occupies a site of about 19,800 super feet in area, at the corner of Whiston-street and Bath-street, Haggerston, with frontages to the Regents Canal and the Haggerston Basin, enabling coal to be delivered by barge, and providing a supply of condensing water. The buildings (Fig. 1 and 2) consist of a boiler-house 68ft. by 62ft., with pump-room adjoining, engine-house 78ft. 6in. by 59ft. 6in, with basement into which the condensing water and other pipes are taken. A subway for the cables leading from this basement to a chamber under the pavement in Whiston-street is provided for the feeder cables leaving the station. A transformer-room containing the continuous-current transformers for supplying the network in the neighbourhood of the generating station is provided, with workshop and stores also adjoining the engine-room. The switchboard gallery extends the whole length of the engine house, and is 11ft. above the floor-level. Chambers are provided below the gallery for the reception of the shunt regulating and other resistances, and for the accommodation of the cables proceeding to the machines and circuits. A room for the engineer in charge at this level leads direct on to the gallery. A handsome room, with ante-room having separate approach, is provided for the members of the committee. Accommodation for a resident engineer has been provided in a small house at the corner of the site, with entrance from Whiston-street. Separate rooms are provided for the men employed in the engine-house and boiler-house respectively, and each have their necessary lavatory accommodation. The chimney shaft, 180ft. in height, with an internal diameter of 10ft. at the top, is placed in the yard at the rear of the site and adjacent to the canal. The buildings are faced externally with picked Fletton bricks, relieved with red Leicestershire bricks. The engine-house is faced internally with Fletton bricks, having glazed brick dado and strings running round the walls, with glazed brick arches to the openings. The engine-room floor is laid with vitreous mosaic. The foundations of the chimney shaft and the main wall of the buildings are taken down to the London clay, a depth of about 21ft. The contractors for the buildings are Messrs. Johnson and Sons, of Leicester, and for the chimney shaft, Messrs. Storrs and Son, of Stalybridge.

Boiler-House Plant.—The boiler-house plant (Fig. 3) consists of four water-tube boilers of Messrs. Babcock and Wilcox marine type, having solid-drawn steel tubes. Each boiler has a heating surface of 2,720 square feet, and is fitted with economiser containing 350 square feet of heating surface, making a total heating surface in the four boilers of 10,880 square feet, and in the four economisers of 1,400 square feet, thus making a total heating surface in the four boilers and four economisers of 12,280 square feet. It will be noted that the floor space occupied is very much less than with boilers of the "land" type. Three of the boilers are hand fed, having an ordinary grate area of 73½ square feet, which makes a total grate area in the three boilers of 220½ square feet. The remaining boiler is fitted with a double 4ft. patent chain grate stoker made by Messrs. Babcock and Wilcox. The grate area of this boiler is 68 square feet, the total grate area in the four boilers being, therefore, 288½ square feet. These four boilers combined will produce about 50,000lb. of steam per hour, and are arranged along one side of the boiler-house, the space on the opposite side of the boiler-house being available for the accommodation of additional boilers whenever they are required. The products of combustion are conveyed from the boiler to the chimney through flues constructed of steel placed overhead. The flues are lagged externally by magnesia, which is held in position by means of external plates. A chamber has been provided at the base of the chimney shaft to which the main flue is connected, and is

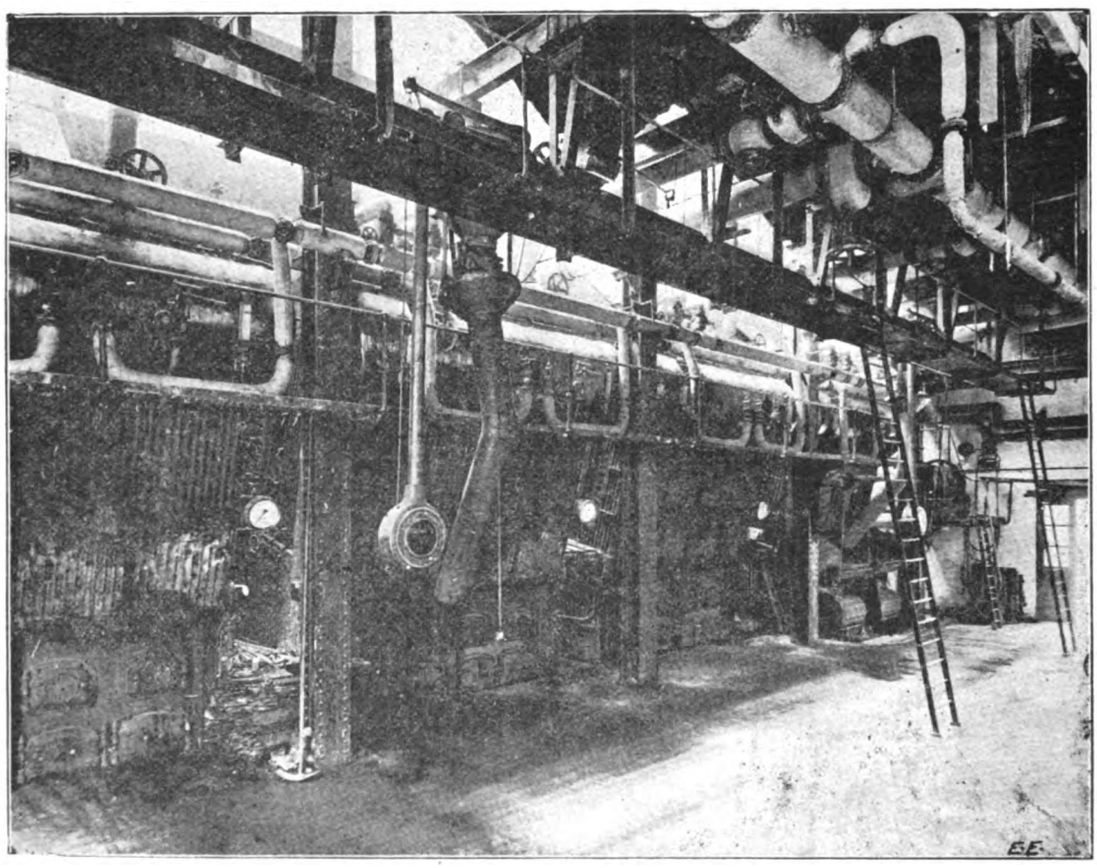

FIG. 3.—View of the Boiler-House, with Babcock-Wilcox Marine Boilers.

Digitized by Google

so arranged that induced-draught apparatus can be added subsequently.

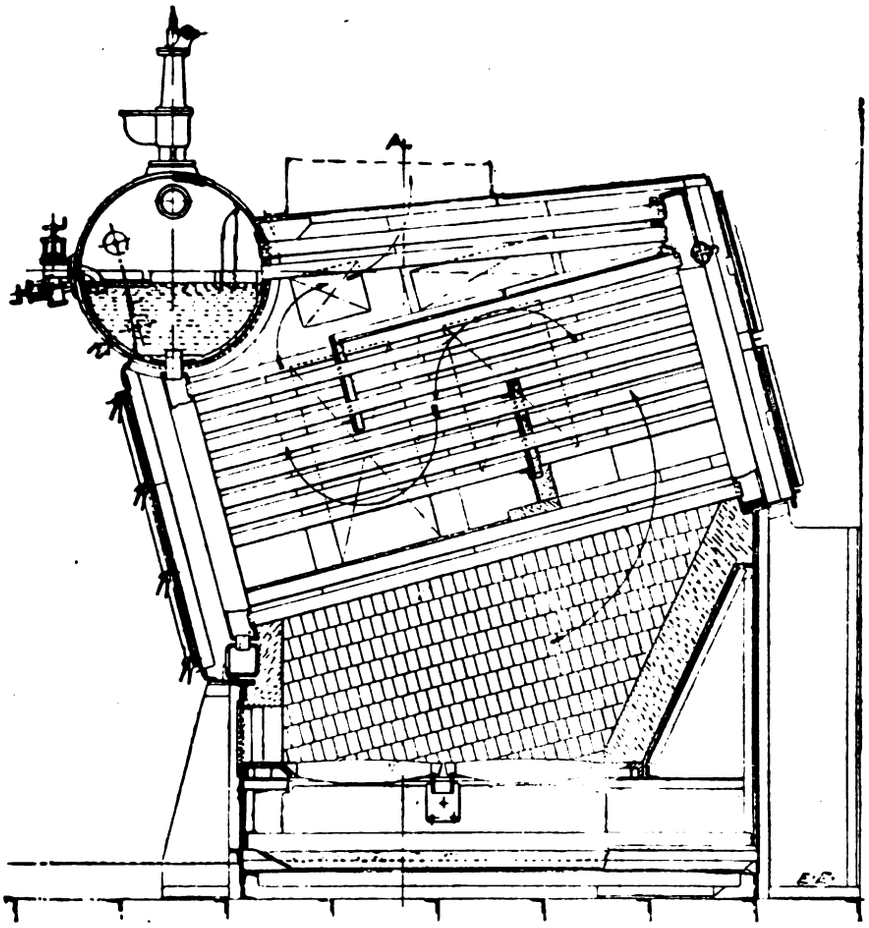

FIG. 4.—Section of the Babcock-Wilcox Marine Boiler.

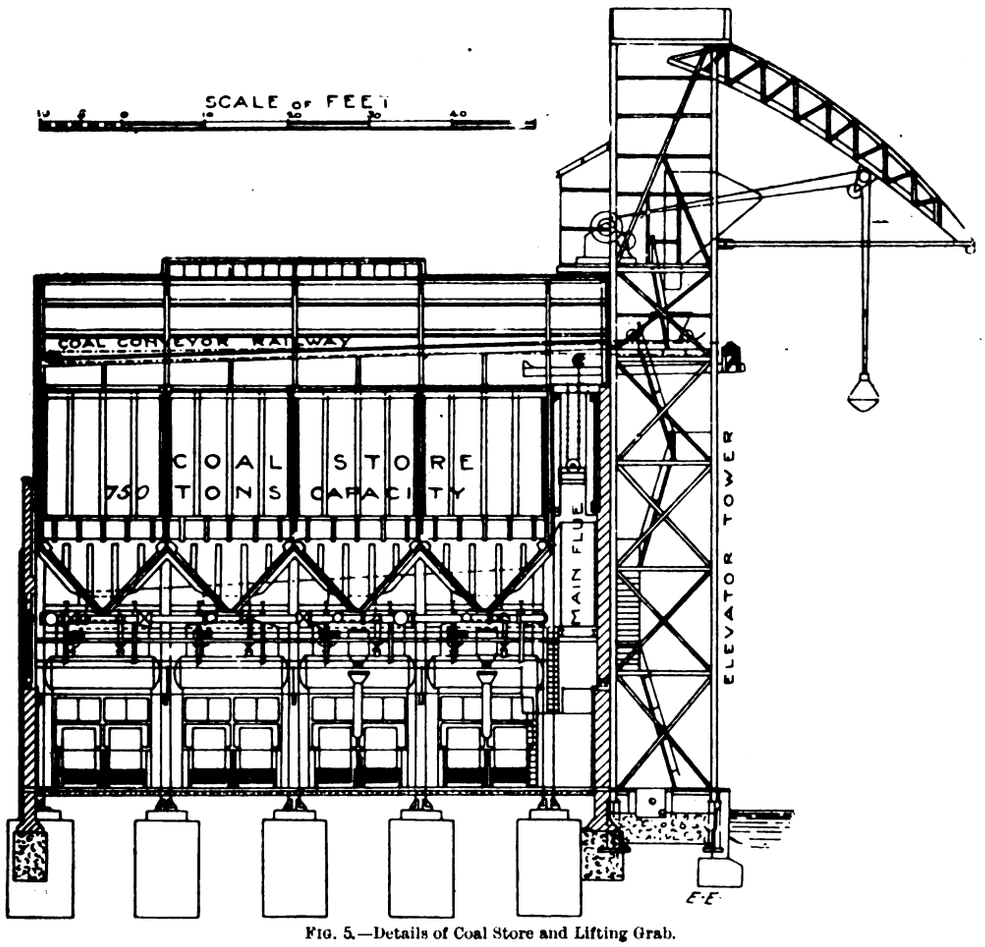

FIG. 5.—Details of Coal Store and Lifting Grab.

The boilers are supplied with coal from an overhead coal store (Fig. 5), having a total capacity of 750 tons, erected on steel stanchions above the stoking place in the centre of the boiler-house. Pockets with sloping sides are provided in the bottom of these bunkers to facilitate the discharge of the coal to the boilers. A special feature about the boiler-

Digitized by Google

house is the arrangement by which the coal is lifted from barges on the canal alongside the generating station, conveyed to the bunkers and afterwards to the boilers. The coal is lifted from barges by means of a hinged grab or shovel of half a ton capacity, which is projected from a boom of parabolic form extending over the canal. This apparatus is situated at the top of a tower constructed of steelwork placed near the edge of the canal at the end of the boiler-house. The parabolic form of boom enables the bunkers are provided with regulating valves, one being placed opposite the centre of each boiler, which enables the flow of the coal to be controlled. The coal is delivered by means of these valves into a hopper having a weighing apparatus, so as to correctly register the amount of coal delivered to the boilers. At the present the coal for the boilers which have not been fitted with mechanical stokers will be delivered on the floor in front of the boilers as the fireman requires it. In the case of the boiler fitted with

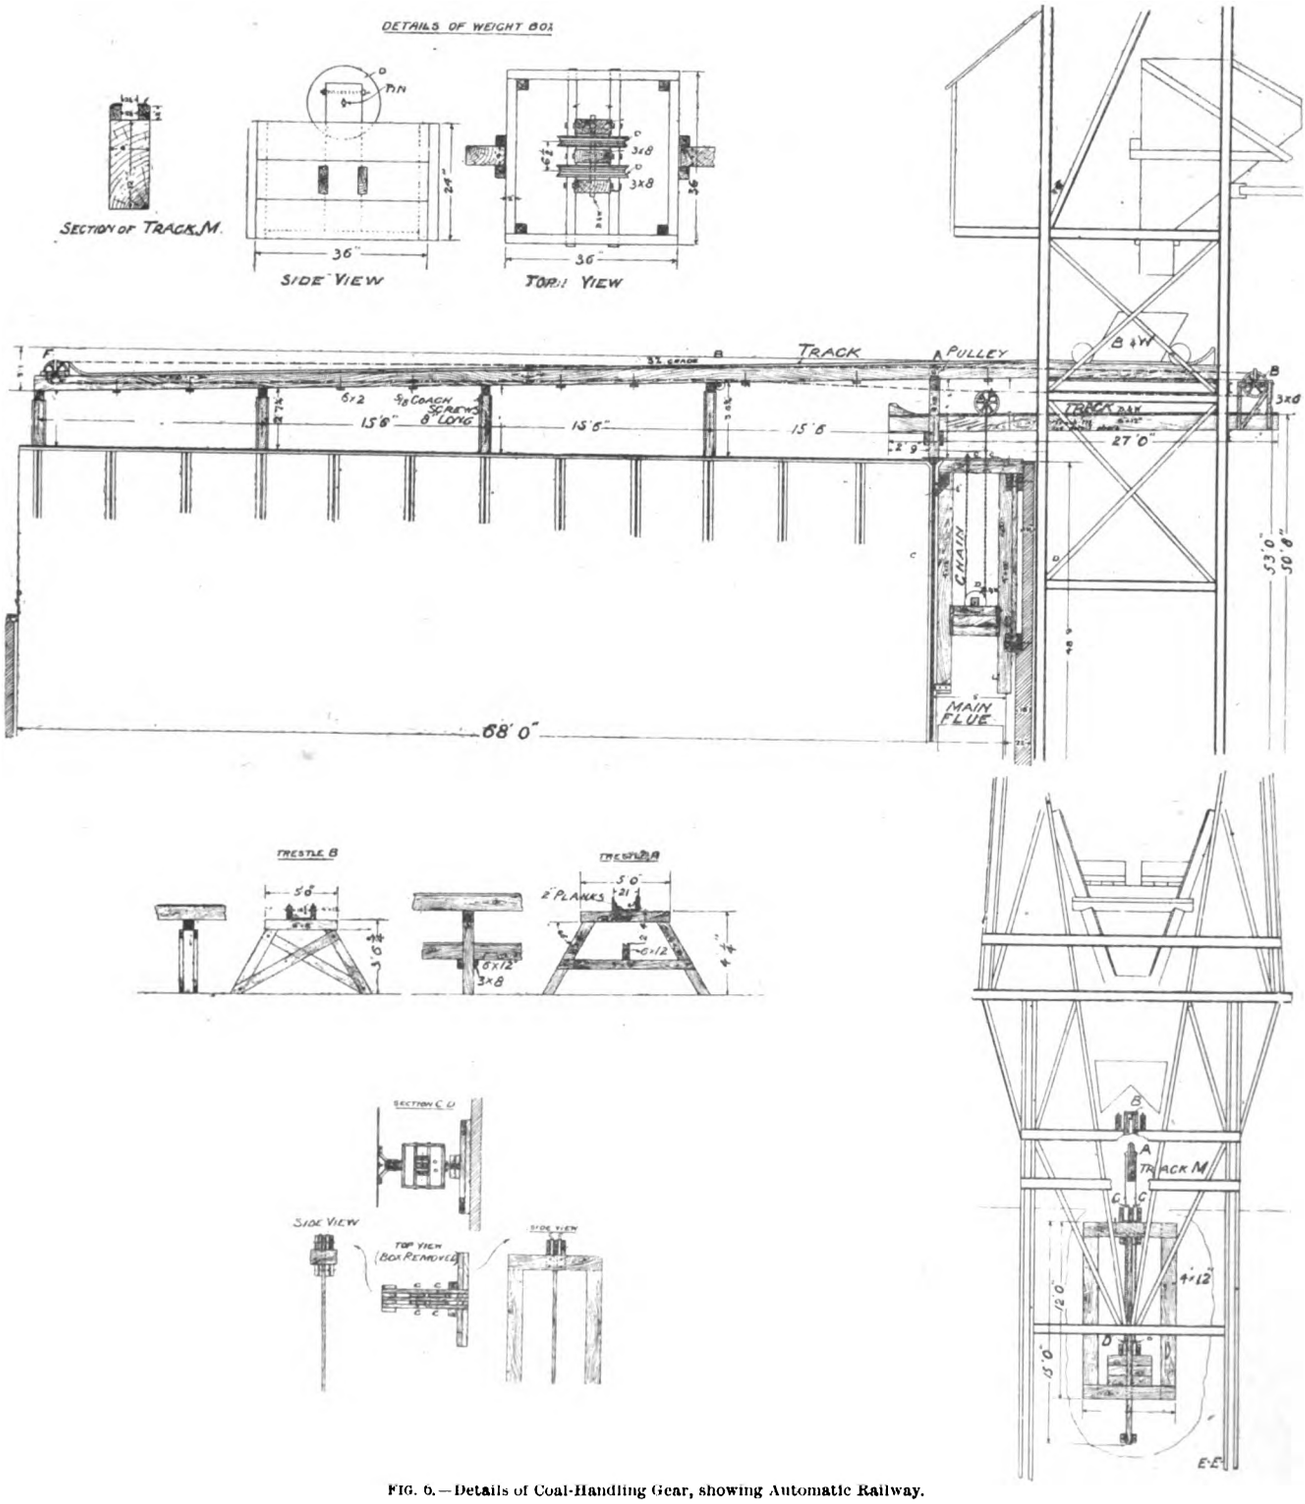

FIG. 6.—Details of Coal-Handling Gear, showing Automatic Railway.

load to be lifted vertically until it reaches its extreme elevation, when an inward movement takes place, at the end of which movement the coal is dumped into a hopper and delivered through a regulating duplex valve into an automatic wagon (Fig. 6), which, after being filled, is released and runs over the top of the bunkers, dumping the coal at any point where it is required. The hoist is driven by means of two electric motors of the enclosed type, supplied by the Westinghouse Company, the speed being regulated by a series parallel controller. Each of the openings at the bottom of the pockets beneath the coal a mechanical stoker, the coal will be delivered directly into the hopper in connection with the stoker.

The peculiar feature of this automatic railway (Fig. 6) consists in storing sufficient energy required by the loaded car descending an inclined track, the energy being utilised to return the empty car back to the place from whence it started after the load has been discharged. The loaded car runs down the inclined track, and when it has reached the end of its journey it has raised a counter-weight a certain height by means of the cable shown in the illustration, which the car picks up while running down the track.

Digitized by Google

The weight rises only a limited distance, but when the car has dumped its load of coal, which is from 20cwt. to 25cwt., the weight falls, and whilst so doing pushes the car a certain distance back up the track, the momentum gained being sufficient to carry the car the remainder of the way. One man only is needed to operate the railway, who starts the car when filled, but does not accompany it. The car runs down the inclined track, dumps its load, and hands it automatically to the workmen. It runs with great rapidity, making the trip of 100ft., dumping its load, and returning in about 30 seconds. Gangways are provided in the boiler-house for access to the fittings in front of the boilers and to the stop-valves on the main steam range. The coal-handling apparatus has been supplied by Messrs. Babcock and Wilcox, being of the Hunt Company's special design. The whole of the steelwork, comprising the coal storage bunkers, elevator tower, and roof for boiler-house, together with the overhead flues, have been supplied by Messrs. Peirson and Co., St. Dunstan's-hill, E.C. The feed pumps are three in number, two of them being capable of delivering 2,500 gallons per hour to the boilers, and the third 5,000 gallons per hour. They are of the C. and J. Weir Company's make, and deliver to the boilers through the feed mains, which are in duplicate, each main being provided with a separate filter and water-meter. The suction pipes to the feed pumps are also in duplicate, one pipe being connected to the overhead feed storage tank, the other pipe being connected to the hot-well. The feed-water storage tank is constructed of cast-iron plates, and is capable of holding 12,000 gallons of water. This tank is divided into two sections to enable either section to be cleaned without interfering with the continuity of the supply of water to the pumps. The hot-well consists of a galvanised iron tank having a capacity of 1,500 gallons. A special feature in connection with the hot-well is that it is placed upon a weighbridge, so as to provide a ready means of measuring the water discharged from the air-pump when carrying out tests on the plant.

The main steam-pipe (Fig. 2) is arranged in the form of a ring placed in the boiler-house, the main pipe being 10in. in bore, constructed of mild steel, with the flanges shrunk on and riveted. Jointing is avoided as much as possible, and with this in view the branch connections are made by means of flanged outlets of mild steel, riveted on to the main pipes. The ring is divided up into sections by means of straight-through valves, so as to limit the effect of any failure to the particular section of the ring affected. All valves are of the straight-through pattern with cast-steel bodies. The whole of the steam and feed piping, feed pumps, storage tank, etc., have been supplied by Messrs. Aiton and Co.

Engine-House Plant.—The engine-house plant consists of two vertical slow-speed Corliss compound steam-engines (Fig. 7), each direct-coupled to a continuous-current dynamo of 800 kw. capacity. Each engine is provided with its own condensing plant, consisting of surface condenser with air and circulating pump driven direct from the main engine. The engines are designed to run at a speed of

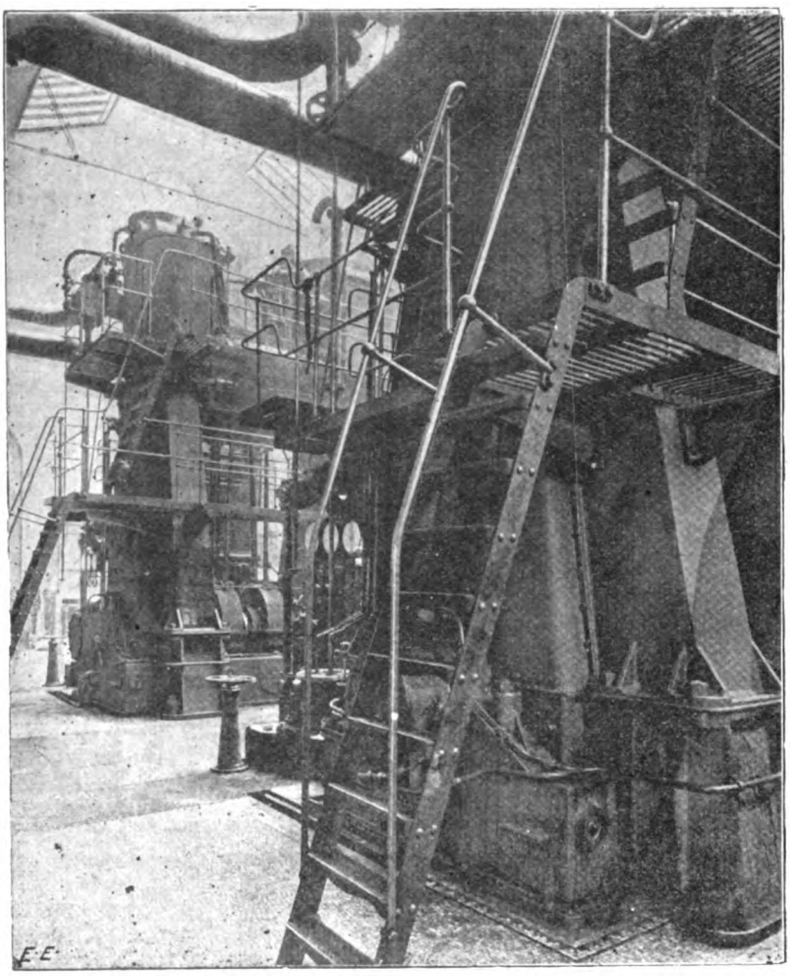

FIG. 7.—View of the Wallsend Slipway Company's Engines.

90 revolutions per minute, and are capable of developing from 1,300 i.h.p. to 1,400 i.h.p. The diameter of the high-pressure cylinder is 24½in., and the diameter of the low-pressure cylinder is 53in., stroke 42in. The crankshaft, generator bearings, connecting rod end and slides, are provided with forced lubrication under pressure, oil pumps being provided for this purpose working from the crank-shaft. The main standards are suitably enclosed to prevent oil splashing about, large doors and movable casings being provided to give access to the working parts. Both high and low pressure cylinders are both provided with automatic Corliss trip gear controlled by the governor, which is of Whitehead's isochronous type. In addition to this ordinary governor, an emergency governor of the inertia type is provided. The flywheel, weighing about 32 tons, is of the built-up type with steel tension arms. Steel rings are shrunk on the hub as an additional safeguard. Ladders and staging are provided for access to the valve gear and other working parts.

The generators (Fig. 8) are of the multipolar type, made

Digitized by Google

by the Westinghouse Company. The armature and commutator are built upon a ventilating cast-iron sleeve, forced on the engine shaft under pressure. The field castings are divided in a vertical plane, and are mounted on cast-iron sole-plates. The rated load of each of the machines is 730 amperes and 1,100 volts. The machines, however, are designed to carry an overload of 50 per cent. for two hours, if necessary, above this rating. The armature is of the slotted-drum type, having a multiple winding so arranged that the circuits will not become unbalanced by a slight displacement of the armature from the centre of the fields. The brushes, which are of carbon, are adjustable by means of a hand-wheel and worm gear, and the arms carrying the brushes are supported at the end next to the field casting, so as to leave the commutator free from obstruction. The arrangements for ventilation are very perfect in this type of machine, and open ducts are provided for this purpose throughout the armature to the spider core and windings, the design of the spider being such as to set up a forced current of air through these ventilating spaces. The exhaust steam from each engine passes through an oil separator on its way to the condenser. The condensers each have a cooling surface of 2,700 square feet. The air and circulating pumps are driven by means of levers from the high-pressure cross-head. The air-pumps are of the Edwards single-acting type, the circulating water pumps being of the double-acting type. The circulating water is taken from the basin in connection with the Regents Canal, and is returned through pipes down Bath-place into the main canal. An alternative exhaust to atmosphere with automatic release is also provided. The engines have been manufactured by the Wallsend Slipway and Engineering Company, and they also supplied the generators, together with exhaust and water pipes in connection with the engines and the condensers.

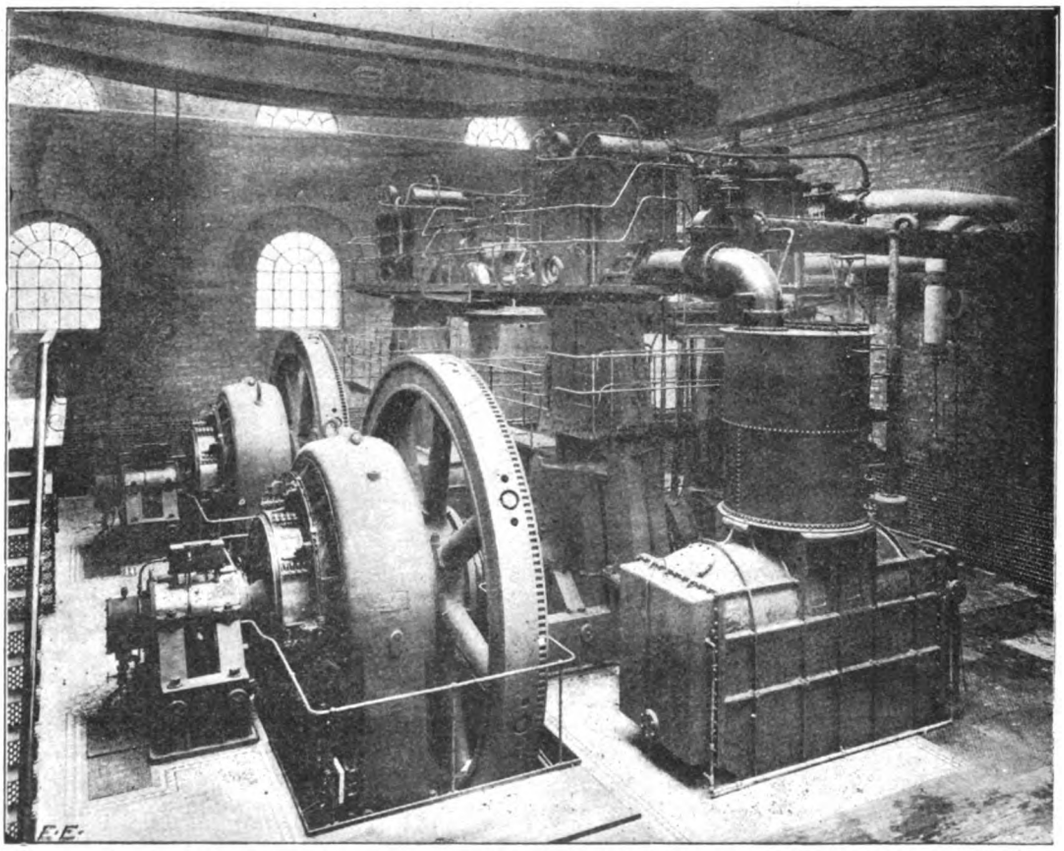

Fig. 8.—General View of the two 800-kw. Steam Dynamos, showing the Westinghouse Dynamos.

Switchboard.—As previously mentioned, the switchboard is placed on a gallery which runs the whole length of the engine-room, the high-tension portion being placed at one end, and the low-tension at the other. The high-tension board is divided into the following sections: (1) high-tension dynamo board (Fig. 9), comprising positive and negative dynamo panels for each generator, with paralleling panel in the centre; (2) high-tension trunk feeder board (Fig. 10), comprising positive and negative panels for two feeders; (3) high-tension transformer board, comprising panels for four transformers; (4) arc circuit board, with provision for three arc circuits. The low-tension board consists of positive and negative feeder panels for six low-tension feeders. This switchboard will be used in connection with the continuous-current transformers and for supplying the network in the neighbourhood of the station, and is arranged with plug system, whereby any transformer can be plugged on to any low-tension feeder. Both high and low tension switchboards have been supplied by Messrs. Cowans, of Manchester, the high-tension board being of their special design, the high-tension switches being mounted on horizontal slates, and the whole supported on an iron frame, which is placed against the face of the wall without the necessity of leaving a space behind for access to the working parts. All the main high-tension switches are provided with reverse-current cut-outs of the Andrews type, and the switches can also be opened by means of a hand trip gear. These switches break through about 1in. of water. The instruments are of Messrs. Evershed and Vignoles's make, with the exception of the voltmeters, which are of the Ayrton and Mather multicellular type. The recording instruments are by Messrs. Elliott Bros. A special feature in connection with the design of the switchboard is the chamber that is provided below the gallery to contain the various resistances and high-tension omnibus bars. The spindles for working the regulating resistances are brought up through the floor of the gallery, and are operated from a convenient height, cast-iron pillars and hand-wheels being provided. A light gangway is provided in the chamber below the board for convenient inspection of the various regulating switches and resistances. The high-tension omnibus bars, which are carried in the chamber below the gallery, as previously mentioned, are supported on oil insulators. In addition to supplying the switch boards for the Whiston-street generating station, Messrs. Cowans have supplied the trunk feeder panels at the receiving end of the trunk feeders at the old station in Coronet-street, and have supplied the additional switchgear for the two sub-stations at Reeves'-place and Evelyn-street respectively.

It will be seen from the above description that there are

Digitized by Google

some essentially novel features in this latest undertaking of the Shoreditch Borough Council. The marine type of

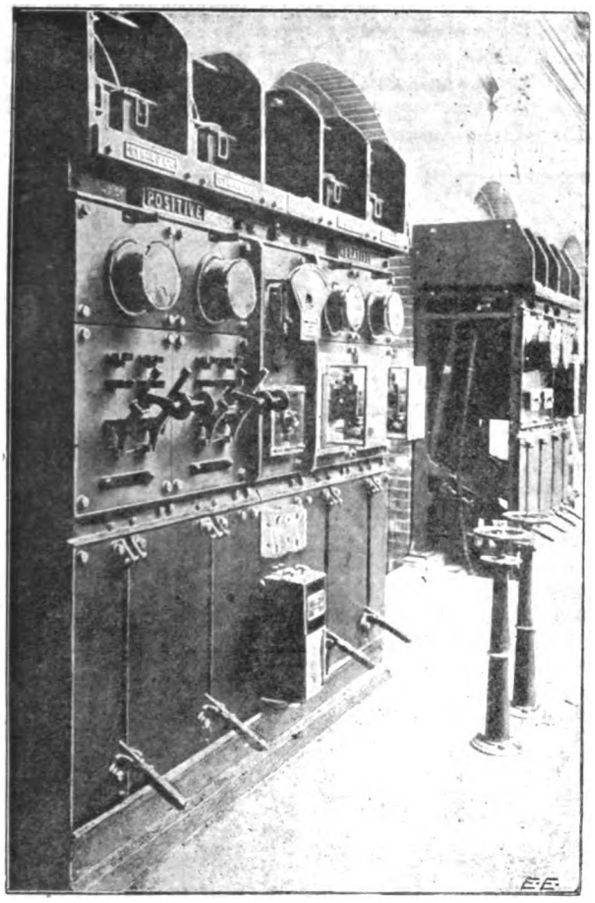

FIG. 9.—The Dynamo Board at Shoreditch.

Babcock and Wilcox boilers have, we believe, never before been utilised for service on land, and are expected to give

FIG. 10.—The Shoreditch Feeder Board.

the most efficient results, whilst the comparatively small ground space occupied by them in comparison with their steam capacity makes them eminently suitable for a large electric generating station. The automatic railway for handling and trimming the coal in the overhead bunkers is also a novel feature in this country. It will be noticed that the system of supply adopted for the new generating station is similar to that supplied by the Council in their first generating station—*i.e.*, high-pressure continuous-current—being generated at the power-house at about 1,100 volts, delivered to sub-stations located in various portions of the area, where the current is transformed down to the pressure required for the service to consumers' premises through continuous-current motor-transformers, consisting of machines with one field and a double-wound armature. The distribution from the sub-station through the streets to consumers' premises is on the two-wire system.

POWER DISTRIBUTION IN CALIFORNIA.

Through the courtesy of the Stanley Electric Manufacturing Company, we are able to give herewith a map which clearly shows the enormous development in electric power transmission and distribution which has taken place

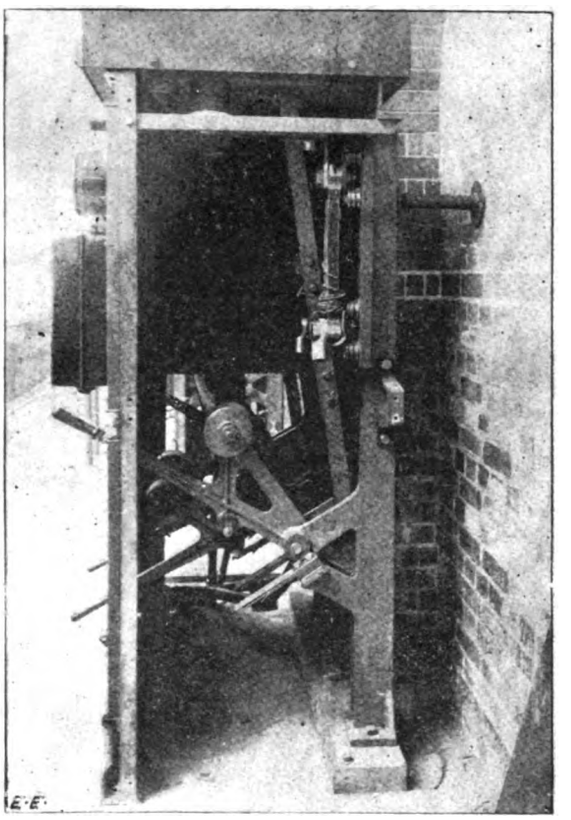

FIG. 11.—Side View, showing the Levers of the Cowans Oil-Break Switches.

in California. The lines on this map indicate the routes of the overhead electric wires of the two large companies which up to the present have been to a certain extent working in opposition. We understand, however, that these two companies—the Standard Electric and the Bay Countries Power Company—have been temporarily connected together, and that there is every likelihood of their becoming united into a single undertaking. The whole of the lines on the accompanying map are completed and ready for work, and they are working regularly throughout the 24 hours, with the following exceptions: the 46-mile line from Stockton to the Standard Company's power house at Electra, the line from Redwood City to San Francisco. We understand, however, that by the time we go to press these lines will be in regular service. The following are the details of the various sections of wire used on the lines indicated on the maps, and at the same time we give their lengths in detail. The sizes of the wires are given in circular mils, which is the square of the diameter in thousandths of an inch.

From Electra to Stockton, 46 miles. One circuit, 471,034 c.m., aluminium cable.

PHYSICAL SOCIETY.—The ordinary meeting of this Society, announced for the 27th inst, will take place this evening at five o'clock, on account of the coronation festivities.

THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

TENTH ANNUAL MEETING, DUSSELDORF.

[BY OUR OWN CORRESPONDENT.]

The Verband Deutscher Elektrotechniker seem particularly adept in their choice of localities for their annual meetings. Düsseldorf, on the Rhine, where the tenth annual meeting of the Verband has just been held, is an attraction of itself, being known, in fact, as the garden town of Germany. Its many gardens and beautifully shaded lakes have won for it this reputation. To the casual visitor it comes as a surprise to learn that this charming and cleanly town is in close proximity to a thriving iron industry. But it is, nevertheless, the case, and it is only due to the happy chance which has situated the ironworks, with their attendant forest of belching chimneys, in the east that the town enjoys almost entire immunity from the disadvantages of its industry. The accompanying illustrations will serve to give some idea of the natural attractions of the place. Added to these, the town at present combines the attraction of an industrial exhibition

Digitized by Google

of unusual extent and interest. Especially in the electrical and heavy engineering sections the exhibition is in a manner unique. To details we hope to proceed later. The proceedings of the Verband commenced on Thursday, 12th inst., when council and committee meetings were held in the morning and afternoon respectively, while in the evening the members present for the occasion, and their wives, were entertained by the town of Düsseldorf to supper in the Tonhalle. One of the accompanying illustrations shows an exterior view of this building, which provided magnificent accommodation for both the social and business meetings of the Verband. The evening was spent in social intercourse. Long-parted friends made merriment over the Rhine and Moselle wines, which, for once, took the place of lager, a full military band assisting in the entertainment. Naturally under such circumstances the guests departed with good appetites for the morrow's business. At all events, very good progress was made with the general business of the meeting on the following Friday morning.

In opening the meeting, the PRESIDENT (Prof. Hartmann, of Frankfort) referred to the Verband's especial indebtedness to the mayor and town of Düsseldorf for the welcome which had been extended to them. The coincidence of the exhibition enabled the Verband to combine the enjoyment of the beautiful with the appreciation of the useful. With regard to the sections of the exhibition which appealed to them most, although finality in design and application had been by no means reached, the progress made in electrical science was nevertheless very apparent. Turning to another question, the 10 years' existence of the Verband was not in itself a cause for jubilation, but they had some satisfaction in knowing that the necessity for electrical engineers to act in common accord was sufficiently appreciated. In industrial circles great hopes were held of the united action of electrical engineers, and these had been realised. With regard to scientific and technical progress, the Verband had cause to rejoice, although they had not reached the goal aimed at. In order that the supremacy of the electrical industry in Germany might be upheld, it was essential that constant improvement should be made. A few days previously a meeting of German electrical engineers had been held to form an association for the protection of the scientific interests of the profession. In conclusion, Prof. Hartmann pointed out that it was necessary that electrical engineers should pay more attention to their commercial training, an opportunity of which was offered latterly by the connecting of technical schools with commercial schools, and suggested that, perhaps, the time was not far distant when commercial schools would be attached to all universities.

Assurances of welcome to the town were subsequently addressed to the meeting by the mayor and others.

Mr. GISBERT KAPP, the general secretary of the Verband, then read the annual report. From this it appeared that the membership of the Verband had increased by 21 since the corresponding date last year, the total membership now amounting to 3,133. At the commencement of the present financial year the value of the Verband's assets stood at about £6,500. The book published by the Verband showing the duties imposed on the more important electrical articles by foreign countries had involved a loss so far of £20, the demand for copies falling considerably below expectations. The circulation of the Verband's official organ, the *Elektrotechnische Zeitschrift*, had increased by 8 per cent. since the corresponding date last year. At the end of the year 1901 its circulation, including the 4,087 copies distributed to members of the Verband and Elektrotechnische Verein, amounted to 7,700 copies.

(To be continued.)

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

The following is the text of the official programme of the seventh annual convention of the above association, to be opened in London on the 2nd of next month :

Meetings.—The meetings on July 2, 4, and 5 will be held at the Institution of Mechanical Engineers, Storey's-gate, S.W., and on July 3 at the Royal Agricultural Hall, Islington.

Tickets.—Applications for visitors' tickets and for advance proofs of papers, etc., must be made to the secretary of the association, Mr. C. McArthur Butler, St. James's Hall, Piccadilly, London, W.

Hotel Accommodation.—The Westminster Palace Hotel, London, S.W., will be the headquarters of the council during the convention.

WEDNESDAY, JULY 2.

General meeting, at 10 a.m., at the Institution of Mechanical Engineers. The Chairman of the London County Council (John McDougall, Esq.) has kindly consented to be present to meet and welcome the association. Presidential address by Mr. J. H. Rider, electrical engineer, London County Council tramways.

The following papers will then be read and discussed : (1) "Double-Current Generators and their Application," by Mr. E. T. Ruthven Murray, electrical engineer, Willesden Urban District Council ; (2) "High-Tension Continuous-Current Systems," by Mr. A. S. Barnard, city electrical engineer, Hull. The meeting will adjourn at 1 p.m.

At 2.15 p.m. prompt brakes will leave the Westminster Palace Hotel for the generating station of the Central London Railway at Shepherd's Bush. At 3.45 p.m. the brakes will be ready to convey the party to either of the following, afterwards returning to the Westminster Palace Hotel : the generating station of the Metropolitan Electric Supply Company, Limited, Willesden (this is a bulk supply station, generating and distributing two-phase alternating current at 10,000 volts) ; or to the works of the Incandescent Electric Lamp Company, Limited, Brook Green, W. (the "Robertson" incandescent electric lamp is manufactured at these works).

THURSDAY, JULY 3.

General meeting at the Agricultural Hall, Islington, by the kind invitation of the Tramways and Light Railways Exhibition Committee. The entrance to the exhibition is in Upper-street, Islington. Admission by special ticket. Members to meet in the committee-room of the exhibition at 10.30 a.m., where the Exhibition Committee will receive them, and the party will then proceed to inspect the exhibits. Luncheon will be served at 1 p.m. to members, by special invitation of the Exhibition Committee. At 2.30 p.m. an adjournment will be made to Berners Hall (in the building), when the following papers will be read and discussed : (1) "Steam-Turbines," by Mr. S. E. Fedden, city electrical engineer, Sheffield ; (2) "The Correct Type of Engine for Large Generating Stations," by Mr. A. A. Day, borough electrical engineer, Bolton.

FRIDAY, JULY 4.

General meeting, at 10 a.m., at the Institution of Mechanical Engineers. The following papers will be read and discussed : (1) "Some Notes *re* Earthing," by Mr. H. Faraday Proctor, city electrical engineer, Bristol ; (2) "Two *v.* Three Wire Distribution," by Mr. J. F. C. Snell, borough electrical engineer, Sunderland. The meeting will adjourn at 1 p.m.

During the afternoon the following works will be open for inspection : the generating station of the City of London Electric Lighting Company, Limited, at Bankside ; or the conduit tramway construction on the Tooting lines of the London County Council.

The association smoking concert will be held in the Banqueting Hall of the St. James's Restaurant on Friday, July 4, at 8 p.m. (evening dress).

SATURDAY, JULY 5.

Annual general business meeting, at 10.30 a.m., at the Institution of Mechanical Engineers, when all members, associate members, and associates are particularly requested to attend. Agenda : place of meeting for convention of 1903 ; election of president, officers, and council for 1903 ; annual report of the council ; balance-sheet for year ending Dec. 31, 1901 ; amount of annual subscription ; any other competent business.

BENEVOLENT FUND.

A special general meeting of the contributors to the benevolent fund of the association will be held at the Institution of Mechanical Engineers, Storey's-gate, St. James's Park, S.W., at the close of the annual general business meeting, for the purpose of considering the following resolution, passed at a council meeting of the association held at the Westminster Palace Hotel, London, on Friday, Feb. 21, 1902 : "That it be a recommendation from this council to a special general meeting of the subscribers, to be held after the 1902 convention, to discontinue the benevolent fund and to hand over accrued donations and subscriptions to the like fund of the Institution of Electrical Engineers."

LEIGH ELECTRICITY WORKS.

The following is an abstract of the annual report of Mr. John Foster, engineer and manager, to the chairman, vice-chairman, and members of the Tramways and Electricity Committee on the work of the undertaking during the 12 months ending March 31 last :

Practically no money has been spent in regard to new extensions during the year except an instalment of £1,000 on the cost of the new steam dynamo, which was paid in March of this year. The total length of mains now laid is as follows : ·3in., 18 yards ; ·25in., 2,289 yards ; ·15in., 1,584 yards ; ·1in., 1,905 yards ; ·05in., 4,629 yards—a total length of 5 miles 1,625 yards ; the total number of services laid during the year being 49. The consumers now number 128 ; number of 8 c.p. lamps, 9,403 ; number of motors, 52 ; units sold, 150,610 (plus 438 public clock) ; maximum load in kilowatts, 140, with a load factor of 12·31 per cent. In commenting upon the progress made during the year I can only say that it is highly satisfactory, being 96 per cent. over the previous year,

Digitized by Google

Analysis of Accounts for Year ending March 31, 1902.

Capital expenditure to March 31	£17,373 4 4
Revenue from electricity supply	1,989 17 2
Revenue from meter and motor rents and other sources	70 13 4
Total revenue	2,060 10 6
Total costs	1,150 9 3
Gross profit before providing for interest charges and sinking fund	910 1 3
Percentage of gross profit to capital (outlay during year being averaged)	6·43 per cent.
Interest on loans	419 2 10
Sinking fund	410 0 0
Percentage of sinking fund to capital (outlay during year being averaged)	2·89 per cent.
Financial result after payment of all charges (profit)	80 18 5
Capacity of dynamos, etc., March 31 (kilowatts)	200
Maximum load reached (kilowatts)	140
Load factor	12·31 per cent.
Number of 8-c.p. lamps connected March 31 (arcs, incandescents, and motors, equivalent in 8 c.p.)	15,853
Number of units sold and public clock	151,048
Units sold per 8-c.p. lamp (connections during the year being averaged)	13·8
Price charged—Private lighting	7d. and 2½d., or 5d. and 3d., less 10 per cent.
Power	3d. and ½d. and 1¼d.
Average price obtained—Private supply	4·13
Average price obtained—Power	1·45

Analysis of Costs.

	1902. £	s.	d.	Per unit sold d.
1. Coal and other fuel	221	8	7	·36
2. Oil, waste, water, and engine-room stores	82	5	8	·13
3. Wages of workmen	265	11	2	·42
4. Repairs, etc., of buildings, plant, etc.	66	0	10	·10
Works cost	£635	6	3	1·01
5. Rents, rates, and taxes	130	5	0	·20
6. Management expenses, salaries, etc.	196	9	4	·31
Total generation and distribution costs	£962	0	7	1·52
7. Interest and sinking fund costs	829	2	10	1·32
Total costs	£1,791	3	5	2·84
8. Lamps, carbons, and fittings	24	3	7	—
9. First annual instalment of 10 per cent. on capital cost of motors	84	3	8	—
10. Cost of altering fittings at technical school	80	1	5	—
	£1,979	12	1	—

In deciding upon the merits of the net profit for the past financial year, I wish to draw your attention to the two special charges numbered 7 and 8 in the above analysis of costs. In the first item I find that the instalment on the capital cost of motors has been based on the total cost at the end of March, 1902, whereas, if the instalment had been set aside from the time each bill for the motors was paid, this amount would have been reduced by at least £28. This amount, coupled with the £80. 11s. 5d. the cost of altering the fittings at the technical school, would increase the net profit to £189. 13s. 2d., which I think you will agree is highly satisfactory on the second year's working. The following is a summary of financial results: capital expended, £17.373. 4s. 4d.; average charge per unit, 3·17d.; gross profit, £910. 1s. 3d.; percentage to average capital outlay, 6·43 per cent.; interest and sinking fund, £829. 2s. 10d.; net result—surplus, £80. 18s. 5d. The gross profit is averaged on the mean of the capital outlay at March 31, 1901 and 1902.

SOUTHPORT ELECTRICITY WORKS.

The annual report of the Southport borough engineer for the year ended March 31 last states that during that period the growth of the undertaking has been satisfactory. The number of new consumers connected has been up to the average of the past few years, and the output of units for tramway purposes has steadily increased. During the year Nos. 3, 4, 5, and 6 boilers were reset upon their foundations owing to settlement having taken place. Undoubtedly the most important boiler house accessory that has been installed during the year has been the water-softening apparatus supplied by the Desrumaux Automatic Water Softener and Purifier Company, Limited. It is quite automatic in its action, and is capable of softening and filtering 8,500 gallons of water per hour, and requires the minimum of attention. Since it has been in operation its effects on the boilers have been most apparent; instead of requiring three weeks to scale a boiler after running 1,000 working hours, it is only necessary to brush the flues and sides and wash out, an operation taking one to two days only. Its equivalent value is at least two additional boilers under the old method of working. It should affect the working costs beneficially. There is at present installed the following plant of a total capacity of 4,000 h.p.: Lighting—(two) 125-kw. alternators, 250 i.h.p.; (one) 300-kw. alternator, 500 i.h.p.; (two) 600-kw. alternators, 1,000 i.h.p. Traction—(three) 200-kw. dynamos, 350 i.h.p. The Belliss 1,000-h.p. triple-expansion engine and Ferranti 600-kw. alternator were set to work early in November, and proved of very great service during the winter. The whole of the engine-room plant has been maintained in thorough working order, and has given very little trouble. A centrifugal pump, driven by either a continuous or alternating motor, has been installed, and is capable of returning the condensing water of 2,000 h.p. to the reservoir. By this arrangement the works are self-contained, from a condensing point of view, and thus are independent of the brooks if necessary. Owing to the existing six feeders from the works to the town being overloaded during the past winter, necessitating running at a high station pressure, and to increase the margin of safety, it has become necessary to lay four additional feeders, and this work is well in hand, and will be completed in the course of a few weeks. House transformers have been reduced to a minimum and consumers connected to the low-tension network. A new sub-station has been erected at the junction of Portland-street and Lord-street, and is the latest practice in this class of work, and has proved of considerable convenience. The lamp connections during the year amount to 7,087 8-c.p. lamps, and the additional consumers 111, making a total of 63,737 lamps and 1,021 consumers. Six motors have been connected during the year, equalling 7½ h.p. The total amount of cable now laid is as follows: Lighting, 58 miles 532 yards; pilot wires, 12 miles. Tramway, 11 miles 870 yards; pilot wires, 8 miles 880 yards. Telephone, 5 miles 680 yards. Five wiring installations have been carried out during the year, the total value of the contracts entered into amounting to £146. The surplus for the year, after paying all charges, amounts to £1,682, and as £1,754 was promised in relief of the rates, there is a deficit of £68. The deficit last year was £520, so together with the £2,000 promised towards the rates for the present financial year the department is committed to £2,588. This represents a gross profit of approximately £12,500. There are several charges included in last year's working which will not appear in the present year, and he anticipates that all demands will be more than met. The maximum amount the Electricity Committee will be able to hand over towards the relief of the rates is £2,000, until a substantial reserve fund has been built up to depreciate obsolete plant. The gross profit for the year is £10,704, as against £7,292 the previous year, being a return of 7·24 per cent. on the capital (outlay during the year being averaged). The interest charges require £4,317, and £4,705 goes towards the sinking fund. Since the inauguration of the undertaking the sum of £15,382 has been paid in reduction of debt. The units sold to ordinary consumers have advanced from 731,777 to 798,450, an increase of only 9 per cent. The units sold to the Tramways Committee amount to 416,043, and to the Southport Tramways Company 120,881. The actual increase of units sold for the year, including public lighting, is 438,437, or 43 per cent. The income per unit sold for all purposes has dropped from 3·36d. to 2·98d. The total working costs per unit sold have decreased from 1·65d. to 1·23d. There has been a reduction on each of the six items, coal having the largest decrease—viz., ·17d. The average price paid for fuel was 10s. 1d. per ton, delivered at the works, as against 13s. 6d. for the previous year. In competition for premier position for the lowest working costs amongst the municipal electricity supply undertakings, Southport now occupies fourth place, as against tenth last year. Owing to the decrease in the price of fuel, the better supply of water for the boilers, and the rearrangement of the distribution system in the town, the working costs for the present year should be amongst the best in the country.

EASTBOURNE ELECTRICITY WORKS.

The report of the borough accountant of Eastbourne for the year ended March 31 last states that the total income from the electricity undertaking, after making due provision for allowances and bad debts, &c., amounts to £15,258. 9s. 1d., and the total expenditure on the same account is £6,219. 8s. 1d., leaving a gross profit of £10,039. 0s. 3d. After defraying the interest and contribution for redemption of debt out of the above profit, there is a net surplus amounting to £3,262. 6s. 10d. This has been added to the profit of previous years, and the amount to the credit of this account is now £5,078. 9s. 7d., as shown in the balance-sheet. The capital expenditure in respect of which permanent borrowing has not yet taken place is £25,294. 5s. 9d., and, assuming that stock is issued on the same terms as last, the sinking fund and interest in respect of this expenditure will be £2,194 per annum, with a further prospective charge in respect of additional capital expenditure to which the Council are already pledged. This, however, will not reduce the profit at present standing to the credit of the revenue account, as it is proposed to make the contribution to the sinking fund out of the profits earned during the year ending March 31 next. It, however, forms an element in the consideration of any scheme for charging a reduced price or any other method of appropriating the profit, as in the near future the charges for sinking fund and interest, in addition to those already borne (and including the £2,194 already mentioned), will reach at least £3,100 per annum. The question of depreciation is one which should receive careful attention. At present no provision is made.

APPOINTMENTS VACANT.

Assistant Engineer.—The Oban Burgh Commissioners will shortly advertise for an assistant engineer at a salary of £100 per annum.

Assistant Superintendents (5), Indian Telegraph Department, commencing salary 4,200 rupees, June 30. See advertisement.

Clerk of Works, Batley Corporation electricity station, 50s. per week, June 27. See advertisement.

Distribution Engineer.—The London County Council will shortly advertise for a distributing engineer at a salary of £350 per annum.

Shift Engineers, Blackpool Corporation electricity works, £125 per annum, June 23; Hull Corporation electricity works, £78 per annum, rising to £130 in two years. See advertisements.

ELECTRICAL LEGISLATION.

The deputation to the President of the Board of Trade from the Institution of Electrical Engineers on Wednesday last received a courteous hearing from Mr. Gerald Balfour, whose reply is given *in extenso* elsewhere in this issue. The members of the deputation, under the able leadership of Mr. James Swinburne, made a good case to show that the electrical industry in this country had been hindered by legislation. In his reply, Mr. Balfour clearly pointed out, what is equally true, that the electrical legislation of this country is no means the only factor to be considered when looking for the reason why England is to a certain extent behind America, Germany, and Switzerland. This, as he showed, is particularly the case with America, which is a new country, sparsely inhabited, and with towns growing up like mushrooms. The real difference, however, lies in the fact that new developments have few established interests to contend with in a new country as compared to those existing in an older country like our own, in which good progress has been made in other branches of engineering. Still, Mr. Balfour frankly admitted the need of modification in electrical legislation, both for electric lighting and power and for tramways. He stated that the Government had gone so far as to draft two Bills with this object, but that there is no hope of either being proceeded with this year. The one reason for this is evidently that strong opposition is expected to these measures on behalf of municipal authorities, and these authorities have large parliamentary influence. Thus, while there are cases in which local authorities have abused the veto given them by electrical legislation over tramway and electric lighting undertakings, it does not follow that this veto is always abused, and, hence, that the consent of the local authorities should not be required. There is no doubt that if this were done, and every case of new tram ways had to be fought out in a Parliamentary Committee between the tramway promoters and the corporations through whose areas the proposed tramways would pass the procedure of obtaining tramway orders would be even more cumbersome and difficult than at present. It seems to us that the power of dispensing with the consent of the local authority should be placed either with the Board of Trade, or with a small committee of the House of Commons to be appointed annually. If this were done, the committee would soon ascertain the cases in which the local authority was unduly obstructing a public convenience which ought to be granted. The result of the deputation, as far as the demand for a Royal Commission to consider the subject of electrical legislation is concerned, seems hardly likely to be successful, as the President of the Board of Trade does not see his way to recommend the Cabinet to appoint such a commission. There was, however, another matter brought forward in which there is more hope of immediate action than in any prompt change of legislation. The deputation urged that the electrical staff of the Board of Trade ought to be increased, and that the regulations issued by the same Board should be modified. At the present time the quality of the staff is all that can be desired, but the vast amount of routine work in connection with electrical inspection of new tramways, etc., and the holding of enquiries on accidents, completely occupies the staff, so that there is no time for the revision of regulations and for the due consideration of the needs of our rapidly-growing industry. As Mr. Swinburne directly pointed out, the existing regulations were drawn up for lighting and tramway schemes of a parochial scale, whereas they are now hampering the distribution of electrical energy over large areas, and of tramway systems providing intercommunication between numerous towns. We give

Digitized by Google

elsewhere in this issue a map of the overhead lines for distributing electricity in California. These lines would not, in our opinion, have been provided for the distribution of energy over the enormous areas involved if the authorities of that State had insisted on the use of underground cables. The area supplied as a whole at the present time in California is, roughly, one hundred and eighty miles long by one hundred and forty miles wide, and it would be absurd to expect regulations drawn up for the control of an electrical system for a town to be applicable for such an area. We trust that the practical outcome of the deputation will be an increase in the electrical staff of the Board of Trade, and that as a result the regulations issued by that body may be promptly revised and extended to meet the requirements of the day. In the meanwhile, it is well to remember that, in spite of the *Times* and the half-penny papers, the electrical industry in this country is not in the state depicted by their expert writers. Taking electric lighting alone, we are far ahead of the United States and the Continent both as regards practice and the cost of supply. As regards power distribution, it is sure that California would not possess the system it does if coal cost there only a few shillings per ton, as it does in our manufacturing centres.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

AIR-PUMPS.

SIR,—In a letter in the current issue of your paper, "T Square" claims to have shown that the four "glaringly misleading statements" made by him, and to which I took exception, are substantially correct. With your permission I will reply to his "arguments" as enumerated by him.

Firstly, I denied his statement that 26in. of vacuum could "certainly not be obtained" with a jet condenser, and he now seeks to prove the truth of his statement by bringing forward what he calls a quotation from Seaton—viz.: "With a jet condenser a vacuum of 24in. is considered good, and 25in. is as much as possible." As a matter of fact, Seaton was referring to the old, now obsolete, marine-type jet condenser, and really wrote "24in. *was* considered fairly good, and 25in. *was* as much as *was* possible with most condensers." The kinder view to take of "T Square's" misquotation of Seaton in his own favour is to ascribe it to inexcusable carelessness. In spite of "T Square's" blind assertion to the contrary, it is a very simple matter to obtain a vaccum of 26in. with a jet condenser fitted with a single-acting vertical air-pump, and there are scores of condensers of the above type giving a vacuum of 27in. every day. As instance, a condenser recently erected by Benj. Goodfellow at Shaw and Jardine's cotton mills, Buttler-street, Manchester, and others which I could name. "T Square's" statement that 26in. of vacuum cannot be obtained with the above type of condenser, is tantamount to an admission that he knows nothing about the subject on which he is writing.

Secondly, I pointed out that "T Square" failed to take into account any air to be dealt with by the air-pump except such as "leaks in." All water that has been exposed any length of time to the atmosphere contains, mechanically mixed with it, a large percentage of air, as it would hardly pay to previously effect their separation. This mixture is, of course, drawn into the condenser. "T Square" says that this air "leaks in." I suppose that after the air has "leaked in" to the water and then into the condenser it "leaks" out again, with a little assistance from the air-pump, and that jet condensers are always "leaky" condensers. This, Sir, is childish quibbling.

Thirdly, "T Square" contests my statement that the dimensions given by him for the diameter of the air-pump is so small; his own figures contradict him. Thus he makes a great point of asserting that the speed of the pump bucket must not exceed that at which the water will follow it, and with this end in view he limits the speed of the bucket to 8ft. per second. The bucket, of course, having the same speed on the down stroke as on the up stroke, the water and air drawn in have to pass through the bucket valve, and he limits the speed through this valve to 10ft. per second. Now, it is a simple matter of arithmetic that in order to obtain this result the area through the bucket valve must be 80 per cent. that of the area of the bucket. "T Square" had better try to design an air pump bucket which will allow 80 per cent. of its area for the passage of water.

Fourthly, "T Square," having lately consulted Seaton, admits that in stating that if a double acting pump were used instead of a single-acting pump it need only be half the size of the latter, he was guilty of an assertion directly opposed to the true facts of the case.

Now, Sir, apart from the consideration of trespassing upon your valuable space, I have neither the time nor the inclination to argue with a person who persists in asserting that 26in. of vacuum cannot be obtained with a simple jet condenser, when he has only to enquire of the first engineer he may meet to find out that the thing is being done every day. Until he takes the trouble to ascertain the truth, or to prove that in the instance mentioned above 27in. of vacuum is not obtained, I shall take no further notice of his future effusions.

In conclusion, his awe-struck remark about my temerity in "launching out into print" is as quaint as his sketch. I should have thought that he would have written that I had "leaked" into print.—Yours, etc.,

E. COSGRAVE.

SIR,—May I venture to make a few remarks in connection with the rather heated controversy which is being carried on in your paper. I am at present with a firm who make a speciality of high-class mill engines, and these engines are almost invariably fitted with jet condensers. The above firm are at any time prepared to guarantee that their condensers will give a vacuum of 27in. when fitted with a vertical air-pump, and 26in where a double-acting horizontal air-pump is employed. If I may say so without giving the appearance of discourtesy, "T Square" has fallen into the not uncommon error of under-estimating the amount of air to be removed by his pump. Every 13 cubic feet of injection water may be assumed to contain one cubic foot of air. After the air has entered the condenser—the vacuum being taken at 26in.—it will expand to about eight times its original volume owing to the rise in temperature and fall in pressure which it undergoes (by Boyle's and Gay Lussac's laws). Thus for every 13 cubic feet of water injected into the condenser, eight cubic feet of air must be pumped out. The air-pump should be designed to deal with this volume of air as well as the water as a perfect pump, and *afterwards* be multiplied by the coefficient of efficiency.

I trust that "T Square" will take these remarks in the spirit in which they are written.—Yours, etc,

DRAUGHTSMAN.

SIR,—As disclosed by the correspondence, there is apparently an absurd difference in practice in regard to designing air-pumps. For instance, well-known authorities make a large allowance in capacity of pump upon the calculated amount of water for condensing a certain amount of steam, the usual thing being to allow five to six times the capacity of what is required by calculation for pumping the cooling and condensed water. On the other hand, the American practice appears to be based on the lines of what "T Square" gives.

Have English engineers been so tied to their grandfather's practice to be so far behind, or is it that the Americans cannot give the duty they guarantee to do, and obtain orders on false statements? Notwithstanding their small capacities, they will solemnly guarantee 26in. and 27in., and declare that in certain installations they are getting 28in. in ordinary work.—Yours, etc.,

June 17, 1902. PUZZLED.

ELECTRICAL ENTERPRISE AND LEGISLATION.

An influential deputation representing the Institution of Electrical Engineers and the electrical industry generally waited upon the President of the Board of Trade on Wednesday at the offices of the Board of Trade, Whitehall-gardens, on the subject of electrical enterprise and legislation in this country. The deputation, headed by Mr. James Swinburne, president of the Institution, consisted of the following gentlemen: Lord Kelvin, Mr. Sydney Dobson, Mr. S. Z. de Ferranti (vice-president), Sir Michael Foster, K.C.B., M.P., Lord Greenock, Lieut. Colonel Crompton, C.B., Mr. H. E. Harrison, Mr. J. E. Kingsbury, Mr. Henry Lea, Mr. W. Langdon, Mr. A. J. Lawson, Mr. W. L. Madgen, Sir Henry Mance, Mr. H. A. Mavor, Mr. W. M. Mordey, Mr. S. Morse, Mr. W. H. Patchell, Prof. J. Perry, F.R.S., Mr. J. Clifton Robinson, Sir J. F. L. Rolleston, M.P., the Earl of Rosse, Mr. R. P. Sellon, Mr. C. E. Spagnoletti, Mr. A. A. C. Swinton, Prof. S. P. Thompson (past-president), Dr. R. Spence Watson, Major-General C. E. Webber, C.B., and Sir Thomas Wrightson, Bart., M.P. Lord Kelvin having formally introduced the deputation,

Mr. SWINBURNE laid before the President of the Board of Trade the general grounds on which it was urged fresh legislation should be enacted in relation to the electrical industry. He emphasised the fact that they did not come there to oppose municipal trading, but they earnestly asked to have checked the abuse of the legal powers at present enjoyed by local authorities, who, they urged, ought not to have power to prevent schemes even coming before Parliament on their own merits. As to compulsory purchase, they urged that that was now only a legal incubus on the industry. They also asked for simpler, more efficient, and less costly procedure in connection with Parliamentary Committees. In regard to the department of which Mr. Balfour was the head, they were well satisfied with the officers and inspectors of the Board of Trade, but they suggested that a more liberal supply from the Treasury should be made to enable a larger electrical staff to be maintained. The regulations of the Board of Trade governing the electrical industry were behindhand, and they asked that the subject of overhead wires generally might be reopened. The limits of size of converters and trunk mains also required revision. Though they would urge certain improvements in the Department itself, they were very much more concerned in the broader question of the effect of legislation on the industry, which had lagged behind compared with other countries and with other industries in this country. Municipalisation might be a good thing if carried out on sound principles, but without complaining of it, they felt that the powers of local authorities were capable of very serious abuse. They thought, therefore, the effect of municipal trading, as far as it concerned the electrical industry, should be investigated, so that his Majesty's Government might know whether it was a good thing, not for municipalities considered alone, but for the community at large, having regard to questions of engineering, local indebtedness, housing, rapid transit, and concentration in cities. In conclusion, the deputation urged the Government to appoint a Royal Commission to consider the whole question of electrical legislation.

Colonel CROMPTON supplemented the above remarks with a few instances of the manner in which municipal local veto had damaged the interests of private electrical enterprise. He was followed by Dr. R. SPENCE WATSON, Mr. SYDNEY MORSE, Sir MICHAEL FOSTER, and Mr. S. Z. DE FERRANTI, all of whom spoke of the evils of the absolute local veto possessed by local authorities in the matter of electric lighting and tramways, and complained of the inefficiency of the Board of Trade regulations now in force.

Mr. GERALD BALFOUR said he did not think there was any special question he wished to ask. He understood that the regulations complained of referred especially to overhead wires, voltage variation limits, and the one supply through one feeder. With regard to overhead wires, he thought he might say that the Board of Trade would be prepared to consider every case on its merits, and not lay down any hard-and-fast rules. As an example of this he mentioned the case of St. Helens, where overhead wires had been permitted for the purpose of supply. In respect to variation of voltage limits, he was not aware that this point had been brought before him on any previous occasion, but he might say that the Board of Trade was extremely anxious to meet the reasonable requirements of the promoters as far as possible, and he did not think they would find that the Board were anxious to place any unnecessary obstacles in their way whatever. With regard to any change in the regulations, he should be most anxious to receive from the committee of the Institution of Electrical Engineers which had considered this matter any suggestions they might have to offer, and he could promise that those suggestions would receive the fullest consideration at the hands of the Government. He did not quite understand, however, the suggestion that had been made, that the Board of Trade should increase its electrical staff, or in what particular way such an increase would assist the objects the deputation had in view. Of course, if it could be shown that the staff was insufficient for the work it had to perform, then it was a matter for consideration. He did not think, however, that an increase of the staff would enable the Board of Trade to march more with the times than it did, and, as he had already said, he did not know in what way such an increase would promote the objects the deputation had in view.

Mr. FERRANTI said that matters in the electrical industry were changed so much and developments had been so rapid in recent years, that the electrical staff of the Board of Trade had a very difficult task to keep up with it and to consider a change of regulations from time to time. He thought these regulations should be changed at certain periods, or at least modified so as to fit the circumstances of the case. With regard to the overhead wires, for instance, promoters did not want to stand the chance of the regulations being altered when a scheme was going commercially. He suggested that the regulations should precede the demand—that was to say, that the Board of Trade should investigate what was being done in other countries, and should see that the regulations did not in any way hamper the industry.

Mr. BALFOUR: You mean that the staff is so much overworked it cannot keep pace with the progress of the industry.

Mr. SWINBURNE thought the Institution would welcome the opportunity of being at liberty to furnish the Board of Trade with a statement of the regulations they should like to have considered.

Mr. BALFOUR: I should be very glad to have such a statement.

Mr. SWINBURNE: In answer to what you have said, sir, I think the mere fact that things are in such a position is in itself an admission that the electrical staff of the Board of Trade is insufficient to keep up with the times and to originate regulations.

Mr. PATCHELL said it was the uncertainty of the regulations which tied them up For instance, they thought they were restricted by the regulations in the amount of voltage they were entitled to use, and also as to what thickness of insulation to fit that voltage was required. At the present time the regulations as regards extra-high tension were in a state of uncertainty, and it was not clear whether they applied to extra-high tension or only to high tension. Another matter was as regards the earthing of the neutral point of the three-phase system. From an engineering point of view this was bad.

Mr. BALFOUR: You urge that the regulations are not so precise as to carry their meaning on the face of them?

Mr. PATCHELL said that was so

In the course of some further discussion Mr. BALFOUR stated that the regulations were only meant to apply to ordinary cases, exceptional cases being dealt with on their merits. It was impossible to do this if any hard-and-fast rules were laid down.

Mr. PATCHELL suggested that as what Mr. Balfour called exceptional cases had become quite ordinary cases by the development of the industry, the time had now come to consider a change of the regulations.

Mr. BALFOUR then made his reply on the question of

Digitized by Google

legislation. He said: Lord Kelvin and Gentlemen,—I fully recognise the very great importance of the subject which you have brought before me to-day, and to a very large extent I am in sympathy with much that has been said by the various speakers who have addressed me. I am afraid it is an undeniable proposition that the electrical industry in this country is behind what it is in America, in Germany, and, perhaps, some other of the Continental countries. I doubt, however, if that backwardness is to be entirely, or, perhaps, even chiefly, attributed to defects in our legislation, or to oppressive regulations or to the abuse of their powers by local authorities. I do not for a moment mean to contend that the legislation applying to the electrical industry is not susceptible to considerable amendment, or that our regulations may not in some instances have proved too restrictive, or that the local authorities have not abused their powers. I doubt moreover whether that really accounts for the comparative backwardness of this country in electrical industry in relation to other countries, such as America, Germany, and Switzerland. This must always be recollected: America is a new country, very sparsely inhabited, with towns growing up like mushrooms, above all, with comparatively few established interests to contend with. The field is open, and capital can rapidly flow in through those channels. Things are different in this country. It is an old country, with a very dense population, with a large number of strongly established interests, and established interests always produce that instinct of conservatism which we have very strongly developed in this country. I believe it is these fundamental conditions rather than any actual legal enactments, which have tended to retard the development of the electrical industry in Great Britain as compared with the same industry in other countries. But, while I hold that view, I do not for a moment contend, as I have already said, that changes in the direction indicated might not be of a very beneficial character. It appears to me, however, after listening to the various speakers, that the really important question is not so much that of any impediments thrown directly by the Legislature in the way of the development of the industry, as of the power which the Legislature has given the local authorities to veto schemes. Now, with regard to this matter I have got to consider two branches of the subject—electric supply and electric traction. In the case of electric traction on tramways, so far as these matters are still determined by the provisions of the Act of 1870, the local authority has an absolute veto—an absolute veto as regards provisional orders—and by a Standing Order of the House of Commons, it also possesses an absolute veto upon any measure which it is proposed to promote by Bill. To some extent the evils flowing from that state of things have been limited by the adoption in many cases of light railway procedure, even where the scheme is, in the proper sense of the term, a railway on the road or a tramway. But it is true that the Light Railway Commissioners, and also the Board of Trade, have considered themselves more or less bound by the legislation laid down in the Tramways Act and the Standing Order. I do not think that they have gone to the length of giving to the local authority absolute veto, but undoubtedly they are influenced by the legislation on this subject. As regards traction, this subject has been investigated of late by a departmental committee appointed by the Board of Trade, on which both promoters and local authorities were represented. As the result of the deliberations of that committee a Bill has been drafted which, I think, will go very far to meet all the reasonable objections which have been urged against the present powers of the local authorities to-day. I trust that that measure when introduced will prove satisfactory to both parties—both to promoters and local authorities. But, gentlemen, it is idle to conceal from ourselves that the local authorities represent a very great power in this country, and they can see that it is strongly to their interest to possess, if not absolute veto, a *locus standi* which will enable them to have their views freely expressed. I would remind you, as an illustration of the difficulties attending this matter, that the other day when an attempt was made to alter the Standing Order in the House of Commons, the motion giving effect to that view was received in so hostile a manner that practically the mover of it did not bring it to the vote. I only remind you of that to show the difficulties which stand in the way so long as local authorities take so strong a view of the powers which ought to be reserved to them in connection with these enterprises. Nevertheless, in spite of that refusal of the House of Commons to alter this Standing Order, I have considerable hope that the compromise arrived at by the Committee, and now embodied in the Bill to which I have referred, will be found satisfactory to all parties, and be an adequate solution of this difficult question. As regards electrical supply, the case is somewhat different. The House of Commons Committee of 1898 has already sat on the question of electrical supply, and has made a series of recommendations. Where an enterprise for the purpose of electrical supply is promoted by Bill, I believe that the committees of Parliament now usually act upon the recommendations of that committee, but legislation would be required in order to enable the Board of Trade to adopt the recommendations of that committee in connection with provisional orders. We have also got a Bill ready to give effect to the recommendations of that committee. I cannot hold out much hope, I am afraid, that we shall be able to pass either that Bill or the other Bill to which I have referred during the present session, which, as you know, is already occupied with important measures. But it is the desire of the Board of Trade, when opportunity may offer, to introduce and to press both of these measures, and, therefore, I think you will see that we are by no means insensible to the recommendations you have brought forward, and that of our own accord we have already taken preliminary steps to introduce fresh legislation. I would say no more about the regulations, because that matter has already been referred to in the discussion we have had. I will only repeat that the Board of Trade will always be happy to listen to any suggestions that may come from so important a body as that represented here to-day, and that we are really as anxious as you can be to secure that the public interest shall be properly served by the development of that great industry which you represent.

Mr. SWINBURNE pointed out that what the deputation was asking was that a Royal Commission should be appointed to consider the whole subject.

Mr. BALFOUR said he would be quite ready to consult his colleagues on the matter. It was a question for the Cabinet, not for him, and he would put the views of this deputation before it. At the same time, he did not feel in a position at the present time to say that he should recommend his colleagues to adopt that suggestion.

Colonel CROMPTON reminded the President that he had said nothing in his reply upon the question of the electrical staff of the Board of Trade.

Mr. BALFOUR: That is a matter which I will carefully consider.

Mr. SWINBURNE having thanked Mr. Balfour,

The deputation withdrew.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

491. Explain in detail why triple-concentric, lead-covered cables cannot be used for three-phase work. What advantages are obtained by using three-core cables for this work?—E. M.

492. Is there any remedy, other than a metallic return, for reducing the cross-talk of a single earth-return telephone circuit, whose line runs parallel for 10 miles with other telephone wires, which have in no way any connection to the telephone in question. Loud noises, and other conversations, are heard even better than its own.—S. B. W.

ANSWERS.

Question No. 485.—Why is the iron regulating resistance of a Nernst lamp enclosed in a vacuum tube?

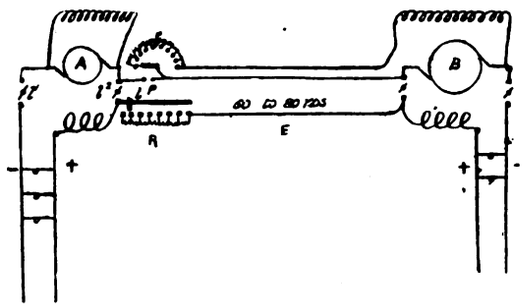
Best Answer to No. 485 (*awarded* 10*s.*).—It is a well-known fact that an ordinary electric incandescent lamp consists of the filament, composed of some substance treated with carbon to make it conductive, which is enclosed in a vacuum in a glass bulb; this is for the reason that when the filament became incandescent, it shall not be burnt up. Now, nothing can burn without the presence of oxygen, so if all the oxygen be exhausted from the bulb, it cannot be burnt up. Air contains oxygen as well as several other gases, nitrogen, carbon dioxide, argon, etc., to a greater or less extent, so all the air is exhausted from the bulb, and then the filament cannot be burnt up or oxidised. Exactly the same is the case in the iron regulating resistance in the Nernst lamp. When the current is switched on this gets hot, and when hot would be more readily oxidised than when cold if exposed to the air. So this, like the filament of a lamp, is enclosed in a vacuum. Though the heated iron wire may not get hot enough to burn up straight away if in air, it would gradually get oxidised right through, and then would act like a complete break in the circuit, as it would not conduct, and being in series with the glower, this would go out. It also might fall to pieces. The substances of which the glower is composed have a *negative* coefficient of resistance—that is, are more conductive the hotter they are—so if a current were passed through this alone, it would burn out very quickly. To counteract this, something must be put in series with it with a slightly bigger *positive* coefficient of resistance—that is, the resistance of the latter body increases slightly more than the resistance of the glower diminishes for a given rise in temperature of the glower. This being so, it is impossible, with the voltage for which the glower is designed, for the current to get so big as to burn the glower out. The substance satisfying these conditions as to slightly greater *positive* coefficient of resistance than the glower's *negative* coefficient is iron; hence the regulating resistance of a Nernst lamp consists of iron wire in a vacuum tube.—E. R. ALEXANDER.

Answer to No. 485 (*awarded* 5*s.*).—If the iron were not enclosed in a vacuum tube, it would tarnish and oxidise very rapidly, even if the air surrounding it were always dry. Black scales of oxide would be formed on its surface, and it is very doubtful whether its life would ever be so long as 24 hours before it failed. It has to be remembered that the temperature of the fine iron wire is very nearly red heat when the current is passing. For example, in the one-ampere size of Nernst lamp sold by the Electrical Company, Charing Cross-road, for use on 200-volt circuits, the iron regulating resistance takes 20 volts and the luminous rod or glower 180 volts. Hence 20 watts, or half the power taken by an 8-c.p. lamp, is expended in the iron wire, and therefore its temperature is very high, and it would oxidise in the open air with great rapidity. When enclosed in a vacuum tube I have never known one to fail, and have had one in circuit with three different glowers for over 1,000 hours, and the only sign of wear is the tarnishing of the brass cap at the end of the glass tube.—J. C. R.

Answer to No. 485 (*awarded* 5*s.*).—The resistance of the filaments used in Nernst lamps varies inversely with the current, in the same way as the resistance of the arc does. Consequently, if the potential difference applied to filament increases ever so little, the current will increase; this will cause a decrease in the resistance of the filament, leading to a further rise in current, and so the lamp becomes unstable. Similarly, if the potential difference decrease a little, the current will decrease and resistance increase, causing a further reduction in the current, the lamp again becoming unstable. To obviate this instability, a steadying resistance in series with the filament is necessary, acting in the same way as the steadying resistance in an arc lamp. In order that this resistance shall be as compact as possible, it is made of iron and run at such a current density that it is maintained at a red heat. It has to be sealed in a vacuum tube to prevent oxidation and consequent change in resistance. In the latest form of Nernst lamp a different form of resistance is used, which does not need to be enclosed in a vacuum.—PERCY H. HARDING.

Question No. 486.— I have two dynamos in separate engine-houses, distant about 60 or 80 yards, both compound-wound, one 200 volts, 100 amperes; the other 250 volts, 200 amperes. I might say that the engine driving the larger machine doesn't govern very accurately, the variation in voltage being as much as 15 or 20. Can I run the two in parallel at 220 volts? If so, I should like all necessary diagrams and particulars; if not, the reasons why. Of course, I mean for each machine to remain where it is. The machines are by different makers.

Answer to No. 486 (*awarded* 7*s.* 6*d.*).—In reply to question by "Doubtful," No 486, I think the following method is the nearest solution of this problem. In the accompanying diagram, A is the dynamo designed to give 100 amperes at 200 volts—total output, 20,000 watts; and B, the one to give 200 amperes at 250 volts, or 50,000 watts.



"Doubtful" must not forget that compound-wound dynamos, if well designed, only work satisfactorily under the conditions they were designed for. He wants A machine to give 20,000 watts at a potential of 220 volts, which means about 90 amperes at 220 volts, but this reduction in the amperes would mean a corresponding reduction in the ampere-turns of the series coil, and this, instead of reducing, we want to increase. B machine is required to give 50,000 watts at a potential of 220 volts. This works out about 227 amperes at 220 volts. This increase of the amperes would mean an increase in the ampere-turns of the series coil, if we neglect increased lost volts in armature and cross ampere-turns. What is wanted to neutralise these two effects, which act in opposition to the present requirements, and which are in themselves exactly opposite in their action, is some means whereby the increased current in dynamo B can be made to give increased excitation to dynamo A, without in any way increasing the ampere-turns of its own series coil. The first thing to do is to insert a resistance in the shunt of B machine, so that it may be cut down to 200 volts on open circuit. The series coils of A machine must now be put in parallel with the series coils of B through a variable resistance, R.

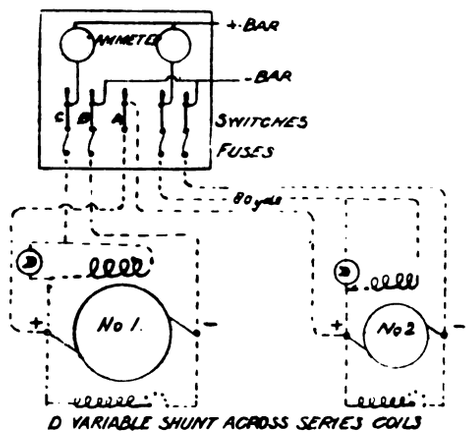
Suppose it is desired to parallel A with B: the latter we will assume is already carrying load at 220 volts and, say, 225 amperes, to obtain which the shunt resistance, r, had to be inserted to compensate for the over-compounding effect due to the increased amperage. Run up A machine to full speed and voltage—viz., 200 volts—turn switch, l, to first contact of R; this puts current through series coil of A and increases its potential, which can be adjusted by means of rheostat, R, to the same potential as B The effect of shunting current past the series coils of B will cause a drop of potential on B, which must be compensated for by cutting out all the shunt resistance, r. As soon as the potential of A is the same as B, switches l^1 l^2 can be made, and the two dynamos will now divide the load in proportion to their horse-power, the lead, E, simply acting as an equalising bar in the usual way. It is possible the dynamos will not show the same self-regulating properties as when running separately, owing to the change in potential and

Digitized by Google

current creating an alteration in their characteristic curves. If there were no losses, the voltage when the two are in parallel would be $\frac{200 + 250}{2} = 225$ volts, but owing to increased drop in armature of B machine and cross ampere-turns of same (which through the shunting of increased current past its series coils and round the series coils of A) is not compensated for, we may safely allow a drop of five volts.

The above arrangement will allow of A machine being paralleled with B, B machine being put in parallel with A, B run independently at 200, 220, or 250 volts; but A can only be made to give 200 volts unless in parallel with B. I have placed resistance, R, and shunt rheostat, *r*, in the engine-house of A dynamo, because I think it will be most suitable; but it can be placed in engine-house of B if desired, thus saving 60 or 80 yards of shunt lead and return. "Doubtful" will require a paralleling voltmeter with jack terminals to fit into terminals, *p*, also 60 or 80 yards of armoured cable, say $^{7}/_{20}$ S.W.G., and the two resistances referred to above.—J. C. S.

Answer to No. 486 (*awarded 7s. 6d.*).—To run the machines in parallel, the first thing to do is to so alter the machines so that they will each give 220 volts at their terminals. This may be accomplished in several ways: (1) by fixing smaller diameter pulley on No. 2 and larger diameter pulley on No. 1, thus increasing the speed of No. 2 to give the 20 extra volts, and reducing speed of No. 1 to reduce volts from 250 to 220; (2) by reducing the air-gap between the armature and pole-pieces of No. 2 and increasing same in No. 1, if the design of the machines permits; (3) by increasing and decreasing the speed of the engines; (4) by inserting resistance in the shunt field of No. 1 and removing it from No. 2.



D VARIABLE SHUNT ACROSS SERIES COILS

We will now assume that the two machines give 220 volts on open circuit, and that the series coils will maintain this pressure at full load; a switchboard similar to the accompanying sketch should be fixed preferably near the larger machine, as we shall then only require mains between the engine-houses to convey the energy from the small machine. Three cables of sufficient cross-section to carry 100 amperes without appreciable loss will have to be run from No. 2 to the engine-house containing No. 1 machine and coupled up as shown on sketch. The cable coupling the positive brushes of each machine directly together is termed an equaliser, as it equalises any difference of potential between these two machines and keeps the same pressure across their shunts; but it also prevents any reversal of polarity in either machine, and when the switch A is closed (which should be the first operation) current from the running machine is sent round the series coils of the standing machine, and ensures the polarity being the same in each case. An ammeter should be coupled in circuit with each machine so that the attendants can observe if they are each taking their respective load, and a variable resistance should be connected as a shunt across the series coils to adjust the load on each machine. The hunting of the large engine should be stopped. It may be that a larger flywheel is required, or the valves and governor require adjusting. If No. 2 is loaded up, and it is required to couple No. 1 in parallel, run up No. 1 to about normal speed, close switches A and B, then adjust the field of No. 1 so that its voltage is about equal to that of No. 2, then close switch C, and adjust the shunt across the series coils so that No. 1 gets its share of the load.—A. C.

Answer to No. 486 (*awarded 5s.*).—The arrangement proposed of working the two dynamos in parallel is possible, but would be costly to carry out, and not eminently successful in operation. In order to understand what connections are necessary, and why the working would not give the best results, it will be advisable to consider the necessary equipment for working two compound dynamos under normal conditions in parallel. Fig. 1 shows the ordinary connections for running two compound dynamos in parallel. The connections are as follows: positive or negative terminals of both dynamos are directly connected to one 'bus bar; the corresponding compound terminals are connected to the other 'bus bar, a switch, S S^1, being inserted in each lead, while, lastly, the two machines are further connected by a lead joining together the brushes not directly connected to the 'bus bars, a switch being inserted in this lead. This lead is shown in the figure by the line *h h*. Suppose, first of all, that this lead is omitted when the machines are both running in parallel, the currents in the various parts will flow in the direction shown by the arrows, but let dynamo A slow down, motoring of this machine will at once take place, and it is easy to see that the current will flow through the series turns in the wrong direction, and so reverse the polarity of the magnets. In order to prevent this, the equalising bar, *b b*, is inverted; the resistance of this must be negligible compared with the resistance of the compound coils of either machine. The reason of this is obvious: in case current flows from one machine to the other, it must be made to flow along this equalising bar, and not through the 'bus bars, in order to prevent reversal of magnetisation.

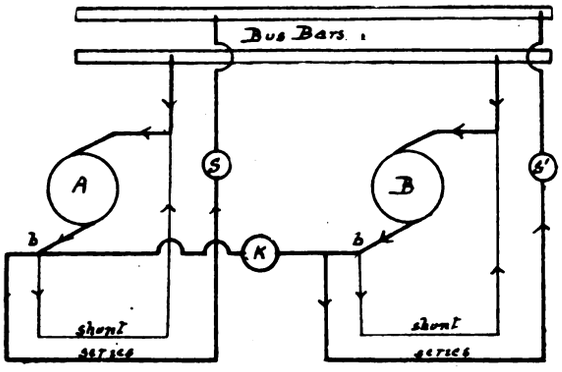


FIG. 1.

This is where the arrangement proposed will be expensive. The paralleling operation must be conducted at a switchboard. If the distance between the two dynamos is small, the leads representing the equalising bar may be comparatively light; but if the distance is 80 yards, the leads must be excessively heavy. A lead consisting of $^{61}/_{16}$'s would carry 200 amperes under normal conditions; this would have a resistance of 0·0095 ohm, which is a serious matter in paralleling operations. Assume that the resistance of the series turns on one machine is ·002 ohm, then the resistance of the circuit through these coils and the 'bus bars is 0·002 + 0·0095 = 0·0115 ohm; while through the equalising bar the resistance is 0·0095 ohm; or the ratio is as 100 : 82. Under these circumstances the resistance of the equalising bar is not negligible, and a heavier cable, say a $^{91}/_{13}$, having a resistance of 0·0032 ohm for 80 yards, must be used; this will greatly affect the cost, and even this size of cable errs on the light side, as the ratio of the two paths is then as high as 100 : 36.

Supposing, however, that this is done; if dynamo A is running, and it is required to switch B in in parallel, the switches K and S^1 must be open and the dynamo run up to the same voltage as that generated by A, switch K must then be closed, and afterwards switch S^1. To withdraw B from parallel the operation must be reversed. Assuming that B is the large dynamo, what will be the result of so working? In the first place, you can't have two machines—one at 200 volts and the other at

Digitized by Google

250 volts—working in parallel, and, therefore, the voltage of B must be brought down to 205 by means of a shunt resistance. As long as the load is steady the machines will run satisfactorily, but as soon as the load varies, owing to the bad governing of the engine driving B, the trouble will begin. If one machine slows down, the other takes an undue share of the work, and assists in driving the slow machine as a motor, thus speeding it up (1) by lightening its load, and (2) by assisting in its driving. Under standard conditions this will so adjust matters that no difficulty arises, but with B having an irregular drive, if the load is largely altered there is a great probability of the two machines not properly adjusting themselves to the new conditions and one machine becoming grossly overloaded, and so blowing the fuses.

To sum up the matter: if a heavy equalising bar (or rather equalising lead) is put in, the two machines will with steady loads run satisfactorily in parallel, but not well with a variable load unless the engine driving B is made to govern properly. Though, perhaps, apart somewhat from the question, the writer does not see the advantage of paralleling the dynamos; probably each has at present its own circuit, and it is very easy to arrange these so that either or both circuits may be supplied from one or other machine at will. All that is necessary is to bring a pair of leads from each dynamo to each switchboard, and to connect the 'bus bars of each switchboard to either machine at will by means of a two-way double pole switch, as shown in Fig. 2, which diagrammatically shows

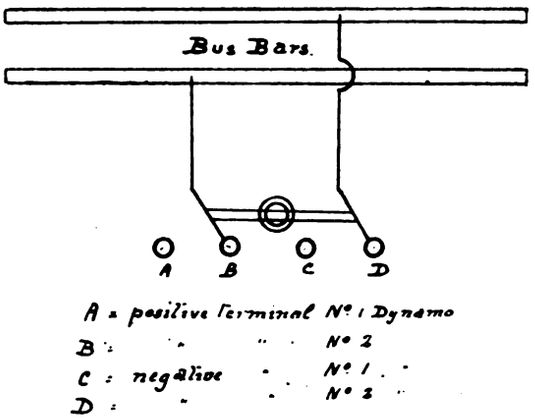

FIG. 2.

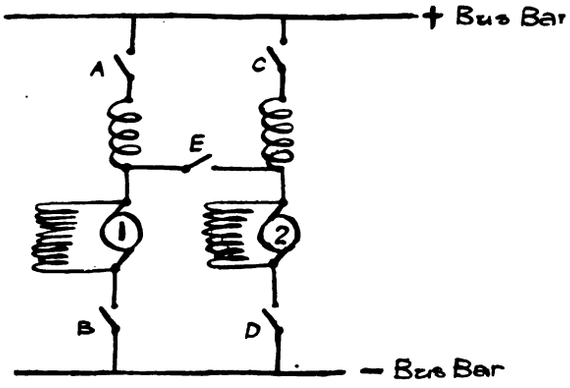
the arrangement of either switchboard. With such an arrangement there will be no danger of putting the machine in parallel, while all the ordinary conditions of working will be met.—M.

Answer to No. 486 (*awarded* 5*s.*).—The question proposes something which in ordinary practice could not be done. Two compound machines which have to run in parallel must be specially designed to do so. They must have the same characteristic—that is, their total volts at the same proportion of full load in each must be the same. Further, the resistances of armature and series must in the two machines be inversely proportional to the outputs, so that at the same proportion of full load in each the volt drop in armature and series may be the same, and thus the terminal volts would be the same. This would ensure the two dynamos taking up the load at a rate proportioned in each to their total possible output. If this does not happen to be so, then trouble arises. Suppose, for instance, that the internal resistance of the larger machine were less than would be required by the above rule; then, supposing the total volts in each to remain the same, it would take more than the correct proportion of the load to bring down the terminal volts to the same value as those of the smaller machine, and the smaller machine would be doing less than it should, until finally it would cease to give any current at all. As it is very improbable that two machines by different makers, made independently of each other, would possess the desired characteristics, it would not be advisable to run these two in parallel. A further difficulty would be caused by the bad governing of the engine, as when the volts varied by the large amount given, the dynamo would alternately be giving out no load and full load, and possibly large over-load, and if there were, as is usual, automatic minimum cut-outs at B and D, it would be the rule for these to be continually falling out. These are a necessity, for otherwise, if for any reason the volts of one of the dynamos fall so low that it gives no current, it would thereafter start to run as a motor, which is undesirable, and therefore it should be arranged that the dynamo is cut out at no load automatically.

A further reason why the dynamos should not run in parallel is because of the distance between them. In running compound dynamos in parallel, there must be an "equalising connection" between the brushes which are connected to the series winding—which must be arranged so as to be all on one pole of the machine—and this connection should be of negligible resistance. The connection is put there so as to keep the current in each series winding flowing in the same direction, and to prevent thus the reversing of the magnetism, or its abnormal weakening, if the volts of one machine fall very much, and cause it to take a reverse current. But if the resistance of the path through E is considerable, compared with the resistance of the series winding, there would in the case of any inequality be such a drop in volts along E as would make an appreciable current go along the path A C as well, and this would defeat the object of putting E in at all. Now, the resistance of a cable 60 or 80 yards long must be large compared with the resistance of a series winding, unless the cable is made so large as to be much too costly. Hence, for all three reasons named—the



dynamos being by different makers, one engine governing badly, and the dynamos being far apart—it would be most unwise to trust to their running in parallel for more than, say, five minutes without burning up.—T. C.

TRADE NOTES AND NOVELTIES.

The Premier Lamp.

The Premier Electric Lamp Company have forwarded to us an interesting little booklet which deals with the lamp manufactured in this country by them. The booklet in question is intended to educate the public in the selection of incandescent lamps, and to teach them that any judgment based on the cost alone or on the life of the lamps is absolutely useless. The Premier Lamp Company claim for their standard lamps an efficiency of 3·2 watts per candle If, however, the lamps are to be used on tramcars, the firm advocate a 3·75 watt per candle-power, on account of the arduous conditions under which these lamps have to work. The following figures as to the variation of the candle-power and efficiency of the Premier lamp, with slight variations in voltage, will be of interest, especially to those consumers who get higher voltage at their terminals than is declared by the undertakers:

Volts.	Candle-power.	Life in hours.	Efficiency.
100	16	1,000	3·2
102	17¾	680	3·0
104	20	450	2·8
106	22¼	300	2·6

The Howard Conduit.

We recently described the Howard Conduit Company's system of asphalt conduits and troughing for underground mains. We are pleased to hear that the orders for these and the accessories to be used with them are coming in well. These troughings and conduits have been, or are being, laid at the following places: Windsor, Trafford Park, Bournemouth, Nottingham, Eccles, Lancaster, etc.; and they have also secured the contract for one year's supply of their asphalt troughing from the Salford Corporation, and the whole of the troughing for the Leatherhead electric lighting scheme. The firm have just issued a new catalogue, which is worthy of careful study on the part of all mains engineers.

LEGAL INTELLIGENCE.

BOURNEMOUTH TRAMWAYS DISPUTE.

The case of the Attorney-General *v.* the Mayor and Corporation of Bournemouth was heard before Mr. Justice Swinfen-Eady in the Chancery Division of the High Court on Friday. The action was taken at the instance of the Poole and District Electric Traction Company, who claimed an injunction to restrain the defendant Corporation from constructing a certain tramway, on the ground that the statutory power of the Corporation to construct the particular tramway was determined. On Aug. 6, 1900, an Act of Parliament was passed to empower the plaintiff traction company to construct and work tramways between Christchurch and Bournemouth. On the same date an Act was passed confirming an order authorising the Bournemouth Corporation to construct tramways in their borough. One of the tramways (No. 2 in the Act) authorised by the traction company's Act was the same in position as one (No. 6 in the order) authorised by the Corporation's provisional order. But the company were prohibited from commencing at once to construct this tramway, and their right to construct it at all was to cease if the Corporation constructed their tramway (No. 6) within two years from the confirmation of the provisional orders. By the Tramways Act, 1870, Section 18, it is provided that the powers given by a provisional order to make a tramway are to determine, among other events, if within one year from the confirmation of the order, or within such shorter time as is prescribed in the same, the works are not substantially commenced. The plaintiff company contended that the Corporation had not substantially commenced the works within the prescribed period, because nothing had been done on the ground, no work had been done on the street towards making the actual tramway, and no buildings had been commenced for a generating station or other purpose in connection with the working of the tramway. The Corporation, however, had acquired a site for works and offices, and had contracted with the British Thomson-Houston Company for dynamos and machinery to be put in hand immediately by agreement actually executed April 18, 1901, and by agreement dated May 10 had contracted with the British Westinghouse Company for the supply of tramcars to be put in hand at once. Preliminary work in the preparation of plans of buildings had been also made, and steps taken to procure the necessary loan.

For the defendant Corporation, it was contended, in the first place, that as no notice of any finding of the Board of Trade had been published in the *London Gazette* of any default by the Corporation in substantially commencing works, and notice in the *London Gazette* was made by Section 18 of the Tramways Act conclusive evidence of such default, no other evidence of default was admissible.

Mr. Justice Swinfen-Eady, in giving judgment, said that in his opinion the works which had to be substantially commenced within a year from the passing of the confirmatory Act were not confined to works on the ground where the tramways were to be laid and the land acquired for generating stations and other purposes necessary to work the line. It might be desirable that the actual laying of the tramways should be postponed as long as possible, so as not to interfere before it was necessary with street traffic. However that might be, in his Lordship's judgment the works mentioned in Section 18 of the Tramways Act, and which were defined by an incorporated section of the Lands Clauses Acts as works authorised by the special Act, included the construction of machinery and works done elsewhere for the purpose of equipping the tramway. Here the Corporation had acquired land, had well within the year entered into a contract with a responsible firm of manufacturing engineers for the supply of dynamos and machinery to be constructed abroad, and had entered into a similar contract with other responsible manufacturers for the supply of tramcars. He also decided in the defendants' favour on the other point.

Judgment was accordingly entered for the defendants.

PERSONAL INJURY CLAIMS.

In the Dublin Nisi Prius Court last week, before the Lord Chief Justice and a special jury, an action was heard at the suit of George Thomas Hill against the Dublin United Tramways Company. The plaintiff claimed £1,000 damages for personal injuries alleged to have been sustained by a collision between one of the defendants' trams and a bicycle which plaintiff was riding at the time. Defendants denied that plaintiff had sustained any injuries, personal or otherwise, and pleaded negligence on the part of the plaintiff, and that the occurrence was the result of an accident.

The jury found for the plaintiff, and awarded £100 damages, and udgment was entered accordingly.

In the Liverpool County Court, on Monday, Judge Shand and a jury heard a claim by Mr. F. Hartley, a solicitor, against the Corporation for damages in respect of injuries sustained, as alleged, through being jerked off a tramcar.

The **Plaintiff** stated that on the evening of March 24 he took a Smithdown-road car at the corner of Whitechapel to proceed to his home in Chatham-street. Trusting to the car stopping at the usual station at the corner of Myrtle-street and Catherine-street, he made ready to alight, and was standing on the platform holding the upright bar. The car, however, failed to stop, upon which the plaintiff determined, in his own mind, to alight at the next stopping-place. He alleged that the car was driven round the corner in a negligent fashion, and at such a speed as to cause a considerable jerk, the result of which was to throw him into the street. Not only did he fall into a heap of mud, but sustained some laceration of the face, as well as injuries to his wrist and leg. He claimed £30 as damages for the injuries, and, in addition, the sum of seven guineas, the amount of his doctor's bill.

The jury returned a verdict in favour of the plaintiff for the amount claimed.

UNLICENSED CAR DRIVERS.

At the Liverpool City Police Court this week, Fred H. Kent, tram conductor, was summoned by the Corporation for having on the 6th inst., without lawful license, driven an electric car in Walton-vale so as to endanger the lives of persons; and Wm. Anderson, tram driver, was summoned for aiding him in the same without a lawful excuse.

Mr. E. C. Sanders, who prosecuted, stated that the defendant Kent was up to recently a conductor on the Corporation electric cars. He had been off duty for some weeks, and had been told by his doctor that it would be better for his eyes if he was a driver instead of a conductor. Before a person was allowed to drive, it was necessary to get a permit from the general manager. On the day named he asked a driver on this route to let him drive, but was refused, as he had no permit. In the other instance, Kent represented that he had a permit, and on this the driver allowed him to operate, but shortly afterwards stopped him.

The Bench characterised it as a serious case, and fined Kent 40s. and costs, and Anderson 5s. and costs.

A STREET-BOX EXPLOSION.

Before Judge Addison, K.C., in the Southwark County Court on Monday, Elizabeth Ruler, a married woman, sued the Mayor and Corporation of Southwark to recover damages for personal injuries sustained by her on April 1 by an explosion, which it was alleged was brought about owing to the negligence of the defendants in the control of certain electric wires and cables.

Mr. Drury, for the plaintiff, stated that on the night of April 15, at about half-past nine o'clock, she was at the corner of Long-lane and Great Dover-street, Borough, when suddenly she saw a very bright light, heard a noise, and was knocked down. At the same time the cover of an electric light street box was projected through the air. The plaintiff endeavoured to rise, but she fell again, and did not remember anything more until she found herself in bed at her home some time later. She had not been able to do any work since, and the doctor considered that it would be unwise even for her to go out alone. There was no dispute that the electric cables belonged to and were controlled by the Borough Council, and therefore all he had to do was to show that the accident happened, the onus being upon the defendants to show that it resulted from causes over which they had no control.

At the conclusion of the evidence the case went to the jury on the point as to whether the plaintiff had made out her case in regard to the accident to her.

After a short deliberation the jury found for the defendants, and his Honour gave judgment accordingly with costs.

SUNDERLAND TRAMWAYS CASE.

Before Judge O'Connor in the Sunderland County Court, John Elrick, builder and contractor, sued the Mayor and Corporation of Sunderland for £29. 11s. 4d. damages to his horse and cart sustained in a collision with an electric car in October last.

The Corporation admitted liability for the accident, the only question being the damage sustained by the horse, and eventually his Honour found for the plaintiff for £22. 3s. 10d.

COMPANIES' MEETINGS AND REPORTS.

ELECTRICAL POWER DISTRIBUTION.

The general meeting of this Company was held at Hamilton House, Victoria-embankment, on Monday, Mr. Emile Garcke presiding.

In moving the adoption of the report, the **Chairman** referred first to the paragraph which dealt with the offer made by the British Electric Traction Company. He explained the circumstances which led to the formation of the Company to do work which at the time was considered to be outside the scope of both the British Electric and the Brush Companies. The initial risks and responsibilities were undertaken by himself and three other directors. They received 200 deferred shares, for which they paid cash, but which were entitled to certain rights after a very ample dividend had been paid. When it was found that the existence of those shares was a bar to the raising of necessary additional capital, an agreement was arrived at that the Company should have within 10 years the right of extinguishing the special privileges attached to those shares by the payment of £10,000 in cash. This was the position when the British Electric and the Brush Companies decided to take a large interest in the Company's further development. The terms offered were recommended as fair and impartial. As managing director of one company and chairman of the other, he had received a few protests from shareholders in each company, complaining that their respective companies had not been fairly treated. The shares of the Electrical Power Company cost the shareholders £11 each, both ordinary and preference. The shareholders were under the scheme to exchange an ordinary share for a British Electric share, which now stood in the market at £14, and they were asked to exchange a preference share for a British Electric preference share, which now stood in the market at about £12¼. The offer which the British Electric Company made to the Electrical Power Company left the matter open for each share holder to accept or decline. If he did not accept the exchange of shares he would be in a still smaller minority than he was at present.

Digitized by Google

The British Electric Company and the Brush Company held 14,000 out of the 15,000 ordinary shares, and about half the preference shares in the Electrical Power Company. The latter possessed Acts of Parliament to carry on work in an important industrial centre in the county of Durham and in North London. They possessed 17 electric lighting and three tramway and light railway orders, while three provisional orders had received the sanction of the Board of Trade, but were awaiting parliamentary confirmation. In the short time they had been at work they had erected eight electrical power stations in various parts of the country.

Mr. W. L. Madgen seconded the motion, which was adopted.

CHADBURN'S (SHIP) TELEGRAPH.

The annual general meeting of shareholders in the above Company was held at Liverpool on Friday, Mr. William Chadburn presiding.

The **Chairman,** in moving the adoption of the report (*vide* last issue), said it would be noticed that the profits available for dividend, £8,765, were somewhat less than at the end of the previous year. The shareholders would remember that at the last annual meeting he had intimated this would probably be the case, and explained the reason, which was that in last year's accounts it had happened that a good many contracts had been completed just in time to bring the profits within that year's accounts. During the past year this had not been so fully the case ; but he was happy to assure them that the business as a whole was quite as satisfactory as when they met last year, and, indeed, the auditors, who had gone most exhaustively into the position of the Company, reported that the year just ended was as good as any previous year. Under the circumstances the directors felt justified in paying a dividend at the same rate as last year. Since the close of the year a number of contracts had been completed, some for large ships representing a considerable amount of money, but those could not be brought into last year's accounts. They would, however, come into the next accounts

Mr. J. Orford seconded the motion, which was carried.

BRITISH ELECTRIC TRACTION.

The ordinary general meeting of the shareholders of the above Company was held at Hamilton House, Victoria-embankment, on Monday, Sir Chas. Rivers Wilson presiding.

The **Chairman,** in moving the adoption of the report (which will be found in our last issue), remarked that the business of the Company had extended in almost every direction. Notwithstanding the larger capital on which they had had to pay, they had maintained the dividend at 9 per cent., and had increased the carry forward by about £6,000. With regard to their 55 undertakings, it would be seen that full details of them were published in the report, and the Board did all in their power to place before the shareholders the fullest information concerning the operations of the Company. Concerning the schemes in hand, the most important was that in connection with the electrification of the North Metropolitan Tramway Company's system, together with the light railways in the North of London. That scheme was one of the largest which had ever been contemplated, and when completed they would have 130 miles of electric tramways in the North of London. Referring to the arrangements with the Brush Company and the Electric Power Distribution Company, the Chairman said that some of the shareholders might hold the opinion that the capital was being increased too quickly. Still the new business which the Company was developing was of a very profitable character, as was shown by the fact that they were not only increasing their traffic receipts, but also the receipts per mile. They were earning a larger net profit on a larger capital. The Board proposed to increase the capital by £1,000,000 in ordinary shares and £1,000,000 in preference shares, which would give them the power to issue £1,000,000 debenture stock and so double the existing capital. It was proposed to issue 20,000 shares to the present shareholders, and that distribution would be in the nature of a bonus, as they would be allotted at par. There had not been an increase in the dividend, though the profits had advanced, and the directors thought it right, therefore, that the shareholders should have the advantage of the new allotment of shares at par, and they had arranged that coupons for fractions of shares should be issued in order that the small shareholders should have the advantage of the new shares.

Mr. Emile Garcke seconded the resolution, which was put and carried unanimously.

On the motion of the **Chairman,** a resolution for the increase of the capital of the Company from £2,000,000 to £4,000,000, divided into 400,000 shares of £10 each, by the creation of 200,000 new shares of £10 each, was also carried unanimously.

The retiring directors (Mr. C. Shirreff B. Hilton and the Hon. Sir Charles W. Fremantle) were re-elected, and the meeting terminated with a vote of thanks to the chairman and directors.

PERTH ELECTRIC TRAMWAYS.

Presiding over the ordinary general meeting of this Company at 3, Laurence Pountney-hill, on the 12th inst., **Mr. E. Heasman** congratulated the shareholders on the progress made by the undertaking. For the first three months of the year seven miles of lines were in operation, and this was ultimately increased to 13 miles, the average mileage being 11½ in the period. The total revenue earned was £60,268, representing average receipts of over £67 per mile per week. For the first 21 weeks of 1902 the average gross earnings per mile per week were over £68. With the increasing prosperity of the city of Perth, the Board felt certain that the undertaking would continue to be very valuable. The working expenses showed a satisfactory ratio o the receipts, being a little over 60 per cent. for the period under review. This ratio of expenses was applicable to different sections of comparatively short mileage. The present average ratio of working expenses for the first 21 weeks of the current year was only 52·6 per cent., and therefore as the traffic increased it was only reasonable to suppose that a greater reduction in this respect might be looked for. The growth of traffic necessitated addditional rolling-stock and motive power. For this purpose, and for the construction of further sections, the Board had spent £102,109 on capital account during the 18 months under review. The Board had issued £169,197 of the 5 per cent. first mortgage debenture stock out of the authorised issue of £200,000, and after providing for the interest on this amount up to Dec. 31 last, and for the interest on loans and for trustees' fees, the Company had a balance of £7,354 standing to the credit of profit and loss account. At the end of June, 1900, they had a balance on the debit side of profit and loss account amounting to £2,957. At Dec. 31 last this debit balance was wiped out, and £4,396 remained available for distribution. The dividends on the preference shares at the rate of 6 per cent. per annum, which had accumulated since the date of their issue up to the end of 1901, amounted to £5,921, and the Board now proposed to pay off this amount. There would then be a balance of £1,124 to be carried forward. He concluded by moving the adoption of the report.

The motion was seconded by **Mr. R. C. F. Ogilvie,** and adopted.

BRUSH ELECTRICAL ENGINEERING.

The following has been published by Mr. Broadhurst, the secretary and assistant manager of the above Company : "The Brush Electrical Engineering Company, Limited, have received an offer from the British Electric Traction Company, Limited, for an exchange of shares in the following proportions: one fully-paid £10 ordinary share of the British Electric Traction Company for 10 £2 fully-paid ordinary shares of the Brush Electrical Engineering Company ; one fully-paid £10 preference share of the British Electric Traction Company for six £2 fully-paid preference shares of the Brush Electrical Engineering Company, Limited. A circular communicating this offer to the shareholders of the Brush Electrical Engineering Company will be issued at once."

KALGOORLIE ELECTRIC LIGHTING AND POWER.

The report of the directors covering the period from Oct. 1, 1900, to Dec. 31, 1901, states that the contract with J. G. White and Co., Limited, electrical engineers and contractors, for the erection of a complete electrical power transmission plant will soon be completed. The time for the completion of the contract was July 29, 1902, but such excellent progress has been made that the directors were enabled to supply power to the Kalgoorlie Electric Tramway Company on May 1. The shareholders have already been informed of the contract entered into with that company for the supply of power for 10 years. The tramway was formally opened to the public on May 20. Enquiries have been received from users of power for more than double the amount at the Corporation's disposal. These are now being carefully considered by the Corporation's representatives in Kalgoorlie with a view of entering into such contracts as will be most advantageous to the Corporation. Further capital being necessary for subsidiary machinery, including rotary transformers, motors, hoists, pumps, etc., the directors, under the powers given to them by the articles of association, have created an issue of £50,000 6 per cent. debentures, of which a portion has been placed.

ELECTRIC AND GENERAL INVESTMENT.

The directors of this Company recommend the following dividends for the year ended May 31 : on the ordinary shares a dividend of 5s. per share, of which 2s. per share was paid on account in December last, leaving 3s. per share to be distributed, and a bonus of 2s. per share. The trustees for the ordinary shares' reserve fund propose to distribute out of the proceeds of investments sold and dividends received 1s. per share, making a total present distribution of 6s. per share, or 30 per cent., or a total distribution of 8s. per share, or 40 per cent. for the year. Founders' shares, a dividend for the year of £50 per share. The trustees for the founders' shares reserve fund propose to distribute out of the proceeds of investments sold and dividends received £10 per share, making a total present distribution of £60.

CALLENDER'S CABLE AND CONSTRUCTION.

The report of the directors for 1901 states that the accounts show a balance at the credit of profit and loss for the year's working of £71,978, to which must be added £10,855 brought forward from 1900, making together £82,833. From this must be deducted : interest on calls paid in advance, £28 ; interest on debentures, £4,050 ; dividend on preference shares, £10,000 ; appropriation for depreciation of plant, machinery, and furniture, £7,134 ; carried to machinery renewal fund, £3,000 ; leaving an available balance of £58,621. The directors propose a dividend to the holders of ordinary shares, Nos. 1 to 30,000, at the rate of 10 per cent. per annum, clear of income tax, being 10s. per share, whereof 5s. was paid on Nov. 1, 1901, and 5s. on Saturday, £15,000 ; a bonus of 5s. per share, £7,500 ; further payment of a special bonus of 5s. per share, £7,500—carried forward, £28,621. The total payment to the holders of the first 30,000 ordinary shares in respect of 1901 will, therefore, for dividend and bonus be 20s. per share. The business transacted during the past year was once again in excess of that of all previous periods. The directors state that, in spite of the keen competition in all branches of the Company's trade, the factory is now fully employed. The following circular is appended to the report : "We regret to say

Digitized by Google

that certain differences have arisen between the Company and W. T. Henley's Telegraph Works Company, Limited, as to the terms of the proposed amalgamation, which, in the opinion of both Boards, render it impracticable—at any rate, for the present—and the negotiations have, therefore, by mutual consent been treated as at an end."

NEW COMPANIES REGISTERED.

Thornton and Atkinson, Limited.—Capital, £3,000. Objects: to carry on the general business of engineers and metal founders of H. and A. R. Thornton at the Providence Foundry, Cleckheaton, Yorkshire, and also that of J. N. Atkinson, at Boro' Mills, Bradford, Yorkshire, under the style of the Bradford General Electric Company, etc.

Clubbe and Southey, Limited.—Capital, £2,000. Objects: to acquire and continue the business of A. W. Southey, and to acquire and turn to account certain patents; as mechanical, general, electrical, and mechanical engineers, builders and owners of electrical vehicles of all kinds, etc.

Hanson-Walsh Engineering Company, Limited.—Capital, £5,000. Objects: to acquire as a going concern the business of engineers of J. T. Hanson at Parkwood Mills, Longwood, Yorkshire, and to carry on business as manufacturers of machinery of every description, as electricians and electrical engineers, manufacturers of wires, cables, dynamos, and all apparatus used in connection therewith, etc.

Chloride Electrical Storage Syndicate, Limited.—This Company have changed their title into Chloride Electrical Storage Company, Limited.

Motor Manufacturing Company, Limited.—Capital, £80,000. Objects: to adopt an agreement with a company having a similar title, and generally to carry on business as ironfounders, electric and water-supply engineers, etc.

Scottish Automobile Company, Limited. — Capital, £100. Objects: to acquire inventions, etc., and to carry on the business of manufacturers of motorcars, etc.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Chester.—The Corporation invite tenders for accumulators and booster. Tenders by July 7.

Shanghai.—The last day for receiving tenders for the proposed municipal tramway and motor 'bus service is June 30.

Madrid.—The Department of Agriculture require a number of meters and instruments valued at £1,000. Tenders by June 30.

Whitworth.—The Urban District Council invite offers from firms willing to provide a service of electrical trams in Whitworth. See advertisement.

Sunderland.—The Corporation invite tenders for the supply of permanent way, overhead equipment, and cables. Tenders by July 9. See advertisement.

West Ham.—The Council invite tenders for 50 double-deck electric tramcars, complete with electrical equipment. Tenders by July 8. See advertisement.

Romford.—The Urban District Council invite tenders for the construction and maintenance of electricity supply works in the district. Tenders by June 30. See advertisement.

Valparaiso.—The Municipality are inviting tenders for electric lighting and tramways. We understand that particulars may be obtained from the Chilian Consul. Tenders by Sept. 1.

Bury.—The Tramways Committee invite tenders for the supply and delivery of rails and fishplates, fishbolts and nuts, tiebars, points and crossings, and sole or anchor plates. Tenders by June 24.

Leskovatz (Servia).—The Société d'électricité de Leskovatz require two turbines of 200 h.p. and two dynamos for three-phase current; also accessories for a power installation with a radius of 11 miles. Tenders by July 1 (14).

Bexley.—The Urban District Council invite tenders for points and crossings and boilers. Specifications, etc., may be obtained from the engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, Westminster, S.W. Tenders by July 7.

Lowestoft.—The Corporation invite tenders for the construction of tramways, rails, fishplates, and bolts, and permanent-way construction. Specification, etc., may be obtained from Mr. R. Beattie Nicholson, town clerk, Lowestoft. Tenders by July 12.

Launceston (Tasmania).—The Corporation invite tenders for polyphase generating, transmitting, and distributing plant and apparatus, transforming apparatus, reconstruction of existing plant, and enclosed arc lamps and accessories. Tenders by Sept. 15. See advertisement.

Willington Quay.—The Willington Quay and Howdon Industrial Society, Limited, invite tenders for supplying and fixing electrical apparatus as required for power and light at their Bewick-road premises. Specification, etc., can be had on application. Tenders by noon on July 4.

Falkirk.—The Corporation invite tenders for storage batteries, generators, transformers, switchboard, cable work, crane, lamps, and fittings. Specifications can be inspected at Messrs. Burstall and Monkhouse, 14, Old Queen-street, Westminster. Tenders by July 14. See advertisement.

Kirkcaldy.—The Corporation invite tenders for wiring the central station. Specification, etc., can be obtained from Mr. Wm. L. Macindoe, town clerk, or seen at (but not obtained from) the office of Messrs. Kennedy and Jenkin, 17, Victoria-street, Westminster, S.W. Tenders by 21st inst.

Gillingham.—The Urban District Council invite tenders for the supply and erection of two water-tube boilers, steam and exhaust piping, condenser, cooling tower, high-speed engines, three triphase alternators (250 kw. each), switchboard, underground cables, arc lamps, crane, and well. Tenders by July 17. See advertisement.

Ipswich.—The Corporation invite tenders for the supply, delivery, and erection at the generating station, Constantine-road, Ipswich, of engines and dynamos, storage battery, overhead hand travelling crane, feeders, mains, and road work, permanent-way construction of tramways, and arc lamps. Tenders by July 5. See advertisement.

London, S.W.—The London County Council invite tenders for the supply, delivery, and erection at the Council's temporary generating station at Loughborough Junction of steam, exhaust, feed, and other piping, valves, etc. Specifications and other particulars may be obtained from the County Hall, Spring-gardens, S.W. Tenders by July 8.

Epsom. The Urban District Council invite tenders for the supply and erection of semi-marine dry-back boiler, with fittings, etc.; ejector condensers, circulating pumps, and pipework; spray cooling pond; steam, feed, and drain pipes, etc.; and one 150-kw. steam dynamo (vertical enclosed high-speed engine) and switchgear, etc. Tenders by July 18. See advertisement.

Nuneaton and Chilvers Coton.—The Electricity Committee invite tenders for the supply and delivery of private lighting cables (paper), public lighting cables (rubber), joint-boxes and compounds and 20 arc lamp columns, with incandescent brackets, complete with arc and incandescent lamps, cut-outs, switches, resistances, and all other accessories. Tenders by June 30.

Bury.—The Tramways Committee invite tenders for the work required in the construction of the permanent way in several parts of the borough—viz.: Fairfield section, Bolton-road section, Heywood-street and Knowsley-street sections. Specifications, etc., can be obtained on application at the office of Mr. Arthur W. Bradley, borough engineer and surveyor. Tenders by June 24.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramways and Electricity Board invite tenders for the supply, delivery, erection, and construction of three 500-kw. steam-driven, direct-coupled three-phase alternators, etc.; three 50-kw. steam-driven, direct-coupled continuous-current exciters, etc.; and permanent way, including copper bonding and conduits for cables. Tenders by July 7. See advertisement.

Toddington.—The Urban District Council having obtained a provisional order enabling them to supply electricity within the urban district of Toddington, invite tenders from persons and companies able to carry out electrical undertakings, stating terms upon which they would be willing to take over such provisional order, and to submit a scheme of electric lighting for the district, with particulars of cost. Tenders by July 12. See advertisement.

Sydney (New South Wales).—Messrs. Preece and Cardew are authorised by the Municipal Council of Sydney, New South Wales, to invite tenders for supply, delivery, laying, and erection of a complete system of high and low pressure cables, and of arc lamps for street-lighting. The contract will include cast-iron pipes, wood troughs, high and low pressure cables, joint-boxes, frames and covers for street boxes arc lamp-posts and brackets, arc lamps, controlling gear, telephone instruments, etc. Tenders must include the whole of the material laid and erected complete. Tenders for a portion only of the work will not be considered. Copy of the specification, general conditions, and form of tender may be obtained from Messrs. Preece and Cardew on payment of a deposit of £5, which will be refunded on receipt of a bona fide tender and the return of the specification and general conditions. A duplicate copy of the specification and general conditions can be obtained on payment of £1. Sealed tenders, endorsed "Sydney Electric Lighting," are to be addressed to Messrs. Preece and Cardew, and delivered at their offices, 8, Queen Anne's-gate, Westminster, London, S.W., before 12 noon on 23rd inst.

RESULTS OF TENDERS.

Oban. The tender of A. and J. Stewart and Menzies, Glasgow, has been accepted for cast-iron pipes for carrying the cables.

Natal-Durban Railway.—Messrs. D. Bruce Peebles and Co., Edinburgh, have secured the tender for the electrical generating plant in the Government railway shops, at £8,371.

Portsmouth.—The Town Council have decided to purchase 310 electricity meters from the Newcastle-on-Tyne Electric Supply Company, at £600.

Dundee.—Messrs. Willans and Robinson have received an order through Messrs. Dick, Kerr, and Co. for one 1,200-h.p. triple-expansion engine for the Corporation.

Guildford.—Messrs. Willans and Robinson have received an order from the Electric Light Company for a 240-h.p. compound engine for direct coupling to a Newton dynamo.

Canterbury.—The Town Council have accepted the tender of E. J. Philpot, at £25, for wiring the Beaney Institute, according to design submitted for illumination on Coronation Day.

Central London Railway.—This company have accepted the tender of the British Thomson-Houston Company for equipments for 64 motorcars and 160 trailers. Details appear in another column.

Manchester.—The Tramways Committee of the Corporation have just placed an order for 34,000 copper railbonds with Messrs. Robert W. Blackwell and Co., Limited, 59, City-road, London, E.C.

Digitized by Google

Metropolitan District Railway.—The contract for a switchboard to control the 10,500-kw. 11,000-volt generators and other accessories for the generating station of this line has gone to the British Thomson-Houston Company. Details of the plant appear in another column.

London County Council.—The Historical Records Committee have received the following tenders for the supply and fixing of a special battery in connection with the emergency electric light installation at the Horniman Museum: Pritchetts and Gold, £66. 4s. (accepted); Chloride Electrical Storage Syndicate, £73. 5s.; Electrical Power Storage Company, £76. 8s.; Drake and Gorham, £83.

General Post Office.—Messrs. Willans and Robinson have received an order from the General Post Office for four 250-h.p. compound engines for direct coupling to Siemens dynamos for the General Post Office Savings Bank, West Kensington. They have also received an order for two 360-h.p. engines for direct coupling to dynamos by Dick, Kerr, and Co. for the telegraph factory, Mount-pleasant.

Walsall.—The Town Council have accepted the following tenders: Babcock and Wilcox, supplying and erecting one of their water-tube boilers, with fittings and superheater, £1,080; Electrical Power Storage Company, supplying and erecting a battery of accumulators, £1,117. 16s.; Walsall Electrical Company, for the wiring for the lights at the Hospital-street sub station, for wiring the casing for the cables for the machines, and for supplying and fixing a telephone, £30. 3s. 4d.

BUSINESS NOTES.

TRACTION.

Naples.—The employés of the tramway company here have gone out on strike.

Yarmouth.—The new electric tramway was officially inspected on Wednesday.

Govan.—The Social Democratic Federation are agitating for cheaper fares on the tramcars.

Hipperholme.—It is proposed to extend the electric lighting and tramways from Stump Cross to Hipperholme.

Whitworth.—The District Council are advertising for offers of parties desiring to run electric trams into the district.

Brighton.—The members of the Electric Tramways Committee have decided to visit Norwich to inspect the tramways in that town.

Huddersfield.—The electric cars have commenced running on the Birkby section of the Corporation tramways to Almondbury and Honley.

North Somerset.—A proposal is on foot to construct a light railway through certain parts of North Somerset, commencing at Clutton.

Prestwich.—The negotiations between the District Council and the Salford Corporation are proceeding successfully with reference to the tramways.

Stroud.—The Light Railway Commissioners have arranged to hold a local enquiry into the proposed light railway scheme some time before August.

Croydon.—The Town Council have decided to oppose the application which has been made for powers to construct a light railway from Dulwich to the Crystal Palace.

Barrow.—A special meeting of the Town Council has confirmed a resolution of the General Purposes Committee to lease the tramways to the British Electric Traction Company.

Maidstone.—The Rural District Council have decided not to oppose the proposed tramways from Maidstone to Barming, but the scheme is being opposed by a body of ratepayers who do not welcome the proposed line.

Buxton.—The several schemes which have been placed under the notice of the respective local authorities for constructing a light railway from Grindleford Bridge to Bakewell have not so far taken any definite shape.

Harrow.—A special meeting of the Council has decided to oppose the new scheme for the construction of a light railway through the district unless protective clauses are inserted in the order to meet the wishes of this Council.

Adelaide.—Every preparation is being made by the Westinghouse Company for the introduction of electric tramway traction into Adelaide, Australia. The necessary plans and designs for the laying of the lines are now being drawn.

Colne.—In regard to the Colne and Trawden light railway, it is stated that the promoters have agreed to the conditions named by the Council. There is every reason to believe that the company intend to proceed with the building of the railway.

Subways in the City.—An agreement for the construction of a subway between the stations of the Central London Railway and the City and South London Railway in front of the Mansion House has received the approval of the Common Council.

Exeter.—The Exeter and District Tramways Bill, conferring additional powers on the Exeter and District Tramways Company (but not for lines within the borough), has passed the preliminary stages of the House of Lords, and is ordered for third reading.

Hindley.—The Urban District Council are considering an offer from the South Lancashire Tramway Company to lease the present tramway from the Council if purchased by them, and to apply for necessary powers to the Board of Trade as to alteration of gauge, etc.

Bath.—Sir Frederick Bramwell is conducting an arbitration at the Surveyors' Institute, Westminster, as to the price to be paid by the Bath Corporation in the compulsory purchase of the tramway undertaking of the Bath Road Car and Tramways Company, Limited.

Chatham.—The Chatham and district electric tramways were opened on Monday by the Mayor. The line was constructed under a light railway order by a syndicate of capitalists incorporated under the Companies' Act. The capital of the undertaking is £50,000.

Ashby.—At the last meeting of the Council the hope was expressed that the light railway scheme would receive the fullest consideration, since it affected Ashby very much more than the previous one, the suggested route going through a very important part of the town.

Doncaster.—The Corporation are pushing forward the section of the electric tramway to the racecourse, and it is hoped that it will be completed in time for the Agricultural Show on July 2 and 3. Major Druitt, of the Board of Trade, has arranged to inspect the line on July 1.

Stalybridge.—The members of the Tramways Committee of the Stalybridge, Hyde, Mossley, and Dukinfield Tramways Board have decided to visit Hanley, London, Portsmouth, Southampton, and Loughborough for the purpose of inspecting various types of overhead equipment and cars.

Twickenham.—The London United Tramways Company had a trial trip over the extension of their line to Twickenham, the first part of the route from Isleworth to Hampton Court, on Wednesday. The cars will run from the Tube terminus at Shepherd's Bush, *via* Brentford and Isleworth, to Twickenham to-day (Friday).

Canterbury (N.Z.).—We understand that the agent of the British Electric Traction Company at Auckland has made proposals to the Canterbury Municipal Council to provide the city with electric tramways. The question which now arises is as to the system to be adopted. The overhead system seems to be the one most favoured at present.

Middlesex.—It is stated that the Middlesex County Council are about to commence the construction of the electric tramways, in respect of which parliamentary sanction has been obtained. The Council's Finance Committee are providing £1,000,000 for the first part of the scheme. This is exclusive of the cost of generating stations and equipment.

Isle of Thanet.—A short time ago there was a great outcry against the light railway company for running their cars at an excessive speed. Now complaints are being made at the slow speed at which the cars travel on certain parts of the route, and the Broadstairs Urban District Council have started a correspondence with the company on the subject.

Private Bills.—In the House of Lords the Birmingham and Midland Tramways Bill, the Erdington Tramways Bill and the Scarborough Tramways Bill have been read a third time, and the following a second time: Metropolitan District Railway Bill, the Wrexham District Tramways Bill, and the Croydon and District Electric Tramways Bill.

Hanley.—The Town Council have sealed a petition to the House of Commons praying for the insertion in the Bill now being promoted by the North Staffordshire Tramways Company and the Potteries Electric Traction Company of a clause empowering the local authorities affected to jointly purchase the generating stations of the company as part of their undertaking.

Burton.—It is decided to provide a shed for 20 tramcars and out-offices at the depôt in Horninglow-street at a cost of £5,750. The Council are opposed to the Midland Railway Company's application for a light railway from Ashby to Burton. An attempt is to be made to confer with the Midland Company on the matter to see if an arrangement could not be arrived at.

Portsmouth.—The Town Council have issued their annual statement on the tramway undertaking. What with the loss of traffic through reconstruction, the cheapening of the fares, and the heavy capital and sinking fund charges, a deficit has to be met. The total receipts for the year were £50,663, and working expenses totalled £29,871 £5,183 being the year's deficit.

Bilston.—Sufficient progress has been made with the tramway scheme, which is to connect Bilston with neighbouring towns, to enable some trial trips to be made. The new section runs from the Fighting Cocks, on the boundary line of Wolverhampton and Sedgley, to Bilston, but it is expected that a week or more will elapse before the Board of Trade inspection takes place.

Newcastle.—The Tramways Committee have sanctioned the purchase of £1,500 worth of tools for the repairing of trams and construction of tramcars. Eight open cars for the summer months are now ready, and will be run as soon as the weather permits. In the course of the summer other similar cars will be put on the lines, making 25. A motor wagon or repairing tower is to be purchased at a cost of about £400.

Wandsworth.—With reference to the County Council's tramway proposals, a letter was read at the last Borough Council meeting to the effect that no undertaking could be given to proceed continuously by day and night with the construction of the proposed double line of tramways across Putney Bridge. The Council decided to present a petition to the House of Lords, if necessary, with a view to obtaining the required undertaking.

Unopposed Bills.—The Chairman of Ways and Means in the House of Commons on Wednesday had under consideration the following Bills, which are now unopposed: the Tyneside Tramways and Tramroads Bill, the Northumberland Electric Tramways Bill, and the Newcastle-upon-Tyne Corporation Tramways Bill. In each case, after formal evidence had been heard, the Bills were passed and ordered to be reported to the House.

Newport (Mon.).—The Tramway Bill which the Corporation are promoting in this session of Parliament has been passed by the com-

Digitized by Google

mittee of the House of Lords of which Lord Hawkesbury is chairman, with the exception of a proposal for a short length of tramway over a level crossing. The powers thus obtained will enable the Corporation to double the existing lines, and to carry them to the borough boundary and to apply electric traction.

Southport and Lytham Tramroad Bill.—This Bill has passed Lord Brougham's Committee of the House of Lords, the preamble being proved last Friday. The object of this Bill is to extend the time limited for the acquisition of land and the completion of works under the Southport District Tramway Act, 1899, and the Southport and Lytham Tramroad Act, 1900, for authorising the issue of preferred and deferred half shares, and for other purposes.

Tyneside Tramways Bill.—The Court of Referees sat at the House of Commons on Wednesday to hear an application made by the North-Eastern Railway Company for the rehearing of their claim to be heard in committee against the Tyneside Tramways and Tramroads Bill. The Court decided not to rehear the case, the chairman stating that it would be a dangerous precedent to allow a case to be reopened simply because arguments had not been sufficiently pressed.

Manchester.—In connection with the order recently placed by the Corporation with Messrs. R. W. Blackwell and Co. for 54,000 copper railbonds, we understand that these bonds are of the well-known "Crown" and "Chicago" types, which have been used to such a great extent in this country. This order, taken in conjunction with an order placed by the Manchester Corporation last year for 50,000 railbonds, should constitute a record for railbond orders in this country.

London United Tramways.—Mr. Compton Rickett's Select Committee of the House of Commons is still taking evidence on the Bill promoted by the London United Tramways Company, who seek powers to make extensions of their system at Richmond, Kew, Mortlake, Barnes, and Hammersmith in one direction, and at Malden, Wimbledon, and Merton in another direction. So far only those lines affecting the Richmond and Wimbledon districts have been considered by the committee.

Ashton-under-Lyne.—The Council have appointed a deputation to confer with the Stalybridge and Dukinfield Tramways and Electricity Board as to the question of joint running powers. The question of constructing the proposed lines in Old-street and Scotland-street has been referred to a sub-committee for consideration. The proposed appointment of a tramway manager has also been referred to a sub-committee. Tenders are to be invited for the necessary rails for the tram shed.

Bradford.—A new experiment is being tried on one of the sections of the city tramways in the shape of overlapping 1d. stages. Heretofore the distance between Saltaire and Forster-square has been divided into two stages only—one on either side of the Frizinghall boundary. These stages are retained, but a 1d. fare is charged for the journey between the Branch Hotel and the Park gates. Should the experiment of overlapping stages prove successful, it will probably be extended to other routes.

New South Wales.—The quarterly report of the Railway and Tramway Commissioners for the term ending March shows an increase in revenue from the tramways of £21,000, the total sum amounting to £172,000. The following are the official figures for the quarter: miles open, 103½; revenue, £172,877; expenditure, £131,672; tram miles run, 2,244,851; earnings per tram mile, 1s. 6½d.; expenditure per tram mile, 1s. 2d.; percentage—expenditure to earnings, 76·17; number of passengers carried, 28,624,112.

Shields.—The North and South Shields Electric Railway Bill, to which there is now no opposition, was under the consideration of the Chairman of Ways and Means in the House of Commons on Wednesday. By the provisions of this Bill the promoters will be enabled to carry into effect a scheme for uniting North and South Shields by means of an electric railway carried in a tunnel beneath the river. After evidence of a formal character had been heard the Bill was passed, and was ordered to be reported to the House.

Southport.—At the last meeting of the Town Council it was stated that the Corporation tramways were 7¾ miles long, apart from those leased. The passengers carried last year numbered 3,318,000, and the average fare per passenger was 1·13d. Suggestions had been made from time to time that the Council should adopt a universal 1d. fare, but experience had shown that a 1d. fare was only suitable in a central zone, where passengers were constantly getting in and out. Outside that zone, where passengers were fewer, the 1d. fare would be a decided loss. The gross profits amounted to £6,569, which was equal to 6½ per cent. on the capital outlay.

Nottingham.—A trial was on Monday afternoon made of the Sherwood-rise route, which was completed a short time back. By this line a connection has been established between the Sherwood and Bulwell sections. Residents on the western side of the city will, under the new arrangements, be enabled to join the Sherwood-rise cars at Basford Midland Station, and come straight through to Station-street without changing. The trial was attended with excellent results, both the line and the overhead equipment being found entirely satisfactory. The date of the Board of Trade inspection has not yet been fixed, but it is not expected to be long delayed.

Dundee.—At a meeting of the Works Committee on Monday it was pointed out that the laying of the permanent way for the Constitution-road tramway, for which the time limit expired that day, had not yet been completed. The burgh engineer explained that an allowance was generally made in respect of bad weather. Several members said that, while they might not be willing to impose the contract penalty, they thought the work had been undesirably protracted, and one member suggested that the contractor should be asked to meet the committee and explain the cause of the delay. It was, however, agreed to leave the matter to the Tramways Committee to be dealt with.

Plymouth.—Major Pringle, Board of Trade inspector, has inspected the short length of line connecting the Corporation tramways with the Plymouth, Devonport, and Stonehouse Company's system at Derry's Clock, and passed it for traffic. Under their agreement with the Plymouth and Devonport Company the Corporation have power to run cars over the company's line as far as the borough boundary, and the connection between the two systems has been made with the object of running a through service of cars from one end of the borough to the other. Plans have been prepared for the construction of a terminal line at the Octagon, but the work, which will necessarily take some time, has not yet been commenced.

Surrey.—The City and Surrey Electric Railway Company have acquired a City terminus for their proposed tube in King William-street, and a working agreement has been entered into with the South London Company for the joint use of their tunnel under the Thames. Starting from King William-street, the route proposed is parallel to that of the existing South London line to a point a little south of the Borough Station, then branching westward through St. George's-circus by Lambeth, Kennington, the Oval, and Lorn-road to Brixton. From there the line will pass through Streatham, Norbury, Thornton Heath, and Croydon to Warlingham. One branch then proceeds east to Westerham, and the other west to Redhill and Reigate.

Metropolitan Railway.—It is reported that an arrangement has been concluded between the Metropolitan and Great Western Railway Companies whereby the forthcoming electrification of the former line will be extended over the joint line of the two companies as far as Hammersmith, so as to give the electrical trains of the Metropolitan a through run between Hammersmith and the City. The electrification of the Metropolitan route is being pushed forward with all possible speed now that all difficulties with the Great Western Company have been overcome. Another important improvement will be the enlargement and remodelling of Baker-street Station, which will greatly facilitate the working both of the main line and circle trains of the Metropolitan Company.

Hyde.—It is announced that the laying of the rails for the Gee Cross tramway scheme is to be commenced almost immediately. This scheme will complete a continuous service of electric trams between Hyde and Stockport *vid* Bredbury. To proceed with the scheme an agreement was required between the Corporations of Hyde and Stockport, the Bredbury and Romiley Urban Council, and the Oldham, Ashton-under-Lyne, and Hyde Electric Tramways Company. After much delay the agreement has been signed, and the Stockport Corporation have just extended their tramways for a distance of about 400 yards to the Bredbury-Hyde boundary. It has been arranged that the tramways company shall carry out the Gee Cross scheme, which is a little over a mile in length, and is expected to cost about £8,000.

Cavehill and Whitewell Tramways Bill.—Notwithstanding the vigorous opposition of the Belfast Corporation, the above measure has succeeded in passing through committee both in the House of Commons and in the House of Lords. In the latter case the preamble of the Bill was passed before Lord Newton's Select Committee last Monday. The Bill empowers the tramway company to lease the lines to the British Electric Traction Company, who will immediately proceed to apply electric traction to the same. The opposition of the Belfast Corporation was based on the ground that as they will in time to come acquire and electrify the street tramways in the city they should also control the lines outside the city, and thus be able to give an uninterrupted service to Whitwell by connecting up the two systems.

London County Council.—The County Council have decided to appoint a distribution engineer, at a salary of £350 a year, on the electricity staff of the tramways department. In order to carry out the duties of the position, the Highways Committee are of opinion that the person appointed should have had experience (*a*) in the actual manufacture and laying of electric cables on various systems, (*b*) in the theory and practice of electric testing, (*c*) in the locating and repairing of faults, and (*d*) he should also be accustomed to the charge and control of men. The Highways Committee at the usual weekly meeting of the Council on Tuesday asked for authority to expend £2,700 on the acquisition of a site in Brixton-road for the erection of a transformer station in connection with the electric tramway scheme.

Wellingborough.—Difficulty has arisen in connection with the Wellingborough and district tramways scheme over the route between Higham Ferrers and Irthlingborough. According to the Act obtained by the promoters, the line would, instead of following the road, be taken across some low-lying fields in the Nene Valley between the two towns, but these meadows are so often flooded that the cost of this route, in consequence of the number of arches required, would cost over £20,000. Hence the promoters have decided that unless they can take the line along the road they will be compelled to drop the scheme altogether. The difficulty is that if the line is taken this way the Nene bridge at Higham Ferrers Station must be widened. The question then comes in as to who should widen the bridge, and is at present the subject of controversy.

Aberdeen.—An open-air meeting has been held to discuss the question of running cars in the city on Sundays. The following resolution was adopted: "That this meeting of citizens beg to urge upon the Aberdeen Town Council the necessity for the institution of a service of Sunday cars which can be fully taken advantage of by all members of the community who desire to do so; also, that this meeting call upon the Council to provide a service of early cars for workmen, and to adopt at the same time a proportionate scale of ½d. fares over the entire system." The Town Council have resolved to join other corporations in a representation to the Board of Trade in connection with certain new regulations proposed to be made by that department in regard to speed indicators, the erection of guard wires over trolley lines, and other matters. On Monday the Town Council decided, by 20 votes to 12, to run the cars on Sundays.

Central London Railway.—The company have just closed a contract with the British Thomson-Houston Company covering 64 motorcar equipments and 160 trail-car equipments. The equipment for each motorcar is to consist of two B.T.-H. 125-h.p. traction motors, one motor truck of the swinging bolster type with 33in. wheels, one motor-driven air compressor with a capacity of 35 cubic feet of free air per minute, one automatic governor, arranged to cut in the compressor at 80lb. air pressure in the main reservoir and to cut it out at 90lb. pressure, and one complete B.T.-H. master train-control equipment for the motors. Each trail-car equipment consists of the necessary control circuit cable and wiring material for the controller train line required for this system. Each train will consist of two motorcars and five trailer cars, the motorcars being at each end. We understand that the trains are now equipped with small chemical fire extinguishers.

Hull.—The members of the Corporation Tramways Sub-Committee on Friday conducted some trials of three life-saving guards for the tramcars. A "dummy" boy, weighing 2½ stones, and a "dummy" man, weighing nine stones, were utilised for the test, and there were three guards. The first subjected to practical examination was one recently patented by Mr. Robinson Burn, a local man. In this case, immediately the object came against a shutter in the front of the car the shutter went up, and down came a net faced with a roller, which rolled the bodies into the net. The next test was with the Tidswell guard. In this case the results are said not to have been so satisfactory as with the Burn's patent, because the bodies were pushed along some distance instead of being immediately taken up, as in the first case. The third guard tested did not give satisfactory results, and the sub-committee subsequently met and passed a resolution in favour of Mr. Burn's guard. The guard will accordingly be fitted to one of the cars and subjected to Board of Trade inspection.

Whitefield.—The proposed tramway agreement with Salford has been carefully considered in committee, and the clerk was instructed to further revise the same so as to provide that the Council should have a voice in the fixing of the fares and a minimum car service; that a service of through cars should be provided to the Council's satisfaction; that the Corporation should apply for powers to run the cars down the Bury New-road through Strangeways to Manchester, and failing obtaining the same should grant the Manchester Corporation running powers over their lines between the Grove Inn and Prestwich; that running powers should only be granted by Salford to any other corporation or company upon terms to be approved by the Council, or, failing agreement, to be settled by the Board of Trade; and, in addition to other matters, that all arrangements between the Salford Corporation and any other authority or company relative to the user of the tramway shall be subject to the approval of the Council, with the right to refer to the Board of Trade in case of difference.

The District Railway.—The British Thomson-Houston Company, Limited, have recently closed a contract with the Metropolitan and District Railway for the switchboard to control the 10 5,000-kw. 11,000-volt generators and other electrical auxiliaries in their generating station. We understand that it will consist of 47 black enamelled slate panels, divided as follows: four generator exciter panels, one exciter feeder panel, two rotary converter panels, one direct-current generator panel, one storage battery panel, two direct-current feeder panels, one low-tension transformer panel, three induction motor panels, 12 feeder panels, 10 generator instrument panels, and 10 generator controlling panels. All generator and feeder circuits are to be controlled by B.T.H. high-tension oil switches, type H, mounted in fireproof brick compartments, which are capable of opening a dead short-circuit of the entire station, and which are to act as automatic circuit breakers in the feeder circuit, being capable of adjustment within wide limits. They will also be capable of opening the circuit in case of reversal of current, thus forming an automatic circuit breaker without the interposition of high-tension fuses.

Walsall.—Particulars to hand state that the total length of lines open for traffic at present is 6 miles 17 40 chains. The undertaking was originally the property of the South Staffordshire Tramways Company, but was purchased by the Corporation in 1901. The tramways are worked on the overhead trolley system. The Corporation have leased the lines for three years to the South Staffordshire Tramways (Lessee) Company, Limited, and the term will expire on Dec. 31, 1903. The Corporation then intend to work the lines themselves, in conjunction with certain extensions. These are provided for under the Walsall Corporation Act, 1900, whereby the Corporation are authorised to construct 15 miles 5·90 chains of tramways. Contracts are now being signed for the construction of about 7¾ miles. The borough electrical engineer (Mr. Alexr. Wyllie) has superintended the arrangements for the electrical equipment on the overhead system of the lines, and the borough surveyor (Mr. R. H. Middleton) has got out the plans and specification for the track. The contracts have been let as under: permanent way, Messrs. Wm. Griffiths and Co., of London; electrical equipment (overhead), Messrs. Robert Blackwell and Co., Limited; cables, Callender's Cable and Construction Company, Limited, of London.

Bingley.—The District Council have agreed to terms with a syndicate with regard to tramways through Bingley. The proposed line would run from Shipley to Keighley. The agreement provides that the company shall construct the tramway and put up the equipment from the Shipley boundary to the extent of the Bingley district, a total length of 3¼ miles. The company will take current from the Council for running the tramways at a price in excess of the cost of the Council. The District Council shall apply for a provisional order next October for powers to construct tramways, and the cost of the provisional order will be paid by the company, the order when obtained to be transferred to the company, who will be granted a lease to work the tramways for a period of 21 years, the term to be extended by subsequent powers to 30 years. The company will also pay to the Council £500 a year for 30 years, this sum to include £100 per mile for the maintenance of the track, interest at ½ per cent. on £27,000, and £40 for contingencies. In addition, the company will contribute £2,000 towards the cost of making the new road past the parish church, for which the Council will have to obtain parliamentary powers. At the end of the lease the whole of the plant, with the exception of the cars and the car-sheds, will become the property of the Council.

Kensington.—The Law Committee reported at the last meeting of the Borough Council that as a result of negotiations they had come to a provisional agreement with the promoters of the Central London Railway Bill, embodying not only the usual protective clauses, but also what they deemed to be satisfactory terms for the surrender of a portion of the Wood-lane depôt to the company. The same committee reported that they had received a communication from the Council's solicitors, stating that they had been in negotiation with the promoters of the Metropolitan District Railway Bill with regard to the proposed route for the conduits and mains for the electrification of the company's railway, and had provisionally agreed a special clause for insertion in the Bill, providing that plans and sections of all works proposed to be constructed, showing the streets along which the proposed conduits and mains were to be laid, should be approved by the Board of Trade. The proposed clause also provided that no enlargement or alteration of the works should be made without the similar approval of the Board of Trade, who before giving such approval should have regard to the safety and convenience of the public, and should consider any representations made to them by the local authorities. They had instructed the Council's solicitors to withdraw the opposition to the preamble of the Bill, provided that the special clause above referred to was inserted, together with other clauses to be agreed for the protection of the Council.

Sunderland.—The annual report of the Tramways Committee during the financial year just expired states that the success of the system has been very marked. The traffic receipts, the number of passengers carried, and the mileage run show a large increase. The figures compared as follows: 1901—receipts, £22,256; passengers carried, 5,035,935; mileage run, 397,562. Last year the figures were respectively £56,243, 13,596,808, and 1,170,202. Since the inauguration of electrical traction in Sunderland there have been no accidents causing loss of life, broken limbs, or grave damage to persons or properties. The patent guards have been found to work very satisfactory in practice. On one occasion, in High-street, a girl stepped in front of a car, was knocked down, the lifeguard saved her, and she was picked up with practically no injnry. Experiments have been made with patent dry seats, but the entirely satisfactory outside dry seat has yet to be found. Some time ago it was resolved to fit up a car with the "Never-wet seat" for the purposes of experiment, and as this was considered to be the best seat tried, the 10 double-deck cars on order will be fitted with it. Everything possible has been done to maintain the various properties of the committee in a high-class condition. The overhead line was inspected weekly, and any weak places that were discovered were immediately put right. The financial condition of the undertaking is represented as follows: The traffic and other receipts for the year ending March 31, 1902, were £57,307. 16s. 3d. The expenditure was—working expenses, £30,719. 2s. 11d.; interest and depreciation, £18,846. 6s. 2d., leaving a net profit of £7,742. 7s. 2d. The car miles run were 1,170,207; units of electricity consumed, 1,232,910; passengers carried per car mile, 11·6; income per car mile, 11·75d.; expenses per car mile, 10·16d.; net profit per car mile, 1·59d. The percentage of gross profits on capital expended was 11·89d., and net profits on capital 3·46d. The average receipts per day for the year were £154. 0s. 8½d. The capital account shows an expenditure of £233,540, while the net revenue account shows that £500 have been transferred to the compensation fund, £12,159. 3s. to the depreciation fund, and £7,000 carried forward in aid of the borough rate.

LIGHTING AND GENERAL.

Octacamund (India).—A large electric lighting scheme is in preparation.

Paisley.—The salary of Mr. Parkinson, the electrical engineer, has been increased by £50.

Norwich.—The Corporation Electricity Bill has been read a second time in the House of Lords.

Stalybridge.—Arrangements are being made for the purchase of a site for a generating station.

Long-Distance Telephones.—Berlin, Berne, and Rome will be connected by telephone in August.

Strathpeffer.—We understand that an electric lighting scheme is shortly to be introduced at Strathpeffer.

Newport (Mon.).—It is intended to place electric arc lights in the bell tower of the town hall on Coronation Day.

Coatbridge.—The Scottish House-to-House Electricity Company, Limited, are about to lay further mains in the burgh.

City of London.—A report asking for authority to spend £700 in lighting the City School by electricity has been adopted.

Change of Address.—The Mica Boiler-Covering Company, Limited, have removed to Cornwall-buildings, 35, Queen Victoria-street.

Ware.—Mr. H. Wall Wilkinson has been instructed by the Urban District Council of Ware to prepare a report on electric lighting.

Battersea.—The Borough Council have obtained sanction to a loan of £456 for lighting the baths, Latchmere-road, with electricity.

Aylesbury.—The Urban District Council have applied to the Board of Trade for an extension of their electric lighting provisional order.

Digitized by Google

Bootle.—The lighting of the whole borough will soon come before the Council. On the whole they appear to be in favour of electric lighting.

Thomas Parker, Limited.—The directors have resolved, subject to final audit, to declare a dividend of 10 per cent. for the year ending April 30, 1902, and to carry the balance forward.

Whitehaven.—From the applications for current for power received by the Town Council, it appears that there is every prospect of a considerable amount of custom during the daytime. .

Concert.—The Electrical Trades Union held a grand Bohemian concert at the Finsbury Town Hall, Rosebery-avenue, W.C., during which a new banner was unveiled by the Mayor of Poplar.

South Wales Electrical Power Distribution Bill.—This Bill, which has already passed a committee of the House of Commons, has been ordered to be reported for third reading in the House of Lords.

Paris Embassy.—At the fête on Saturday night at the British Embassy in Paris the gardens were exquisitely illuminated by 3,000 electric lamps enclosed in translucent celluloid flowers of every variety and colour.

Fareham.—The Portsmouth Corporation are including Fareham in their telephone area, and have asked the necessary permission to erect poles. The Urban District Council will take no action until detailed plans arrive.

Cleckheaton.—The District Council intend to apply for sanction to borrow a further £6,000 for electricity purposes. The charges for electricity for lighting and motive purposes have been fixed at 5d. and 2d. per unit respectively.

Heywood.—The Electric Lighting Committee have decided to supply current where the mains are now laid at 3d. per unit for illumination purposes at the Coronation, consumers to provide their own fittings and devices.

Aberystwyth.—The Postmaster-General last Friday received a deputation appointed by the conference held at Aberystwyth on May 29 to consider the extension of the telephone through Montgomeryshire to that town.

Wireless Telegraphy.—Communication by wireless telegraphy has been established between Rome and the island of Caprera, off Sardinia, 250 miles distant. The system is that perfected by Captain Bononio, of the Italian navy.

Bournemouth and Poole Electricity Supply Co.—The transfer books and register of holders of debenture stock of this Company will remain closed until the 30th inst., inclusive, preparatory to the payment of the interest due on July 1, 1902.

Manchester.—The Electricity Committee have decided to supply electric current at ordinary rates of charge to consumers who desire to temporarily increase the number of their lamps. etc., for outside illuminating purposes during the Coronation week.

Taunton.—The Town Council have decided to apply to the Board of Trade to sanction the alteration of the financial year so as to make it in future terminate on March. 31, and be in accordance with the financial year of the Corporation's general accounts.

Colne.—The Electrical Committee have decided to adopt an alternative system of charging for current for lighting purposes, and in future consumers will have the option of adopting the maximum demand system or the flat rate of 4½d. per unit system.

Bexhill.—Messrs. Preece and Cardew have resigned their positions as the Council's consulting engineers. We understand that Mr. Robert Hammond has been appointed to report upon the present position and future requirements of the electric light works.

County of London and Brush Provincial Electric Lighting Co.—The transfer books and register of holders of debenture stock of this Company will remain closed until the 30th inst., inclusive, preparatory to the payment of the interest due on July 1, 1902.

Electric Lighting and Traction Company of Australia, Limited.—The transfer books of the £75,000 5 per cent. debenture stock will remain closed from the 17th to the 30th inst inclusive for the preparation of interest warrants for the half-year ending June 30, 1902.

Limerick.—The Borough Council have obtained an opinion of Mr. Browne, K.C., according to which the Corporation are in a position to delegate their powers and duties under the Limerick electric lighting order to the Gas Committee, provided the leave of the Board of Trade is obtained.

Bangor.—The borough accountant has negotiated a loan of £5,480 for refuse destructor purposes. The electrical engineer (Mr. Price White) in his last report states that at the end of the month of April there was an increase of 58 per cent. in the number of units of electricity sold.

Thirsk.—The Parish Council have adopted the following resolution: "That in the event of the Northern Counties Electrical Company erecting works at Thirsk or Sowerby, this Council will adopt electricity for lighting the street lamps at a price not exceeding the price paid for gas for one year."

Halifax.—On Coronation Day an electric searchlight is to be erected on Beacon Hill. It will be of the Admiralty type, and extremely powerful, taking a current of 100 amperes at a pressure of between 70 and 80 volts. The current will be taken from the tramway wires on Southowram route.

Jandus Arc Lamp.—In addition to the Davy Construction Company, who, as already announced, have recognised the Jandus master patents, we understand that the Reason Manufacturing Company have recently signed an agreement by which they also have become licensees of the Jandus Company.

Portsmouth.—An estimate is being prepared for providing communication between the floors of the town hall by means of a passenger lift. It is stated that the cost of the lift installed at the Pearl-buildings is only ½d. a journey, and the tramway direct current can be used to work the lift should its erection be decided upon.

Truro.—A proposal that Messrs. Crompton and Co., Limited, should be permitted to put up and work an electric light installation in the city at their own cost and risk, giving, if desired, the Corporation the option of purchase at stated periods, has been referred to the special committee, of which Mr. Trevail is the chairman.

Dumfries.—The Town Council have rescinded a former resolution binding them to carry through the proposed installation themselves. Before proceeding further they await the report by Prof. Capper, and several members have indicated a strong desire to have a direct reference to the ratepayers before any further important step is taken.

Gravesend.—We understand that to-day an agreement between Messrs. Multon and Wallis and the Corporation for the completion of the building of the generating station will be submitted. The Town Hall and Market Committee recommend that the town hall and its buildings and offices and the market be lighted with electricity.

Coronation Illuminations.—The Electrical Company, Limited, have been entrusted with the order for the illumination of the Canadian arch in Whitehall, London. More than 5,000 incandescent lamps will be used for this purpose. This is probably the most important electrical illumination for the Coronation festivities in the whole of the United Kingdom.

South African Appointment.—The Kimberley Borough Council have selected, from 14 applications for the appointment of electrical engineer, Mr. J. Mordy Lambe, of Rondebosch, chief assistant electrical engineer to the Cape Peninsula Lighting Company, Limited. Mr. Lambe was formerly with Messrs. C. A. Parsons and Co., Heaton Works, Newcastle-on-Tyne.

Lytham.—The Urban District Council have resolved to apply to the Board of Trade for an extension of time for the completion of the works under the electric lighting order. Mr. T. Parker, to whom the tenders have been referred, has informed Messrs. Dick, Kerr, and Co. of this resolution, stating that the Council are not at present in a position to enter into a contract.

Aberdeen.—The Town Council on the 16th inst. adopted a report of the Watching and Lighting Committee recommending that the Council do not adopt the Kitson lamps, erected experimentally in Union-street, it being deemed inadvisable to take over the lamps, seeing that they had an electric station, and that Union-street was lit with electric light from Castle-street to Bridge-street.

Wandsworth.—At the last meeting of the Borough Council the receipt of a letter from the London County Council emphasising the necessity of establishing testing stations for the supply of electricity in the borough was reported, and the town clerk was instructed to forward to the London County Council a list of premises where periodical tests of the pressure of electricity can be made.

Blast by Electricity.—At a new freestone quarry opened up lately by Messrs. A. and J. Frame at Patterton, near Thornliebank, a special blast was recently conducted by Messrs. Fleming and Co., 31, Robertson-street, Glasgow. Five holes, about 36ft. deep, were drilled and charged with special gunpowder and fired simultaneously by electricity, the result being most gratifying to all concerned.

W. T. Henley's Telegraph Works Co.—We are informed that certain differences have arisen between this Company and Messrs. Callender's Cable and Construction Company, Limited, as to the terms of the proposed amalgamation, which in the view of both Boards render it impracticable at any rate for the present, and the negotiations have therefore, by mutual consent, been treated as at an end.

Colwyn Bay.—Mr. Tudman in his last report states that the units generated at the electric light works last month were 5,518; maximum load, 135·1 kw.; current consumed by street arcs, 307; promenade arcs, 770; number of consumers connected up to date, 90. A recommendation to supply the whole of Greenfield-road and Lawson-road, at an estimated cost of £274. 2s., is before the Electric Light Committee.

Burton.—With respect to the profit of £545. 6s. 8d. for the past year in the electric light department, the sum of £520 is to be repaid to the gasworks department on account of the £1,020 advanced by the latter department, and the balance of £25. 6s. 8d. carried to a new account to be called a renewal fund. The quantity of electric light sold during the past month was 11,006 units, showing an increase of 3,811 units.

Bermondsey.—The Council have approved of the proposal of the London Electric Supply Corporation to lay mains of high and low tension along Tooley-street, Tower Bridge-approach, Horselydown-lane, Gainsford-street, and Queen Elizabeth-street. The County of London and Brush Provincial Electric Lighting Company have obtained permission to construct a transformer box in Lambeth-road under their Southwark order.

Huddersfield.—The committee recently appointed to consider a proposal to establish in Huddersfield works for the manufacture of electrical machinery and appliances have had several meetings, and we understand that the negotiations with Messrs. Kolben, of Prague, are not progressing favourably. Messrs. Witting have opened negotiations for the amalgamation of their business in London with the proposed Huddersfield business.

Brierfield.—The charges for electricity are to be on a sliding scale, the maximum charge being 4½d. per unit, and a discount of 5 per cent. will be allowed to consumers if account be paid within 14 days from day of demand. This means that if a consumer uses 3,000 units per year the cost will go down to 4½d. per unit, 5,000 4d. per unit, 8,000 3¾d. per unit, 10,000 3½d. per unit. If over 10,000 units are used the charge will drop to 3¼d. per unit.

Digitized by Google

Hammersmith.—The estimates of the electricity department for the year ending March 31, 1903, show an expected income of £26,197, and a prospective net profit of £1,507. Since the previous Council meeting 20 additional consumers have been connected, representing a maximum of 862 8-c.p. lamps, the present number of consumers now taking current from the mains being 1,042. A main is to be laid in Blythe-road at a total estimated cost of £95s. 4s. 1d.

Feltham.—At the last Parish Council meeting it was stated that the clerk had placed himself in communication with the General Post Office authorities with reference to the establishment of a telephone call office at Feltham, who had replied that Feltham was in the Windsor call area, and that it was thought the business likely to be done there would not justify the extension asked for. It was decided to further communicate with the authorities on the subject.

City and Guilds of London Institute.—Entrance examinations will be held in September for the courses of instruction at the institute's Central Technical College, Exhibition-road, which are for day students not under 16 years of age; and at the City and Guilds Technical College, Finsbury (Leonard-street, City-road, E.C.), for day students not under 14, preparing to enter engineering and chemical industries, and for evening students. Full particulars appear in another column.

Twickenham.—The District Council have decided, in accordance with the terms of the existing agreement with the National Telephone Company, three months' notice be given them of the Council's intention to terminate the same, that an agreement be entered into with the Post Office authorities for a private wire at a charge of £8. 10s. per annum, with charge for additional calls. Statutory notice of intention to lay electric light mains in Cresswell-road, Morley-road, and Alexandra-road has been received.

General Electric Company's Fire.—We are informed that the directors of the General Electric Company (1900), Limited, owing to the large stocks held at their branches, and the exceptional facilities for manufacture at their various works, are enabled to efficiently cope with the strain which the recent fire has put upon their resources, and all orders can be executed with promptitude. We are asked to state that as some order sheets may have been lost, customers noticing a delay should forward copies to ensure prompt dispatch.

Cardiff.—The borough electrical engineer (Mr. Arthur Ellis), in his report for the month of May, 1902, shows, as compared with May, 1901, an increase of 33 per cent. on lamps connected and an increase of 33 per cent. in units generated. The estimated revenue for the month was £909. 18s. 4d., as against £696 for the corresponding month—an increase of 30 per cent. The public and private supply had been fully maintained, and no complaints had been received. Experiments are being made with arc lamps placed on tramway poles.

Hebburn.—The Northern Counties Electricity Supply Company having submitted a plan showing the various streets comprising the whole of Hebburn Quay and Hebburn New Town in which they purposed laying down cables for electric lighting, it was found that the number of streets specified exceeded the number set out in the compulsory area. The Post Office authorities are to be served with notice of the electricity company's intention to lay the cables. We understand that the District Council have rejected the plans of the company for a power station.

Oban.—The rate for current for lighting has been fixed at 6d. per unit, and for power 3d. per unit. The charge for meter rents will be as follows: for 10-ampere meter, 2s. 9d. per quarter; 25 amperes, 3s.; 50 amperes, 3s. 6d.; 100 amperes, 4s.; 150 amperes, 5s. 6d.; 200 amperes, 7s. 6d. Provided 38 8-c.p. lamps are guaranteed for premises along the route, an armoured cable is to be laid in Soroba-road from the high school to near the railway bridge, and the public lamps in that section of Soroba-road are to be lighted by electricity. Mr. S. Williams, Corporation electricity works, Ayr, has been nominated as assistant engineer.

Stock Exchange.—Applications have been made to the committee to appoint a special settling day in the Bournemouth and Poole Electricity Supply Company's 7,500 6 per cent. cumulative second preference shares of £10 each (issued at £1 per share premium), £4 paid, of which £3 is capital and £1 premium; and to allow the following securities to be quoted in the official list: British Insulated Wire Company's further issue of 10,000 6 per cent. cumulative preference shares of £5 each, fully paid, Nos. 70,001 to 80,000; and the County of London and Brush Provincial Electric Lighting Company's further issue of 10,000 6 per cent. cumulative preference shares of £10 each.

July "Smart Set."—The *Smart Set* for July opens with a novelette by Edward S. Van Zile, entitled "Clarissa's Troublesome Baby," a clever and amusing story reminding us—we forget the title for the moment—of the delightful yarn about the old man who grew 10 years younger week by week until he dwindled into a tiny baby. The short stories have all a good special point in one direction or another, so that selection would be invidious. Mr. Gilbert Parker, M.P., contributes a timely article, "The Crowning of the King," in which he discusses the significance of the Coronation of Edward VII.; and the Duchess of Somerset contributes an interesting essay, entitled "Relating to Toasts Past and Present." Much that we have said of previous numbers holds good of the present one, which contains 50 signed contributions, besides numberless bits of humour in prose and verse scattered throughout the number.

Islington.—At to-night's meeting a report from the Lighting Committee will be submitted stating that from the accounts of the electricity undertaking for the year ending March 31, 1902, it will be seen that during the year there has been a further capital outlay of £43,508. 4s. 7d., and that the total capital invested now stands at £365,842. 12s. 10d. The total expenditure on revenue account amounted to £24,639. 17s. 8d., and the income for the year to £41,308. 8s. 3d., leaving a gross profit of £16,668. 10s. 7d. It is satisfactory to note that after payment of interest and redemption of debt there remains a net profit on the year's working of £1,402. 6s. 6d. The accounts are supplemented by the report of the electrical engineer and by some figures, which will be found of considerable interest. It is proposed to lay a low-tension distributing main, at a cost of £51, in Holloway-road.

New Issue.—An issue is being made of 49,500 £1 shares in the Peking and North China Electrical Corporation, which has a capital of £100,000. The objects of the company are to carry on the business of generators and distributors of electric energy in China, and to take over the concessions, etc., of the Siemens und Halske Aktien-Gesellschaft, Messrs. H. Mendl and Co., and the Chinesische Elektricitäts-Gesellschaft, M.B.H., who have acquired from the Imperial Chinese Government the right to establish an electric lighting station at Peking. The prospectus states that prior to the Boxer rising an electrical plant was established at Peking, and installations had been made in the Legation quarter, but a few days after the station had commenced supplying current the Boxers destroyed the buildings and books. This company will acquire the land on which that station stood, value at £2,000, and the plant, machinery, and stock at present in Peking, and Crompton and Co. have undertaken to establish the electrical plant and act as managers to the company in the Chinese capital.

Newton Abbot.—The Urban Electric Supply Company are erecting works in Teign-road, Messrs. Parker Bros. having secured the contract. The building is of brick, with red cornices, and will contain four large offices, engine-room, boiler-room, battery-room, showrooms, stores, and workshops. A temporary chimney will be constructed of steel plates for use until the brick stack is erected. Babcock-Wilcox boilers are now at the station awaiting delivery, and they will be put in forthwith. The high-speed engine, 100 h.p., and running at about 450 revolutions a minute, is by Messrs. Belliss and Morcom, Birmingham. The supply will be on the three-wire system, and batteries are to be installed to ensure a continuous and steady supply. The company will commence to lay the mains about the end of July, and hope to be ready with the light by next winter. Each of the mains consists of three conductors of copper, insulated with vulcanised bitumen supported on bridges in a wood trough, which is then run in solid with refined Trinidad bitumen, and the whole covered by a continuous layer of hard tiles. The boxes to be put in at the feeder point where the feeder joins the distributor will be of the pillar type set in the footway on the kerbstone. Those at other points where the distributors join one another are cast-iron boxes, with covers sealed by an oil lute and set in brick pits in the footway with separate street covers filled in with concrete. Electric energy is to be supplied by these mains by direct current of low potential on the three-wire system, the pressure at the consumers' terminals being 240 volts, and the pressure in the outers of the cables 460 volts to 530 volts, according to the load. Mr. F. C. Pay, A.I.E.E., is the resident engineer.

Harrogate.—The Corporation have received an elaborate report upon the proposed reduction in charges. In his introduction the chief engineer (Mr. Geo. Wilkinson) says: "The net profit of the electricity supply business for the past year exceeds £1,600. In view of this fact you may wish to make some modification in the rates. The business is at present prosperous enough to allow of some concessions being made to consumers, but in considering same it is as well to bear in mind that during the coming year interest and sinking fund has to be paid on an increased capital expended upon plant and machinery, which is not at present profitably employed, also the undertaking will be called upon to pay an income tax of about £400 during the year. The rates we have at present in force are as follows: Lighting and general—(1) uniform 6d. rate; (2) 6d. rate for the first hour, as shown by the maximum demand indicator, and 4d. afterwards; (3) 6d. and 2d. for consumptions equal to 15,000 units per annum, and over. Power: (1) same as Nos. 1 and 2 for lighting; (2) 2d. per unit where the use averages about five hours per day at two-thirds load. Electric radiators: (1) a flat rate of 2d. per unit; (2) 1½d. per unit where the use does not average less than three hours per day during any quarter. Cooking: 6d. per unit for the first hour and 2d. afterwards. Public lighting: (1) 2½d. per unit." As to the suggested reduction of tariff for private consumers Mr. Wilkinson says: "The present rate is 6d. per unit for the first hour, based on the reading of the maximum demand indicator, and 4d. afterwards, and suggests that the 4d. rate should be reduced to 3d. after the second hour. The effect of this reduction will be to give long-hour consumers, which are our most profitable customers, their supply at a lower average charge per unit. It is also expected that this reduction would encourage consumers to put lamps into dark places where they would be burning continuously, and it would discourage the unprofitable practice of putting lamps into shop windows only and not lighting the back premises. To enable you to decide if it is desirable to make any reduction in the general rate for electricity supply for Corporation purposes, I give the following figures: At present street-lighting is paid for at the rate of 2½d. per unit, and the following figures give the amount paid for the year at this price, and the amount which would have been paid if a 2d. rate had been in force—at 2½d. per unit, £983. 15s. 2d.; at 2d. per unit, £787. 0s. 2d.; difference, £196. 15s. For ordinary office and public building lighting, electric baths, etc., the charges have been 6d. and 4d., and the Corporation have paid at these rates the following for the year ending Dec. 31, 1901: 26,354½ units at 6d., £658. 17s. 3d.; 16,155 units at 4d., £269. 5d.—total, £928. 2s. 3d. And to reduce the Corporation rates to 6d. and 2d. would have modified the Corporation accounts accordingly as shown: 26,354½ units at 6d., £658. 17s. 3d.; 16,155 units at 2d., £134. 12s. 6d.—total, £793. 9s. 9d.; saving £134. 12s. 6d. Alterations are being made at present in the Royal Baths so that all the electricity used for the electric baths may be obtained at a flat rate of 2d. per unit. All the figures given in this report disregard the 5 per cent. allowed for prompt payments."

Digitized by Google

Ashton.—The Hurst Urban District Council have consented to the laying a cable to the district infirmary through that portion of the Council's district situate at the junction of Mossley-road and Fountain-street. Tenders are to be obtained for the necessary cable in Katherine-street for an arc light at Albion Schools. A sub-committee has been formed to confer with the Electricity Committee and arrange the price of current for street-lighting during the present financial year.

A New Thames Canal.—The Canal Bill which has been promoted by cement manufacturers and others whose works abut on the Medway has passed the House of Lords, and is now before a Select Committee of the House of Commons. Power is sought for the construction of a canal from Rochester to a point on the River Thames about two miles below Gravesend, about five miles in from the start. It is intended that the haulage on the canal should be done by electrical power.

Bristol.—At every meeting of the Electrical Committee applications for extensions of the mains come up for consideration, and extensions were conceded last week for Silverthorne-lane, Wells-road, Portwall-lane, Hebron-place, Bedminster, Bath-street, Limerick-road, Prince-street, and on Clifton-down. The committee declined to make extensions in Wildway-street (St. Philips), Coronation-road, North-street (Bedminster), and Westbury-park; while reconsideration is to be given to applications from Hope Chapel (Clifton) and Chandos-road.

Bridgend.—An enquiry was held on Wednesday into an application of the Council to borrow £4,000 for electric lighting purposes. The Council have decided to charge consumers 6d. per unit at first, but they expect to be able to reduce this charge in a year or so. At this rate the Council will be in a position to put in connections free of cost. Mr. Hill, of the South Wales Electrical Power Company, and a representative of the Council are making a canvass of the town to ascertain how many private houses and business establishments will use the electric light.

Teddington.—The Electric Lighting Committee reported at the last meeting the receipt of a letter from Messrs. Edmundson's Electricity Corporation, Limited, stating that their electric light mains were laid up to the boundary of the Council's district, and they would be prepared to furnish a supply to Teddington and enter into negotiations for this purpose. The Council decided to invite tenders from companies stating the terms upon which they would be willing to take over the provisional order granted by the Board of Trade under the Electric Lighting Acts, 1882 and 1888, to the Council.

Slough.—The Council in committee having duly considered the advisability of transferring the Slough electric lighting order to the Windsor Electrical Installation Company, or to some other company to be formed for the purpose of acquiring the order, last week resolved that the order for lighting Slough and Datchet by electricity be so transferred upon the terms set forth in the draft deed of transfer as settled by Mr. G. H. Charsley and the solicitor to the Windsor Company and upon condition that any new works will be erected within the urban district of Slough, and that the clerk be instructed to take the necessary proceedings to enable such transfer to be carrried out.

Walsall.—The last report of the Electric Lighting Committee shows that the total number of consumers supplied on May 31 last was 227. During the past month the total units generated at the station were 33,039. The total output from the main generators was 31,660 units. The total units from the transformers was 24,088 (estimated). The units registered on the meters amount to 21,640. The machinery was run for 484 hours. The wages paid amount to £90. The Town Council have decided to apply for sanction to borrow £1,325 for the installation of heat economisers and fan, with the requisite engine power, at the Wolverhampton-street generating station, including the brickwork and fittings.

Dewsbury.—In connection with the report of the electricity department for year ending March 31, 1902, we note that this is the first full year in which the reduced rate of charges has operated—*i.e.*, 6d. for the first hour instead of 1½ hours, as before, and this has made a difference of £270 in the year's revenue to the advantage of their consumers. There were used during the year 1,300 tons of fuel (rough slack)—151 tons at 12s., 68 at 11s., 22 at 10s. 6d., 140 at 10s., and 920 tons at 9s. 6d. per ton. The number of units sold is 258,576. Of their total units for lighting 49 per cent. is at 6d. per unit and 51 per cent. at 3½d., as against 60 and 40 per cent. respectively under the old scale of 1½ hours maximum. The committee have also supplied free 4,500 units to the public library.

Kingswinford.—At the last meeting of the Rural District Council, the clerk read correspondence from the solicitors to the Midland Electric Corporation for Power Distribution in respect to the delay in the provision for electrically lighting the district and the application of the Council to the Board of Trade to arbitrate. They stated that the company had met with difficulties and delays in completing the generating station at Ocker Hill, but this was now being completed, and they believed that the engines were being run this week. The work of laying the remaining cables would not take long, and there was no reason for the Council applying to the Board of Trade. The work would be done at an early date. It was decided to instruct the clerk to write the company that they must complete the whole of he work.

Tunbridge Wells.—It is the intention of the Electric Lighting Committee to charge half price, or 3d. per unit, for all current used in illumination during Coronation week. At the last meeting of the Lighting Committee the borough surveyor submitted a report upon chimney shafts erected and now in course of erection by the Alphons Chimney Construction Company. The matter was referred to the electrical engineer and borough surveyor to prepare a specification. The electrical engineer reported on the question of having the maximum demand indicators calibrated so as to enable consumers to obtain a rebate in respect of each quarter instead of half-yearly, and stating that the manufacturers would supply cards and recalibrate the instruments at their own expense. The consideration of the matter was deferred.

Woolwich.—The Borough Council intend to apply for a loan of £101,000 for the purchase of the Woolwich District Electric Lighting Company's undertaking. At the last meeting of the Council the Town Clerk reported that on May 23 he had completed the purchase by the Council of the Eltham portion of the Blackheath and Greenwich District Electric Light Company's undertaking, and had since notified all the Eltham consumers, numbering 19, that the Council are now the owners of the undertaking, and that all accounts due from them for current supplied during the present quarter should be paid to the Council. A circular has been addressed to the residents of Eltham, together with a pamphlet prepared by the electrical engineer, giving particulars of supply.

Stoke Newington.—The last report of the Electric Lighting and Sites Committee states (1) that the laying of the mains in the High-street and Stoke Newington is now completed; (2) that the Board of Trade have made the Stoke Newington electric lighting order, which empowers the Council to supply electricity within so much of the borough as is not within the area of supply to which the Hackney Electric Lighting Order, 1893, extends, and that the same has been included in a Confirmation Bill now before Parliament; and (3) that the Local Government Board have made an order, subject to confirmation by Parliament, for enabling the Council to put in force the compulsory clauses of the Lands Clauses Act with reference to the lands required by them for the purpose of providing a site for the erection of a refuse destructor.

Australian Contracts.—Messrs. Noyes Bros., of Sydney, N.S.W., the Australian representatives of the British Westinghouse Electric and Manufacturing Company, Limited, have recently secured two important electric power contracts. One is for a complete conversion of the horse tramway system of Adelaide, South Australia, to electric traction. In all, there are some 65 miles of track to be dealt with. The other contract is for a complete electric power installation to be put down in the new railway works of the Queensland Government railways. These works are at Ipswich, near Brisbane, and the plant put down will consist of 800 h.p. of generating plant, with numerous motors for machine driving. The system is to be of the two-phase type. The whole plant, steam, electric, and auxiliary apparatus, is covered by the one contract, the price of which amounts to over a quarter of a million pounds.

Stafford.—The Electric Lighting Committee's report, adopted at the last meeting of the Town Council, referred to Mr. J. Clothier's resignation as electrical engineer, and stated that during the time Mr. Clothier had been in charge of the electric lighting works large extensions of plant had taken place, the streets had all been recabled, and the doubling pressure of supply had been carried out under his supervision. He had performed his duties to the entire satisfaction of the committee, and his resignation was accepted with regret. A honorarium of £50 has been granted him. Steps are to be taken for applying to the Board of Trade for a provisional order to supply electricity outside the borough. The following amended scale of discounts will be allowed on accounts for current consumed per quarter—namely: up to 140 units, 2½ per cent.; between 140 and 700 units, 5 per cent.; between 700 and 1,400 units, 7½ per cent.; above 1,400, 10 per cent.

Coventry.—With regard to the enquiry noted in our last issue, we find that the sum of £22,483 to be borrowed includes £725 as the excess cost of the purchase of a 600-kw. alternator instead of a 400-kw. one previously sanctioned, and £6,725 for a new 600-kw. steam alternator, £640 for large boilers and forced draught, £850 for steam-pipes, £800 for injection and discharge pipes to new hot-well, £50 for second hot-well, £200 for grease filter, £60 for second grease filter, £125 for second evaporator and erection, £350 for switchboard extensions, £100 for larger foundations for alternator, £250 for foundations for new plant, £1,850 for coal bunkers and conveying plant, £2,250 for meters and house connections for 130 consumers, £5,000 for mains, £500 for transformers, and £2,000 for purchase of motors. The Electric Light Committee have been empowered to dispose of the No. 1 plant at the electric light works, which has become too small and useless, and its place is to be taken by more up-to-date plant.

Arc Works Sports.—The Arc Works Club, which is an athletic club composed entirely of the employés of Messrs. Crompton and Co., Chelmsford, held their annual meeting at the club ground, Chelmsford, on Saturday last. For the comfort and convenience of those travelling from London saloon carriages were attached to the 10.55 train from Liverpool-street. Upon arrival at Chelmsford conveyances were in attendance, and the party driven to the Arc Works, where by Colonel Crompton the visitors were conducted through the various manufacturing departments, the Mayor of Chelmsford, J.P., V.D., and Major Rasch, M.P., honouring the company by their presence. After luncheon another drive brought the visitors to the club ground. Despite the unsettled state of the weather, it did not damp the spirits of the true sportsmen, and the large number present had the satisfaction of witnessing a well-arranged athletic programme, some of the items being very closely contested. The valuable prizes were distributed by Mrs. Crompton.

King's Lynn.—The engineer's last report states that since the last meeting applications had been received for 178 8-c.p. lamps, including two small motors, making a total of 12,392 lamps from private consumers. Two Nernst lamps had been fixed for trial in the streets, one at the corner of New Conduit-street and one at the East gates. It is stated that these lamps give 66 c.p., or double the light, at about one-fifth less current than the ordinary lamps. Up to the present they are working satisfactorily, and have required no attention. Another 12 are to be obtained. The working expenses for the month of April, as compared with the same month last year, are stated as follows: units generated 21,909, last year 19,618; units sold to private consumers 6,645, last year 3,080; units sold at power rates 902, last

Digitized by Google

year 14; fuel, stores, repairs, and wages at station (cost of) £120. 6s. 1d., last year £159. 4s. 7d.; cost per unit generated 1·31d., last year 1·94d.; wages of lamplighters and outside staff £15. 9s. 11d., last year £14. 15s. 4d.

Electric and General Investment Co.—We are informed that the directors have decided to recommend the payment of the following dividends, etc., for the year ended May 31, 1902: Ordinary shares—a dividend of 5s. per share, of which 2s. per share was paid on account in December last, leaving 3s. per share to be distributed, and a bonus of 2s. per share; the trustees for the ordinary shares reserve fund propose to distribute out of the proceeds of investments sold and dividends received 1s. per share, making a total present distribution of 6s. per share, or 30 per cent., or a total distribution of 8s. per share, or 40 per cent. for the year. Founders' shares—a dividend for the year ended May 31, 1902, of £50 per share; the trustees for the founders' shares reserve fund propose to distribute out of the proceeds of investments sold and dividends received, £10 per share; making a total present distribution of £60. The above-mentioned payments will be subject to the deduction of income tax. The dividends, if sanctioned by the shareholders, will be paid on July 3, 1902.

Brighton.—On Saturday the Mayor (Alderman Stafford) switched on the current for an electric motor, which has just been installed at Brill's Baths to supersede the steam-pump hitherto in use for supplying the baths with sea-water. The electric installation enables the pumping to be done in one-third of the time occupied by steam and at about one-fourth of the cost. The motor is provided by the Corporation. Alderman Stafford, congratulating the directors of Brill's Baths on availing themselves of the Corporation current, mentioned that a large establishment, by using the municipal supply instead of paying for a separate installation, was saving £700 a year. Mr. H. P. Parshall has been engaged by the Corporation to investigate the difficulties which have arisen with regard to the charges for current by the Lighting to the Tramways Committee. The Tramways Committee, who get their current in bulk from the Lighting Committee, complain that they are charged 1½d. per unit for their supply, and, on this basis, they last quarter paid to the Lighting Committee £1,485. 18s. 7d.

Presentation. — To celebrate the completion of the British Insulated Wire Company's contract for the installation of the Glasgow Corporation telephone department's underground work, the company's resident superintendent, Mr. A. C. Devey, has been presented with a handsome silver cigarette case by the chief members of the telephone department, the presentation being made at the central exchange by Mr. John Macfee, deputy manager. On the same occasion, Mr. J. C. Jones, assistant superintendent, on behalf of the company's local staff and workmen, presented Mr. Devey with a pair of statuettes and a silver cruet as a souvenir of the cordial relations existing between them. The work just completed comprises 100 miles of underground 3in. cast-iron pipes, and about 150 miles of cable equivalent to approximately 30,000 miles of single wire. This is the second largest underground telephone system in the world, the Post Office system in London taking the first place. Glasgow can, however, claim to have installed the largest telephone cable ever made. This cable being too large to go into the 3in. pipes, is accommodated in a 6in. pipe.

Post Office Telephones.—Some time ago representations were made to the Post Office by Mr. W. F. D. Smith as to the delay in connecting subscribers to the new telephone service of the Department, some of whom in the Strand district have been waiting for six months to be place on the Post Office lines. Mr. Austen Chamberlain has replied that about 1,650 telephones are working in connection with the central exchange in Queen Victoria-street. In Fleet-street and the Strand the main cables for subscribers' lines were laid and completed some time ago, but in order to avoid unnecessary opening the footways in the busiest thoroughfares, arrangements have had to be made to transfer the telegraph wires in the existing pipes under the pavement to other routes, so as to make these pipes available for the distribution of telephone wires. The work is of a difficult and complicated nature, but it is hoped that it will be completed along Fleet-street and the Strand in the course of three weeks or a month. As soon as this has been done the work of connecting the premises of subscribers in the Strand district with the main lines of telephone wires will proceed very rapidly.

Swansea.—We note that applications for power from private consumers are coming in very quickly. One firm alone is applying for 230 h.p. Up to the present an effort has been made to keep consumers from coming on owing to shortness of plant, but now the work of installing 2,600-kw. sets is well advanced applications are coming in quicker than they can be dealt with. The amount obtained for private lighting is 3·54d. From Mr. Prusmann's first year's report the works' cost and total costs appear very satisfactory. A deficit of £349, even when excluding sinking fund for the present year, and making no allowance for depreciation, is not a bad result to obtain at the end of the first year, with an average price of only 3·54d., with no tramway load, and practically no day load whatever. It is expected that the second year's working will bring the undertaking very near turning the corner, if it will not actually show a profit. A report by the electrical engineer on the police telephones has been approved recommending that the whole service should be renewed—instruments and connections—and that a central exchange be established, at a cost of £130 to £150, to connect the 15 stations.

Croydon.—The appointment of Mr. A. C. Cramb, of West Hampstead, as chief assistant electrical engineer has been confirmed. Application is to be made to the Board of Trade that the Board should appoint an electrical inspector under the Croydon Corporation Electric Lighting Order, 1890; at the same time suggesting that Mr. Hugh Erat Harrison, of the Electrical Standardising Institute, Faraday House, be nominated by the Council for the appointment upon the following terms of renumeration: Examination of meters in London—single meters, 10s. 6d. each; from two to 12 meters, 8s. 6d. each; each meter beyond 12, 7s.; experimenting upon and reporting on sample meters, £1. 1s. each. Certifying of meters—inspecting and testing at Croydon, £2. 2s. per day, in addition to expenses. Retaining fee as electric inspector—£25; the retaining fee, however, merges into the above stated fee, so that until the sum due for tests, etc., exceeds £25 no charge is made to the Corporation beyond this fee. Mr. D. Cowan, station superintendent at the electricity works, is to receive a bonus of £20, as an equivalent for loss of house accommodation for about 18 months, and when the house now being built is occupied by Mr. Cowan a rent of 5s. a week will be charged, Mr. Cowan to receive electric light free of charge.

Belfast.—The accounts of the electric lighting department for the year ending March 31, 1902, show that the output has increased from 908,067 in 1900-1901 to 1,206,699 in 1901-1902, or about 33 per cent., and the lamp connections have increased in the same period from 79,000 to 98,000 8-c.p.'s, which included 900 h.p. in motors. The average price obtained has been reduced from 3¾d. to just under 3½d., over 20 per cent. of the current sold being at motor prices. The cost figures have all been reduced, with the exception of maintenance, which is higher than the previous year, this being due to heavy expenditure to repairs to buildings due to the storm last winter and reconstruction of a portion of the main flue. The committee consider it good policy to keep everything in good repair out of revenue. The gross profit on the year amounted to £9,053. 19s. 1d., the interest and sinking fund, etc., absorbing this, and leaving as net result a deficit of £347. 7s. 7d., which is being brought forward to next year. The interest and sinking fund are heavy in comparison with the revenue, owing to the fact that very large extensions of plant and mains have been carried out which will not be remunerative for some time to come. Further extensions for the supply of power to some of the large shipbuilding yards are in hand, and it is expected that the motor connections and output will be doubled during the present year.

Jarrow.—The County of Durham Electric Power Distribution Company are erecting temporary works in connection with which Mr. W. E. Tooth is the resident electrical engineer. The plant will consist of Fraser dry-back marine type boilers of 140lb. pressure and two 75-h.p. Brush Universal engines of 380 revolutions, direct coupled to two Brush direct-current bipolar dynamos with a total capacity of 100 kw. E.P.S. accumulators, with a normal output of 194 kilowatt-hours and a maximum discharge rate of 280 amperes, will be installed. Triple-concentric feeders are to be used, laid solid, also three-wire direct-current three-core distributors laid solid. It is proposed to charge for lighting 7d. per unit per first 100 hours per quarter and 1d. afterwards, and for power 4d. and 1½d., with discounts rising from 6½ per cent. for a consumer with 16 per cent. load factor to 41 per cent. with 52 per cent. load factor. The main buildings have been erected with sufficient accommodation for five 500-kw. motor-generators. Power will be supplied in bulk by the Newcastle Electric Supply Company at 10,000 volts. A cable laid in a disused coal mine will convey the current across the River Tyne from the north to the south side. The price charged by the Newcastle Company will be £3. 10s. per annum per kilowatt of maximum demand, and ·35d. per unit for all energy supplied. This is equivalent to 2·65d. per unit for first hour's maximum demand, and ·35d. for succeeding units.

London County Council.—The Council on Tuesday agreed to lend the Bermondsey Borough Council £13,925 for electric lighting and dust destructor works. Notice of intention to lay mains, etc., were approved as follows: Blackheath and Greenwich District Electric Light Company (two transformer boxes and mains in connection therewith in Tranquil-vale, and low-tension mains along a portion of Coleraine-road, St. John's-park, along Lee-road, across High-road, and along portion of Eltham-road); Kensington and Knightsbridge Electric Lighting Company (mains along Glendower-place and Pelham-street); Notting Hill Electric Lighting Company (mains along Clarendon-road); Brompton and Kensington Electricity Supply Company (low-tension mains along Cromwell-crescent and Westgate-terrace); Charing Cross and Strand Electricity Supply Corporation (mains along Crown-court, Martlett-court, and portion of Strand and Strand-lane); County of London and Brush Provincial Electric Lighting Company (low-tension mains along Martin's-road, Lamb's Conduit-passage, Oxford-road, Putney Bridge-road, High-street Putney, and Upper Richmond-road); Metropolitan Electric Supply Company (low-tension mains along Gloucester-place, Dorset-street, Manchester-street, South-street, North-street, Montagu place and square, Bryanston-square, and high-tension mains along Loudoun-road); St. Pancras Borough Council (mains along St. Mark's-square, Cromer-street, and a portion of Windmill-street); London and Brush Provincial Electric Lighting Company (transformer box in Lambeth-road and low-tension mains along Burbage-road); London Electric Supply Corporation (mains of high and low tension along Tooley-street, Tower Bridge-approach, Horselydown-lane, Gainsford-street, and Queen Elizabeth-street); Westminster Electric Supply Corporation (mains across Bridge-street and along a small portion of the Victoria-embankment); and from St. Pancras Borough Council (mains along Gower-street and London-mews). Notices to lay mains, served under orders granted to local authorities, were received as follows: Battersea Borough Council (New-road); Hampstead Borough Council (Redington-road, East Heath-road, Albion-road, Cressy-road, Holford-road, Minster-road, King Henry's-road, Priory-road, and Sarre-road); Islington Borough Council (portion of Cloudesley-square, City-road, Colebrooke-row, Grosvenor-road, Wallace-road, and Petherton-road); Stepney Borough Council (Vallance-road, New-road, Well-street, Goulston-road, and Brick-lane); Woolwich Borough Council (portion of Villas-road).

Coronation.—From the explanation accompanying a handy map recently published in the *Daily Telegraph* we extract the principal electrical features. There will be a number of banks, insurance, and other offices in Threadneedle-street (where there is a celluloid display),

Digitized by Google

Cornhill, Lombard-street (old bankers' signs reproduced), Gracechurch-street, and Bishopsgate-street (fine shows by banks). Foreign bankers in the City make exceptional efforts. There is also the Peace design in King William-street, the Monument with its searchlights (by Pain), effective river reflections from the buildings at London Bridge, and the festooning of the bridge itself in lamps. Broad-street Terminus is also to be worth seeing, and in Cheapside (Peel's Statue) and Cannon-street illuminations are in hand. The Guildhall should be seen. In the City the crowd will "keep to the right." Proceeding westwards by the direct route, Ludgate-hill, Fleet-street, and the Strand have numerous displays by banks, assurance offices, and newspaper offices. The Westminster Town Hall will offer a new departure in electric illumination. On the northernly route the illuminations begin at Holborn-circus, and there is a celluloid show near Holborn Bars. From Blackfriars Bridge along the Thames-embankment there should be noted the electric crown over the statue of Queen Victoria at Blackfriars Bridge, the display of the City of London School, and the Embankment and Gardens as far as Westminster Bridge, in which 20,000 lamps will be employed. Waterloo Bridge will have 2,500 electric lamps. There is a special display in Parliament-street (London and North-Western Railway Company's offices), giving the equivalent of over 4,000 8-c.p. lamps; the series of Agent-Generals' offices in Victoria-street; the Government Offices (mostly Royal emblems) in Whitehall; the London County Council decorations in Spring-gardens; the Cockspur-street shipping offices' transparencies; the clubs in Pall-mall (largely gas flambeaux); and the Royal Palaces and residences: Marlborough House, York House, St. James's Palace, Clarence House, with Stafford House and Bridgewater House, facing the Green Park. St. James's-street will be controlled by the new Metropolitan Police system of circulating crowds. In the vicinity are the St. James's-square decorations. Albemarle-street (Defries) will give a uniform decorative effect at night. Special features will be found in Grosvenor-square, Berkeley-square (Lansdowne House), Piccadilly (particularly Devonshire House), Regent-street (Royal tradesmen's crystal devices), and at Oxford-circus, besides displays in New Bond-street, Conduit-street, and connecting thoroughfares. Lying westwards of Buckingham Palace this area includes a number of displays in Belgrave, Lowndes, Eaton, and Chester squares, with Grosvenor-place and Hyde Park-corner, near to which is Lord Rothschild's residence. The squares are sure to be worth visiting. Chester-square will have fairy lamps. The West-end is to have a unique illumination of the new Westminster Cathedral with electric lights on the evenings of the 26th and 27th inst. Among the devices employed will be a powerful searchlight to be worked from a scaffolding 282ft. from the ground. There will also be two enormous crowns, containing some hundreds of electric lights. The work has been entrusted to Messrs. Donnison, Berlyn, Sillem, and Co. by the Duke of Norfolk on behalf of the Catholic Union of Great Britain. In addition to the illuminations mentioned, a number of others are in preparation.

PROVISIONAL PATENTS, 1902.

JUNE 5.

12817. Improvements in or relating to electric switches. Maunsell Mercier and William Osborne Andrews, 57, Barton-arcade, Manchester.

12823. Improvements in electrical measuring instruments. Arthur Cecil Heap and William Oliver Smith, Century Works, Lewisham, London.

12846. An improved controller and switch for electric motors. John Bush and Matthew Thomas Medway, 90, Lausanne-road, Nunhead, London.

12857. Improvements in and relating to storage batteries. Walter Edward Winship, 60, Queen Victoria-street, London. (Complete specification.)

12870. Improvements in or connected with apparatus for charging electric accumulators. Société Lespagnol et Mériguet, 23, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Nov. 14, 1901, being date of application in France.) (Complete specification.)

12881. Improvements in electric resistances and safety fuses. George Henry Faweus, 53, Chancery-lane, London.

JUNE 6.

12951. Improvements relating to electromagnetic switches. Oscar Schwimmer, Ignatz Schön, and Max B. Schwimmer, 45, Southampton-buildings, Chancery-lane, London.

12956. Improvements in transmitting apparatus for electric telegraphs. Philip Middleton Justice, 55, Chancery-lane, London. (The Rowland Telegraphic Company, United States.) (Complete specification.)

12958. Improvements in switches for electric motors. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12959. Improvements in machines for winding insulating tape on the coils of electrical apparatus. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

12960. Improvements in electrical conductors. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (General Electric Company, United States.)

JUNE 7.

13037. An improved coin-freed machine or apparatus for administering electricity. John Jofeh, 8, Quality-court, Chancery-lane, London.

JUNE 9.

13064. An improved electrical fire-alarm. Robert Wailes Cooke and John Scott, Akenside-hill, Newcastle-upon-Tyne.

13074. A patent automatic electric heating apparatus for governing incubators. Frederick Tomlin, 124, Chancery-lane, London.

13082. An improved combined electrical switch and cut-out for street poles and the like. Max Railing and John Hillery Collings, 71, Queen Victoria-street, London.

13088. Improvements in electric arc lamps. Robert Hopfelt, 53, Chancery-lane, London.

13115. Improvements in wireless telegraphy. Jocelyn Home Thomson, 323, High Holborn, London.

13119. Improvements relating to electrical testing apparatus. David Perret, 45, Southampton-buildings, Chancery-lane, London.

JUNE 10.

13154. Improvements in and connected with electromagnetic annunciators for telephonic or similar purposes. Hermann Oppenheimer, 55, Redcross-street, Barbican, London. (Actiengesellschaft Mix und Genest, Germany.)

13164. Improvements in regulating electric light circuits, specially applicable to the lighting of trains. Henry Leitner and Richard Norman Lucas, 44, St. Martin's-lane, London.

13170. Trolley wire support. Ebenezer Hill and Ebenezer Hill, jun., 52, Chancery-lane, London. (Complete specification.)

13171. Trolley wire support. Ebenezer Hill and Ebenezer Hill, jun., 52, Chancery-lane, London. (Complete specification.)

13175. Improvements in equalising appliances for interconnected polyphase-current systems. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.) (Complete specification.)

13181. Improvement in the current collectors or trolleys of electric railway and tramcars. Jasper Wetter, 37, Essex-street, Strand, London. (Paul Pfeiffer, Germany.)

13205. Improvements in or relating to electric clocks or time-pieces. Josef Bühler, 111, Hatton-garden, London. (Complete specification.)

15207. Improvements in or relating to electric telephotographic or reproducing apparatus. Alfred Julius Boult, 111, Hatton-garden, London. (Laurent Semat, Egypt.)

JUNE 11.

13255. Improvements in electrical measuring instruments. Arthur Cecil Heap, Century Works Lewisham, London.

13267. Improvements in and in connection with fusible electric cut-outs. William P. Burke, 17, Bromley-street, Commercial-road, London.

13275. Improved safety device for electric railways. Edward Parry and Frederick William Bidder, 6, Bream's-buildings, Chancery-lane, London.

13291. Electrical apparatus for indicating time at various places from a principal timekeeper. Léon Kusnick, 47, Lincoln's-inn-fields, London.

JUNE 12.

13297. An improved trolley head, arm, and posts for overhead electric wires, and a safety appliance for rendering broken electric wires harmless. Jasper James Carter, 4, Vergemont Hall, Clonskeagh, co. Dublin.

13308. Improvements in or appertaining to lifeguards for electric tramcars or the like. Dionysius Newton, 9, Tempest Hey, Liverpool.

13328. An intensive electric and solar furnace. Adeline Paget, 41, Devonshire-street, Portland-place, London. (Newton W. Emmens, United States.)

13357. Improvements in connection with trolleys for electric tramways or railways. The British Thomson-Houston Company, Limited, and Frederick Samuelson, 83, Cannon-street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published July 3.

1901.

4863. Combined electromagnetic and carbon microphone. Rossetter.

9959. Incandescent electric lamp globes. Bohm.

11552. Automatic self-locking lifeguards for electrically-propelled cars or other vehicles. Hudson.

12089. Automatic electrical signalling apparatus for railways. Spagnoletti.

12094. Electric cables. Tremain.

12121. Fluid pressure machinery for pressing together the copper segments and insulating strips of electric commutators and for compressing the discs of armatures. Petch.

1902.

947. Apparatus to give alarm by mean of an electric bell in the event of a locomotive running past a signal at danger. Chubb.

1136. Electrodes for arc lamps. Gebr. Siemens und Co. and Viertel.

NOTES.

Wireless Telegraphy in Alaska.—We learn that the Marconi Wireless Telegraph Company have entered into a contract with the United States Government to instal their system in Alaska, to connect Fort Davis with St. Michael's, an uninterrupted distance of 108 miles. The installation is estimated to cost about £2,000.

An Electric Combine.—It is announced that an offer has been made by the General Electric Company of America to acquire control of the Sprague Electric Company. According to the information received, the first-named company propose to obtain the controlling interest in the Sprague concern principally by the exchange of securities. The capital of the Sprague Electric Company is given at £1,000,000, and that of the General Electric Company, which recently increased its capital stock, at £9,000,000, so that the combined capital of the amalgamated houses will be 10 millions sterling.

American Association.—We have received a preliminary announcement of the fifty-first annual meeting of the American Association for the Advancement of Science, which opens to-morrow at Pittsburg, in the United States. The conference will be continued the best part of next week, and the several affiliated scientific societies will hold their sessions in Pittsburg at the same time. Elaborate arrangements have been made for the reception of the members and their friends attending the convention, and some very important papers are expected to be contributed by prominent scientists of the day.

Cable Rates.—It is only a natural consequence that as time goes on the rates enforced by the telegraph companies should be steadily decreased to within reasonable limits, but it is especially noticeable in the past six months that reductions in tariffs to all parts of the world have come upon each other with remarkable rapidity. The latest company to follow this lead is the Western Telegraph Company, who have announced a reduction of the cable rates to British and German West Africa. From the 1st prox. the following reductions to these places will apply: Lagos, from 6s. 5d. to 6s. 3d. per word; Brass, 6s. 7d. to 6s. 3d.; Bonny, 6s. 10d. to 6s. 3d.; Lagos Government stations, 6s. 7d. to 6s. 5d.; Cameroons, 7s. to 6s. 5d.

Rontgen Society.—The following is the list of officers and council for the ensuing year, who will be balloted for at the annual meeting of the society on July 3: President—Mr. Herbert Jackson, F.C.S.; vice-presidents—the Right Hon. Lord Blythswood, the Right Hon. the Earl of Crawford, K.T., Messrs. J. Mackenzie Davidson, M.B., D. Ferrier, M.D., F.R.S., J. H. Gladstone, D.Sc., F.R.S., and Dawson Turner, M.D.; council—Messrs. G. B. Batten, M.D., Barry Blacker, M.D., Wm. Chattaway, J. H. Gardiner, F.C.S., A. W. Isenthal, F.R.P.S., the Rev. P. Mulholland, B.A., Messrs. E. Payne, M.A., C. E. S. Phillips, G. H. Rodman, M.D., E. W. H. Shenton, L.R.C.P., H. Snowden Ward, F.R.P.S., and J. Wimshurst, F.R.S.; hon. treasurer—Mr. J. J. Vezey, F.R.M.S.; and hon. secretary—Mr. F. Harrison Low, M.B.

Machinery Users' Association. — The annual general meeting of the above association was held on Thursday, the 19th inst., at the Westminster Palace Hotel. Sir W. H. Houldsworth, Bart., M.P., presided, and in moving the adoption of the report and accounts referred to the improved position in which the association stood owing to the report of the Royal Commission on Local Taxation and of the recent judgment of the Lord Chief Justice in the case of Crockett and Jones and the Northampton Union Assessment Committee. A recent decision in Scotland, adverse to the manufacturers, had brought a great amount of Scotch support to the association. Mr. Lewis Evans referred to the question of water supplies as being a most important one for manufacturers, while Mr. W. H. Holland, M.P., spoke with approval of the formation of the Commercial Committee in Parliament.

Auto-Decoherers.—The question of self-decohering coherers is discussed by Mr. M. A. Rochefort in a note to the French Academy. It has been stated that the difficulty of regulating auto-coherers is due to the fact that the limits between the imperfect contact, not quite at the cohering stage, and the imperfect contact which will cohere but requires tapping, are too close to allow a self-righting coherer to be made with imperfect contacts. The author shows that every self-righting coherer may be transformed into one of the ordinary kind by diminishing the pressure on the filings. He is not, however, yet prepared to state whether the converse holds true. Great practical improvement is believed to attach to coherers which automatically decohere. By slight modifications of the soft-iron coherer, the author has succeeded in using it in wireless telephony experiments. These coherers may be regulated by an external magnetic field with great advantage and certainty.

Galileo Ferraris Award.—The Committee for the "Galileo Ferraris Award," which was instituted in 1898, have determined to open an international competition for the award of the above prize on the occasion of the unveiling of the monument to that illustrious scientist in Turin in the month of September next. The award is of 15,000 Italian lires (£600) together with the compound interest thereon accumulated since the year 1899 up to the day of the award, and will be granted to the inventor of some practical application of electricity from which some noteworthy progress may arise. Competitors may produce either pamphlets, schemes, and drawings, or machines, apparatus, and contrivances concerning their invention. The jury, composed of the committee, shall have full power to cause practical experiments to be made upon the inventions entered for competition, and upon the relative apparatus, contrivances and machines. Competitors are to file their application and deliver their works, machines, apparatus and whatever appertains to their invention not later than 6 o'clock p.m. on Sept. 15, 1902, at the office of the Secretary of the Committee, care of the Administrative Committee of the First International Exhibition of Modern Decorative Art in the buildings of the Chamber of Commerce and Art, 28, Via Ospedale, Turin, Italy.

Manufacture of Atmospheric Products.—We understand from the *Western Electrician* that a process is being exploited at Niagara Falls for the fixation of nitrogen, investigation, it is said, having determined that a high-voltage direct current, made to arc in a particular manner in a closed chamber, will convert air into nitrogen trioxide, giving a large yield. The result is the formation of a powerful company to make atmospheric products at Niagara on a commercial scale. It is given out that in the process a chamber about 10ft. high is used, into which is led cool, dried air. This air is made to pass through a region where electric arcs are continually discharging, the arcs being of light current and heavy voltage. It is about these arcs that the chemical transformation takes place, the air becoming a brownish-red, gaseous substance—trioxide of nitrogen. From the enclosed chamber the gas is led to an absorption tower, where it is brought into contact with whatever substance of which a nitrate is desired. Thus, it is said that by leading the gas through pure water pure nitric acid results therefrom. If brought into contact with caustic potash, the product becomes salt-

Digitized by Google

petre, and in contact with caustic soda, the product formed is Chili saltpetre. Lord Kelvin, when he was in the States a short time ago, is reported to have spent a few hours in the experimental plant at Niagara, and is accredited with having given his verdict in favour of the success of the process.

Electrical Engineer Volunteers.—We note that the possible formation of a corps of Electrical Engineer Volunteers is being widely discussed in the States just now. The immense value of such a body of men, trained in the art of electrical science, as an auxiliary force to an army on active service was amply proven by the excellent work done by our Electrical Engineers in the field during the late war. The scheme was discussed at a recent meeting of the American Institute of Electrical Engineers, and not only met with the approval of the members generally, but was also welcomed by General A. W. Greeley on behalf of the United States army. In his remarks before the institute, this officer truly said that in military affairs electricity could probably play to-day even a more important part than it does in civil affairs. The increasing complexity and scope of electricity make it impossible for the soldier or the sailor to have a proper working knowledge of the subject, and this alone renders the services of a technical corps invaluable, especially in time of war. It is believed that an Electrical Engineer corps in the States would be very popular, and that the military authorities would do all in their power to encourage its formation and admit it, possibly, to field manœuvres, as is done in this country. By the way, we note that our corps of Electrical Engineer Volunteers are to undergo their annual training this year, by detachments, at Deal, Bexhill, Harwich, Gravesend, Portsmouth, Isle of Wight, Sheerness, Milford Haven, Plymouth, and Falmouth.

A Motor Compensator.—Mr. C. P. Steinmetz was last month granted a patent in respect of an alternating-current motor compensator, the object of which is to reduce the starting torque of a synchronous or induction motor only in proportion to the reduction of current taken from the mains, the torque per ampere of the main current remaining unchanged. After the motor is started the regulator can be adjusted so as to raise the voltage at the motor terminals until full voltage is reached. The regulator comprises a magnetic structure consisting of a fixed and a movable part, provided with compensator coils, one for each phase when used on a polyphase circuit. The compensator coils are connected across the mains, and the motor or other regulated circuit is connected to corresponding intermediate points in these coils. The coils have a series branch or portion in series with the load, and a shunt branch or portion in parallel with the load. One form illustrated for use in connection with a three-phase motor consists of a six-pole ring, every alternate pole having coils. Within the ring is a movable magnetic iron shuttle with three poles. By changing the relative positions of the poles of the shuttle the magnetic circuit can be varied so as to include both the series and the shunt branches of the compensator coils in a closed magnetic circuit, and therefore in a position to transfer energy from one branch to the other; or to withdraw the series shunt branches from inductive relation by opening the circuit of the series branches and leaving the magnetic circuit with the shunt branches closed.

Powerful Electric Discharges.—The issue of the *Electrical Review* of New York for the 31st ult. prints a short communication from Prof. John Trowbridge relative to an observation made by him upon the spectrum of an exceedingly powerful electrical discharge through the ordinary vacuum tube used in the study of the spectra of gases. In the employment of a battery of 20,000 cells to charge glass condensers he found that glass plates less than $\frac{1}{8}$in. in thickness could not be used, for the sudden rush of a powerful charging current was sufficient to break down an insulation which would resist several hundred thousand volts accompanied by a weak charging current. Moreover, it was not safe to build up the condensers made of glass plates, even of $\frac{1}{8}$in. in thickness, in a compact form, for the plates, under the tension of 20,000 volts, broke down, possibly from the effect of gliding discharges over the glass surfaces from the edge of one coating to that of another, although the distance was made far greater than one would suspect should be traversed by such anomalous discharges. Under the conditions of the experiments the discharges rose to values of 10,000 amperes for about one millionth of a second. In these circumstances the ordinary Plucker tubes used were destroyed after a few discharges, and immediately became coated inside with a white deposit of sodium salts coming from the glass. The interesting point, however, is that the resulting spectrum contained dark as well as bright lines—an evidence of selective reversibility of the silver salt, which is of great importance in conclusions drawn from the study of astronomical photographs. Concluding his communication, Prof. Trowbridge states that a tube filled presumably with dry hydrogen gives after a few powerful discharges, when subjected to feebler alternating currents, the spectra of argon. These arise probably from the dissociation of a trace of residual air in the process, of the dissociation also of water vapour always present in glass tubes, together with the presence of an alkali like sodium.

Electric Block Signalling.—At the recent Moscow convention of the electrical engineers of Russia several propositions were put forward for the solution of certain problems in the electric blocking of trains, and of the many systems submitted there was one which met with more favour than any of the others. The action of this particular system is similar to that of most of other proposals brought forward, being based on the ductility of the rail, but it uses to better advantage the characteristics of the rail on the approach of a train. From an illustrated description of the favoured system in the *Electrotechnic* of St. Petersburg, we gather that the method employed is as follows: On two adjacent sleepers a beam of charcoal iron is fastened. In the middle of the space between the sleepers a box is fastened vertically to the beam. This box contains an arrangement of levers required for the transmission of the motion and for the formation of a contact. It has also an opening for the introduction of an insulated cable for transmitting the current, and another opening, containing a pin, for the transmission of the bending motion of the rail to the apparatus. The beam, as well as the box with the mechanism, has an immovable, fixed position, independent of the position of the rail. In the middle of the space between the sleepers is fastened tightly to the base of the rail a brace which has a spring that reaches below the pin. Under the normal inactive position of the device, the rail brace and pin have the position of rest with a percussion screw resting on the pin. As soon as a train approaches, the rail and the pin commence to move, and the whole system, finding no resistance, will permit the arm of a lever, with its weight, to drop slowly downward till a connection with the lower contact is established. The current is thus allowed to pass from the cable into the lever and the earth. While the pressure on the rail is continued the established contact remains. When the rail returns to its normal condition, which naturally takes place when the

Digitized by Google

train has passed, the whole system at once comes to its position of rest. In case the train should remain standing on the rail, the ductility of the rail comes into evidence and brings the device into action.

Train-Lighting by Electricity.—Further progress in the adoption of electrical apparatus for train-lighting in Germany is noted in a consular report from Berlin. For the past 15 months the German railway engineers have been making experiments with various forms of electric lighting, the net result of which was recently reported to the Association of German Mechanical Engineers by Mr. Wichert, the chief of construction. In his communication Mr. Wichert traversed descriptively the experience of the Prussian Administration with the several methods of car-lighting, from candle to electricity. From the standpoint of the technical engineer, the axle-driven dynamo, located in each car and making each an independent unit, is the ideal system. In addition to the dynamo, the method requires only a small auxiliary storage battery to feed the lights while the train is at rest, and a regulator to equalise the current during the different rates of speed attained when running. But one of the principal objections to this system, without considering the space occupied, is that it is inseparable from the jarring, grinding noise of the dynamo, which has not yet been reduced to a point where it ceases to annoy the passenger. The second method tested in Prussia is that with large storage batteries located in each car and fed from electric plant at terminal or other stations. This system has the advantage that it does not consume any power from the locomotives, and makes no noise or vibration; but its most obvious disadvantage is that storage batteries of sufficient capacity to carry a current supply for a long run are heavy and costly, and the process of charging them involves delay and special apparatus. For these reasons, therefore, the Prussian State Railway Administration have settled upon a compromise between the two foregoing methods—viz, a system by which a steam-driven dynamo is placed on the locomotive, which supplies current to a small regulating storage battery in each car of the train. According to the report above referred to, this system meets more perfectly than either of the others all the requirements of the passenger train. It is now being installed on many of the State railways in Prussia. In the distribution of lights each compartment in a first or second class car has a ceiling lamp, controlled by the attendants, and four reading lights at the sides of the carriages, which can be turned on or shut off at will by the passengers.

Tramways Congress in London. — Preliminary details of the arrangements for the holding of the Tramways and Light Railways Congress at the Agricultural Hall, Islington, next week have already appeared in this journal, and we would only remind our readers that the convention will be opened by Mr. Gerald Balfour at 12 noon on Monday, the 30th inst. Immediately after the ceremony the Tramway and Light Railway Exhibition will be formally inaugurated in the main building of the Agricultural Hall. We have, however, received a list of the papers which will probably be read and discussed at the business meetings of the congress on Tuesday, Wednesday, Thursday, and Friday, these proceedings being timed to commence at 9.30 in the morning. The titles of the papers, the majority of which are contributed by the foreign delegates from the Union Internationale Permanente de Tramways, are as follows: "Transfer Tickets" (correspondence), by Mr. Lavallard, manager, Paris Omnibus Company; "Narrow *v.* Ordinary Gauge," by Mr. C. de Barlet, general director of the Belgian Light Railway Company; "Brakes," by Mr. Poetz, engineer-in-chief of the Hamburg Tramways Company; "Proposed Basis for Estimating Powers of Motors," by Dr. G. Rasch, of the Polytechnic School, Aix-la-Chapelle; "Conditions under which Tramways may be laid on Roads," by Mr. A. Janssen, general secretary of the Brussels Tramways; "Laws Regarding Tramways and Light Railways," by Mr. R. H. Scotter; "Car-Sheds," by Mr. Trantweiler, engineer-in-chief of the Strassburg Tramways Company; "Traction Systems," by Mr. Ziffer, director of several Austrian light railway companies; "Profitable Employment of Rolling-Stock," by Mr. J. H. Heiszen, manager of the Amsterdam Corporation Tramways; "Central Stations," by Mr. Ch. Thonet, director of the General Contract Company of Liège; "Cost of Electric Energy," by Mr. Ch. Thonet; "Underground (Tube) Railways," by Mr. P. W. McMahon, chief engineer of the City and South London Railway; "Carriage of Luggage, Goods, and Mails," by Mr. G. Marshall, manager of the Brella Light Railways; "Heating of Cars," by Mr. Peiser, chief engineer Great Berlin Tramways Company; and "Report by Messrs. L. Janssen and Geron on a Uniform System of Accounts." There will also be various other communications presented for discussion. The banquet to be given by the Tramways and Light Railways Association to the foreign members of the International Tramways Union will take place at De Keyser's Royal Hotel, Victoria-embankment, on the night of Friday, the 4th prox.

The Light Railways Act.—The report of the Ligh Railway Commissioners for last year, which has just been issued, affords ample food for reflection. Perhaps the most striking feature about the document is the fact that the number of applications for orders under the Light Railways Act is still on the decrease. The actual figures are interesting. Thus, in 1896, the first year of operation of the Act, there were 56 applications for orders; in the next year, 1897 98, there were 65; in 1898-99 the number was 94. The year 1899-1900 brought this figure down to 67, and in 1900-01 this was further reduced to 53—less, even, than in the first year. These figures speak for themselves, and the reason why promoters of electric traction systems in this country are now fighting shy of procedure under the Light Railways Act is not very difficult to see. As is generally known, the condition precedent to the granting of an application for powers under the Tramways Act, either by Bill or provisional order, is the sanction of the local authority or authorities concerned to the scheme, and if this be not obtained, promoters may just as well keep their money in their pockets as to attempt to get their powers granted. In the Light Railways Act this absolute veto on the part of the local authority to defeat any scheme of which it is minded not to approve is not given, and when the Act first came into operation promoters of these schemes saw, or thought they saw, an opening out of the difficulty of getting the consent of the local authority, and having their proposals considered on their merits. This, no doubt, will account to some extent for the increase in the number of applications to the Light Railway Commissioners in the three years from 1896 to 1900, when the figure stood at 94. This number, as shown above, fell in 1900-01 to almost half, and the natural conclusion is that the Light Railways Act is disappointing in its operation. The important particular in which it has failed to meet with the approval of promoters is obviously that with regard to local veto. Only last week it was admitted by Mr. Gerald Balfour that not only the Board of Trade, but the Light Railway Commissioners, had felt themselves bound by the Tramways Act on this question of local veto, and that the Light Railway Act no longer offered a way of

Digitized by Google

escape out of the difficulty. The result, then, is that whichever procedure be adopted, either under the Tramways Act, by Bill or provisional order, or under the Light Railways Act, the proposals of promoters of private enterprise are subjected to the whims and fancies and often the quite unreasonable obstruction of the local authority. To this, therefore, more than to any other reason, must be attributed the great falling-off in the number of applications to the Commissioners in the past year. What the present year will bring forth it is impossible to say. As a comparison, it may be mentioned that last November 44 new applications were put forward. Those for May, 1902, number 16. The total for 1901-02 is thus 60—only four in excess of the first year's application.

Three-Phase Currents for Traction Purposes.—For a remarkably lucid and concise account of European practice in electric traction with three-phase alternating currents, we would refer our readers to an article by Mr. Carl L. De Neuralt, which he contributes to the *Electrical Review* of New York for the 31st ult. The author there describes in considerable detail the main features of some of the more important railways on the Continent using alternating currents for traction purposes at the present time. Probably the best example of an alternating-current railway installation is that of the Burgdorf-Thun Railway, and the results of some tests made on this line are given, with a few general conclusions as to the applicability of polyphase alternating currents to traction systems. These tests, carried out by Messrs. Siemens and Halske, showed clearly that an alternating-current railway was absolutely feasible, and proved that no serious difficulty would be encountered in regard to the trolley line construction. The total length of the Burgdorf-Thun Railway is 25 miles. The energy is furnished by the power station on the Kander, the primary line voltage being 16,000 and the number of cycles 40 per second. Fourteen transformer stations—the transformers being of the oil-cooled type—reduce this voltage to the voltage in the trolley lines—*i.e.*, 750—this being the limit set by the authorities at the time. Most of the sub-stations are equipped with a small 2-kw. lighting transformer, furnishing current for lighting the neighbouring railway station. The height of the trolley wires above the rails is about 16ft., the contact devices on the cars consisting of four steel frames per car, two on each side of the car roof. The distance of about 30ft. between the two sets of contact devices is just long enough to allow three of the four bars making contact under any condition. The motor-car carries a 64-h.p. three-phase motor geared to each axle. The gear ratio is 1 : 3, and the speed of the motor 600 revolutions per minute, equivalent to a train speed of nearly 25 miles an hour The author also gives an excellent example of the application of three phase currents to tramways in the case of the Lugano system. The total length of the line is about three miles, with maximum grades on long stretches of 3 per cent. and on short stretches of 6 per cent. The transmission voltage is 5,000 volts at 40 cycles, and transformers reduce this to 400 volts in the trolley line. Two trolley wires are used, and the rails serve as third conductor. There is one 20-h.p. motor per car, completely enclosed. The author states that tests have demonstrated that it is possible to start with ease with these motors even on 6 per cent. grades and under more than full load. He also describes the Gornergrat Railway, the Jungfrau Railway, and the Stansstad-Engelberg Railway, in each of which practically the same practice has been followed. The author's conclusion is that there are cases where alternating currents are particularly well adapted to solve the problems under consideration, and where continuous currents could not be advantageously employed. Each special case should therefore be studied for itself, and the decision as to what system should be adopted ought to be dependent on the different conditions which might apply to the particular case, principally profile of the road, speed required, number of stops, and character of the traffic.

Electric Traction on Steam Railways.—The current number of the *Electrical World* abstracts a paper by Huber, in which the problem of electric traction under steam railway conditions is first discussed. At the outset he states his opinion that the electric locomotive must be used on these lines, and the reason which he gives for this conclusion is that, while single cars running at short intervals are suitable for passenger service, electric traction on normal railways has to take care also of the freight traffic, and handle the transfer of heavy freight trains between different main or branch lines. To ensure economy of operation, a high voltage must be used. This tends to make the use of three-phase currents prohibitive, as two overhead contact wires would be required, and they would not be insulated sufficiently to fulfil all requirements of safety. Only a single overhead contact wire can be considered reliable. The author therefore recommends single-phase alternating current for transmission. This alternating current is converted into direct current by a motor-generator placed on the locomotive, and this direct current is supplied to the motors. The direct-current side of the motor-generator is separately excited, which, in the opinion of the author, gives an excellent method of speed regulation, starting and braking, and returning power to the line on descending grades; and he refers to the systems proposed before by Ward Leonard, and recently by Mordey. The Oerlikon Company have worked out the practical details of the system, and have recently made an offer to the Swiss Railway Department to instal the system on a road of its network. A locomotive is being built with four axles, for receiving alternating current at 15,000 volts, for a capacity of 700 h.p. at the drawbar, the total weight being 44 tons. This shows that such a locomotive is not too heavy. To drag a train of 250 tons weight, with a speed of 25 miles, on a grade of 1 per cent., about 505 kw. are required, which for 14,000 volts and a phase difference of 10 per cent. means that 45 amperes are to be taken off from the contact wire. This current is not excessive. The only serious objection of the use of alternating current for traction with rail return is the reactance of the rails, which causes too high a voltage loss, if the frequency is, say, 42 periods (Burgdorf-Thun). The author believes that although the weight and the cost is thereby increased, it will be necessary to use a lower frequency, say 16 periods, and gives numerical calculations which show that the losses are small on a long line which is equipped with this system and on which several trains are running at the same time. The feeding points are proposed to be placed at distances of 120 km. He thinks that a lower voltage than 15,000 is insufficient and a higher voltage undesirable, as 15,000 volts is said to be the highest E.M.F. which can be produced directly in machines with safety and without special difficulties. The Oerlikon Company have worked out a new system of suspending the contact wire, which gives a very great freedom in its alignment; it runs at the side of the road, and the trolley poles slide along it, being movable around an axle in the direction of the car and being pressed upwards by a spring. He claims that the arrangement of the switches becomes very simple. In conclusion, the author expresses the opinion that for traction in general, with the exception of high-speed roads and track and pinion mountain roads, the use of any other but direct current for feeding the motors is wrong.

FORMERS AND FORMER-WINDING.

BY F. W. DAVIES.

(Concluded from page 837.)

VII.—NOTES ON THE DESIGN OF WINDINGS AND FORMERS.

The calculations necessary for the design of the former-windings may now be considered. The principal points involved in their design are the amount of insulation to be used, and, in the case of armature winding, the space required for the ends of the windings. It is well to remember that it is always better to err by allowing too much room for insulation, rather than too little; as tightly-fitting coils are a frequent cause of breakdowns, both in field-magnet and armature coils. With field-magnet coils, a little clearance between the inside of the finished coil and the magnet core should always be allowed, as the core castings cannot be relied upon to come out exactly to the required size. There being plenty of room, there is no valid objection to the very slight enlargement of the coils necessitated by allowing this clearance. The clearance should be not less than $\frac{1}{16}$in. all round the core, and in the larger sizes may be as much as $\frac{1}{8}$in., or even more. Except in very rare instances, the total thickness of insulation on the inside of field-magnet coils need not be more than $\frac{1}{16}$in. This insulation may consist of a layer of flexible micanite, vulcanised fibre, presspahn, or other suitable insulating material, about 25 mils in thickness, which is placed next to the wire round the inside of the coil, and bent over at the ends to insulate the ends of the coil. The whole is then bound over with strong cotton tape in the manner shown in Fig. 3. This brings the thickness of the insulation on the inside of the coil up to about 50 mils. A coil insulated in the manner just described, and afterwards "served" with some good insulating varnish, and then baked, presents a very neat appearance, and is perfectly safe—both electrically and mechanically.

Having determined the clearance between the field-magnet core and the coil, and the insulation on the inside of the latter, it is an easy matter to determine the dimensions of the former for winding it on. The former should be made of the same cross-section as the magnet core, plus the amount allowed for clearance and insulation. Thus, assuming that $\frac{1}{16}$in. is allowed all round for clearance, and another $\frac{1}{16}$in. for insulation, the former must be $\frac{1}{4}$in. larger than the magnet core each way if it is of rectangular section, or $\frac{1}{4}$in. larger in diameter if of circular section.

It is not such a simple matter to determine the amount of insulation necessary, and to calculate the room required, for the coils of an armature. The thickness of insulation to be used must be calculated with more exactitude, as the space is usually very limited; and the armature core, unlike the cast core of a field magnet, may be relied upon for being of the exact size. Armature coils may be insulated from the core either by the plan adopted for the insulation of field-magnet coils—of placing all the insulation upon the coils themselves, and then binding them over with tape, leaving the core bare; or by the older plan of insulating the armature core in the usual manner, and also lightly insulating the coils with tape, this latter usually being done at the ends only. The former plan often proves to be the cheaper as regards labour. It is used by several firms at the present time, and is a plan that has much to recommend it. It is necessary to bind the ends of the coils with tape, whichever method of insulation is adopted, as the tape not only insulates the coils, but serves to bind the component turns of each coil together. Especially is this necessary when there are a large number of turns per coil. When the armature is insulated independently of the coils, the total thickness of insulation on it should be about 40 mils per side for ordinary voltages, such as up to, say, 500 volts. This may be made up of 25 mils of presspahn or flexible micanite (which of these is used will depend upon the voltage), and 12 mils of "Empire" cloth, or varnished calico. The total thickness of insulation will then be about 40 mils *actually*, owing to the fact that the two thicknesses of insulation will not lie perfectly close together. For higher voltages the insulation should, of course, be proportioned to suit. The thickness of the taping at the ends of the coils should be about 12 mils per side. When a plain armature core is used, a strip of insulation, about 25 mils in thickness, should be placed between every coil on the periphery of the core. When the core is uninsulated and all the insulation put on the coils, the first layer of insulation may be in the form of troughs. These troughs, which should be about 25 mils in thickness for armatures up to 500 volts, are placed one on each active limb of the coil. The coil is then carefully taped all over with either strong cotton tape or prepared tape, until the insulation is brought up to the required thickness. The armature end plates should be insulated as usual; also a layer of insulation may be inserted between the two layers of the end windings if the armature is barrel-wound.

The expedient of placing two or more coils in one slot in a slotted armature is one that is occasionally resorted to. When this is done, the insulation between the coils which are thus placed together, need not be very thick. It is convenient to wind such a group of coils as one large coil, placing the necessary insulation between them during the process of winding. The advantage of placing several coils in one slot is that not only is space economised thereby, but the punching of the armature stamping is considerably simplified, owing to the number of slots being reduced. It is not advisable to place more than two coils in the same slot, as the grouping of them together in this fashion tends to complicate both the winding and the connections.

In order to satisfactorily design the former for the armature coils, it is necessary to know four things: the dimensions of the armature core, the pitch of the armature winding, the distance to which the coils will project at each end, and the particulars for the winding of the coils. The dimensions of the core, the pitch of the winding, and the winding particulars (such as the number of coils, turns per coil, and size of wire), are matters that are decided by the ordinary calculations. An explanation of these calculations does not come within the scope of these articles at all, but must be sought in books and articles dealing with designing. The space required for the ends of the winding, although such an important point, has received from writers on electrical subjects but the same scanty consideration that has been accorded to formers and former-winding generally.

With the evolute winding, the distance to which the end windings will project depends upon the permissible thickness of each spiral. When the permissible thickness of the spirals has been determined, it will then be possible—if the armature is wire-wound—to ascertain the best arrangement of the wires in the end spirals, and to decide whether or not the armature will require to be wound in sets in order to get the coils on. From this we can find out the width of each spiral. If the armature is bar-wound the width of the end connectors can very easily be determined, for it is obtained by dividing the required cross-sectional area of the end connectors by their thickness. The maximum *possible* thickness of the spirals for an evolute winding may be obtained approximately by means of the following formula:

$$t = \frac{\pi\, d\, r}{\sqrt{c^2\, r^2 + 10\, d^2\, z^2}}.$$

In this formula, t = the maximum possible thickness of end connector, or spiral, in inches; d = the virtual diameter of the armature core, in inches—the virtual diameter being the over-all diameter of the core in the case of a plain armature, the diameter as measured at the bottom of the slots in a toothed core, and the diameter measured at the bottom of the perforations in an iron-clad core; r = the radial depth of the actual spiral part of the end winding, in inches; c = the number of coils on the armature, or the number of coils in one set, if the armature is wound in sets: $z = \frac{\text{the pitch of winding}}{4} + 2$, the pitch being here taken as one-half of its actual value, if the armature is wound in two sets or one-third if wound in three sets.

It will be noticed that the thickness of the end spirals obtainable from the above formula is the maximum *possible* thickness. It is well, in order to allow for ventilation between the spirals, and also to allow for any irregularities that may occur in the forming of them, that their thick-

Digitized by Google

ness (over the insulation) should be rather less than this The *maximum permissible* thickness (over the insulation) may be taken as ·75 of the *maximum possible* thickness.

The space required for the ends of a bastard winding is not such a definite quantity as that for an evolute or barrel winding, as the form given to the coils is not a clearly defined one. As, however, it is used mainly on small armatures, where the end space is not relatively of such importance, this does not much matter. Roughly speaking, the space required for the end windings is approximately proportional to the virtual diameter of the armature core. For all practical purposes the formula, $e = \cdot 4\, d$ (where e = the distance, in inches, to which the winding will project at each end, and d = the virtual diameter of the armature core, in inches) will suffice for the calculation of the space required.

The end space required for the barrel winding, like that for the evolute winding, can be calculated with a fair amount of accuracy. The following formula shows the method of obtaining the length to which the ends of a barrel winding will project beyond the core:

$$e = \frac{a\left(\frac{t\,y}{4}\right)}{\sqrt{a^2 - \left(\frac{t\,y}{4}\right)^2}} + 3\,r.$$

Here e = the distance to which the winding will project beyond the core at each end, in inches; a = one-half of the length of arc between the two limbs of a coil, in inches; t = the thickness or width of a coil, in inches—measured over the insulation; y = the pitch of the armature winding; r = the radial depth of one limb of a coil, in inches.

The ends of an armature winding of the barrel type are usually supported by means of end plates, which are tapered on the periphery. They are tapered for two reasons: in the first place, the end windings are not so liable to get damaged when the armature is laid down on a bench or on the ground, as it would be if the end windings were flush with the periphery of the armature—specially when a toothed core is used; and in the second place, the whole armature presents a smarter appearance when the end plates are thus tapered. A suitable taper for end plates is 1 in 12. When an armature is wound with a heavy bar winding of the barrel type, the barrel end plates may be dispensed with entirely; as the winding is strong enough to support itself—it being under no strain at the ends, save that due to centrifugal force. It is necessary in such cases to provide a templet at each end of the armature whilst it is being wound, to build up the winding on. Not only is there a slight saving in the cost of manufacture by thus dispensing with the end plates; but the winding keeps cooler, owing to the increase in the area of the effective radiating surface.

Formers of all kinds require to be fixed in some way whilst in use. Formers for the coils of field magnets, wire-wound ring armatures, and wire-wound drum armatures with bastard winding, are held between centres during the process of winding. Block formers for drum armature coils of both the evolute and the barrel types are usually placed on the bench for winding. Formers of the frame type are preferably fixed permanently to the winding bench. Some kinds of frame formers for barrel-type wire-wound drum armatures, instead of being used on the winding bench, are mounted on shafts which are held between centres whilst the coils are being wound, this kind of former being considered by some to offer greater facilities for winding.

The application of a little "French chalk" to a former, especially when it is made up of several separate blocks or pieces, is a great improvement; as it renders it easier to take to pieces, and facilitates the removal of the coils. A little chalk may be rubbed on the adjoining surfaces of those formers which are made up in sections, such as the formers for field-magnet and ring armature coils; the former for bastard-wound drum armature coils. Also a little should be sprinkled occasionally on formers of all kinds, at those places where the wires rub on them when the coils are being removed. By giving these points a little attention most of the trouble and annoyance caused by abraided insulation on former-wound coils may be avoided.

EDMONDSON'S AUTOMATIC LOCKING SIGNALS.

There is no doubt that some efficient system of controlling the running of tramcars and light railways by means of signals on the block principle, without increasing the wages account, is likely to meet the wants of a considerable number of our tramway and consulting engineers, especially where, through force of circumstances, it has been, or is, necessary to lay single track. To put the passing places so close together that the driver can see the next one ahead is, after all, an expensive compromise between single and double track, and useless in foggy weather. What is wanted to meet all requirements must be automatic, simple, and not likely to get out of order, and as such the system we propose describing in this article merits attention. The signal consists of an oblong box or case containing the mechanism, and having a shaft or spindle projecting through one side, to which the semaphore

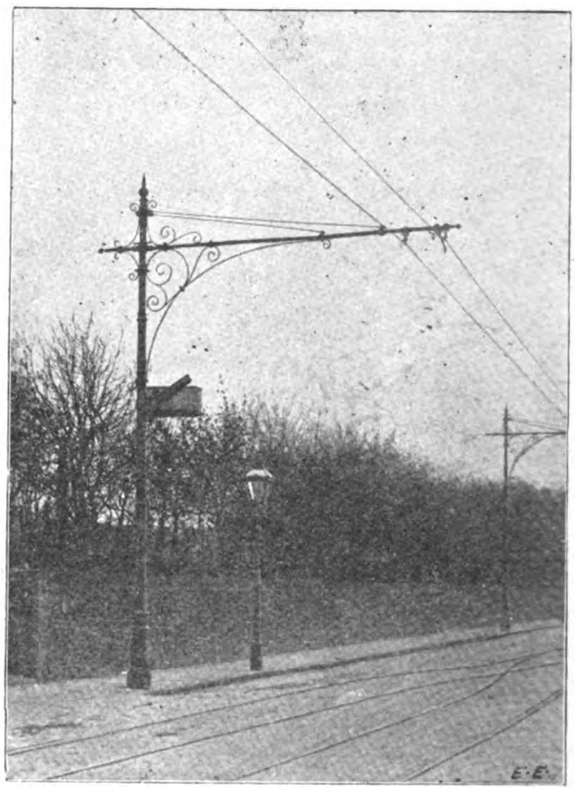

FIG. 1.—The Edmondson Automatic Tramway Signal.

arm is fixed on the same shaft, but inside the box is keyed a crossbar, on each end of which are suspended two iron cores. These iron cores hang within solenoids fixed to the base of a cast-iron frame, to which all the mechanism is attached, and are used to pull over the crossbar and semaphore arm to "Danger" or "Line clear," according to which solenoids are energised. Whichever position the semaphore arm is in it is effectually locked. If at "Danger" it cannot be put to "Line clear" except by the action of the solenoids, which first unlock, then pull the semaphore arm over, and automatically lock it in that position; the reverse, of course, holds good. The contacts for working these signals are fixed alongside the trolley wires, either by means of a special ear or a bracket clamped to the bracket arm. They consist of a short length of flat brass bar, which is insulated from the ear or bracket, and is so adjusted with respect to the trolley wire that the trolley head must rub along it when passing, and so make contact between the two. The brass bar is held in position by means of springs, so that the act of making contact does not put any appreciable strain on the trolley head or wire. As the contacts are made of short length for convenience and the sake of appearances, it was considered advisable to provide some means for ensuring the signals

Digitized by Google

being pulled home and locked irrespective of the speed of the cars. This is accomplished by means of relay switches, which are closed by the action of a trolley head touching a contact, and which maintain the circuit between the solenoids and trolley wire after the trolley head has left the contact. These switches can only be opened by the semaphore arm being pulled home and locked, either to "Danger" or to "Line clear," so that the full movement must be completed with equal certainty whatever the speed of the car.

Fig. 1 shows the signal fitted to a side pole, and is taken from a photo of one which has been in use for some 12 months past. Fig. 2 is a diagram showing a section of single track and passing places fitted with a pair of signals and six contacts, which allow the following results—viz.: Suppose a car running from left to right on the diagram. As soon as the trolley head touches contact No. 1, signal B will go to "Danger" or "Line blocked." At contact No. 2 signal A will go to "Danger," thus giving the car a free run through the signal section by first blocking both ends; at contact No. 3 both signals will go to "Line clear," which opens the section for the next car or for a car going in the opposite direction. By means of contacts Nos. 4, 5, and 6 cars running from right to left carry out the same combination. As it is just within the bounds of possibility that two cars coming from opposite directions may touch contacts No. 1 and 4 at the same instant, each driver would then see his home signal go to "Danger" before he reached the home danger contact, and would thus know that there was a car at the other end of the section, in which case one car must be given the preference and allowed to go through the single track. Assume this to be the car running from right to left in the diagram, then the car running from left to right would have to back past contact No. 1, so that on entering the signal section after it was cleared, it would again set signal B to "Danger," then signal A to "Danger," and would clear both signals in the usual manner at contact No. 3. The above could also be met by fixing a second distant danger contact for signal B alongside contact No. 2. In this case the car running from left to right would not need to back past contact No. 1, but would reset signal B to "Danger" when passing this extra contact, and so block the far end of the single section. These signals are fitted with red and green bullseye lights, which make them equally efficient at night or in foggy weather. The bullseyes are so arranged that when the semaphore arm is at "Danger" it covers up the green light and exposes the red light, and *vice versâ*. The lamps for these lights are, as is the whole of the mechanism, run direct at the trolley wire voltage, and so the use of batteries, either primary or secondary is obviated. The signal lamps are, of course, fitted with a switch for extinguishing them in the daytime, the same being in a watertight cast-iron box with lock and key. This system, as far as we can see, is a simple, efficient, and thoroughly practical solution of the difficulties met with in single-track tramways and light railways. It is absolutely automatic, and permits of the track being used to its fullest extent. The possible combinations of signals and contacts are numerous, and permit of their being used with equal success for right-angle crossings, sharp curves, etc., on double or single tracks.

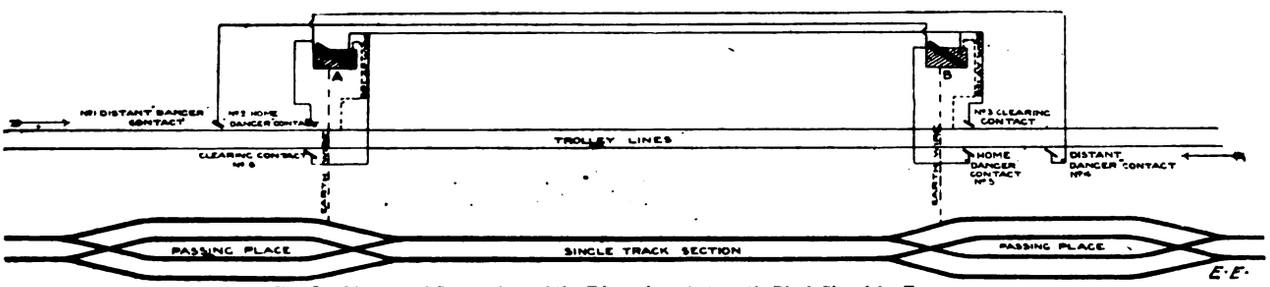

FIG. 2.—Diagram of Connections of the Edmondson Automatic Block Signal for Tramways.

SOCIETY OF ARTS.—With the approval of H.R.H. the Prince of Wales, president of the above society, the Albert medal for the year has been awarded to Prof. Alexander Graham Bell "for his invention of the telephone."

THE ELECTROLYSIS OF GAS-MAINS.*

BY JAMES SWINBURNE, M.I.C.E.

(Concluded from page 849.)

We may now consider the electrical connections of a tramway system. In its simplest form a tramway system consists of an electrical generator driven by power at the station. This is connected with an overhead wire, which is thus kept at an electrical pressure of 500 volts. Each car has a sort of fishing rod with a little trolley wheel, which makes contact with the overhead wire and connects to the motors. From the motors the circuit is led to the wheels, and thence to the rail. It is carried back to the station by the rails.

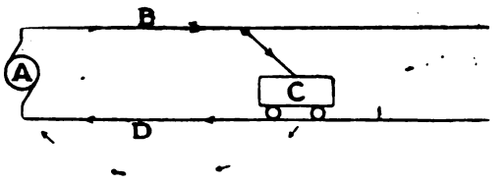

FIG. 1.

The current that goes back to the generator is necessarily equal to the current that goes out. Electricity is not like gas; there is the return circuit which must carry the whole current. Any current that leaks away from the rails must either find its way back into the rails or otherwise get back to the generator.

Whether the current will all go back by the rails, or will partly go by the earth, depends upon the resistance of the paths. Iron as a substance has very little resistance compared with damp earth; but, on the other hand, the damp earth forms a very broad path—in other words, the cross-section is very large. Again, the rails are not continuous, and the joints have more resistance than the rails. The result is that there is considerable straying from the rails. This is shown diagrammatically in Fig. 1. Here A is the generator; B is the overhead system at 500 volts; C is a car; and D is the return circuit. Some electricity leaves the rails, and returns towards the generator by the earth, and when it gets near the station it enters the rails again. The earth acts as a by-pass. Electricians talk of leakage; but the analogy is the by-pass. In Fig. 2 is another elementary system with gas-pipes shown close to the rails. The gas-pipes are generally good conductors. Sometimes the joints do not make good electrical contact, and the resistance of the joints is high. In Fig. 2 the gas-pipe is shown as E. There is a current into the pipes at F, and out again at G. As has already been explained, the earth acts as a sort of by-pass to D, and takes a share of the return current. The gas-pipe acts as a sort of second by-pass—that is to say, a by-pass to a by-pass; and there is thus a small current in the pipe. If the system is examined it is seen that the rails have a fairly large current leaving them. The rails must be proportionately corroded at these regions. Then a portion of the leakage goes into the gas-pipe at F. This does no harm, as the pipes are

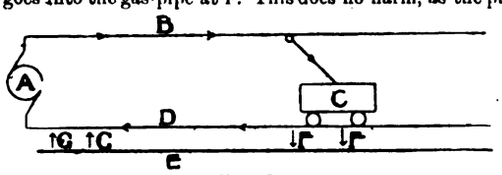

FIG. 2.

cathode there. That is to say, the current into the metallic conductor does not corrode it. At G, however, the current leaves the pipe; so there is corrosion there. The electricity that leaves the pipe at G crosses through the earth to the rail, and thus to the generator. If, therefore, the pipe is connected by means of a wire to the return or negative end of the generator circuit, the electricity leaves the pipe by a metallic conductor, so that there is no corrosion. As will be seen presently, making metallic connection to the pipes in the neighbourhood of the station is one of the methods of minimising the electrolytic corrosion.

We have mentioned electrical current and electrical pressure, and referred to resistance and conductors. It would be no use to try and give a clear explanation of what controls electric currents here, for time is too short. Many, probably most, of my readers also understand the matter already. But it may be advisable to give those who have not studied electricity at least some idea of the relations of the electrical quantities we have to deal with most. The electrical current

* Lecture delivered before the Incorporated Gas Institute.

Digitized by Google

(amperes) is analogous to a current of water, a conductor corresponding roughly to a pipe. The resistance of the conductor (ohms) then corresponds with the friction of the pipe, due to its smallness of bore or internal roughness, and the electrical pressure (volts) to the pressure or head of water. But there is this difference: the relation between the flow of water and the pressure causing the flow in a pipe is complicated; but in electricity it is very simple. The current (in amperes) is proportional to the pressure (in volts) divided by the resistance (in ohms). In the case of electrolysis there is often a back pressure; for instance, when water is electrolysed into oxygen and hydrogen. But in the sort of electrolysis which we are discussing, there is generally no appreciable back pressure. This is mentioned because it is sometimes said that electrolysis cannot take place unless there is over a volt of pressure available.

If we consider a track where the rails form the only return, if the current to be returned is large and the distance long, so that the resistance is considerable, we might have considerable pressure between the far end of the rails and the station. In America, especially in the early days, they had very high pressures on the rails—sometimes 30 volts and upwards. Taking the earth itself generally as being at zero pressure, or, to use the water analogy, at zero level or head, we may consider that one end of the rails would in the extreme case mentioned be 15 volts above the zero, and the other 15 volts below.

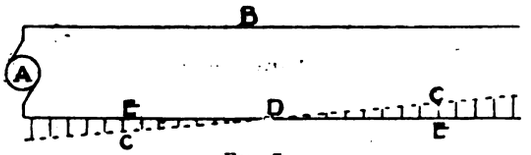

FIG. 3.

With such a pressure as this there would be considerable leakage, or by-passage of current through the earth. Any pipes lying along the route would then pick up a portion of the stray current, and suffer corrosion where the electricity left it. The variation of potential along the earthed return, supposing it to be uniform, is shown in Fig. 3. Here E E is the return, and its potential with regard to the earth is given by the vertical distance between E E and the inclined line, C C. At the far end the rails are positive (this being shown by C being above E), and no corrosion of pipes will take place; but at the near end they are negative. Between these two areas there is a spot, D, where the rails are at earth potential; and there is no tendency for electricity to pass to or from the pipes.

We may now consider the precautions and measures taken to minimise corrosion of pipes. The first thing is to keep the resistance of the return rails as low as possible. The resistance is chiefly at the joints, and it is difficult to make good contact by means of the fish-plates. The rails are, therefore, "bonded," or electrically joined by bonds of flexible copper. Sometimes to make better joints the rails are electrically welded, or welded and cast by Goldschmidt's process, or joined by pouring fused iron round them from a portable cupola. In a long line, or where the traffic, and, therefore, the return current, is large, no amount of bonding will do. The Board of Trade here come in with a regulation that a tramway must not spend more than seven volts on its return rails. What are called "suckers" are, therefore, introduced. Fig. 4 shows the system with suckers. The suckers are insulated conductors which draw off from various points of the system. They generally have what are called "negative boosters" in their circuits. A "booster" is a machine for adding a little pressure to a circuit; a negative booster subtracts pressure or sucks. It is an electric motor, driving a generator, the generator being so arranged that it sucks in proportion to the current, so that the far end of the sucker, where it joins the rails, is kept at nearly zero pressure, or not

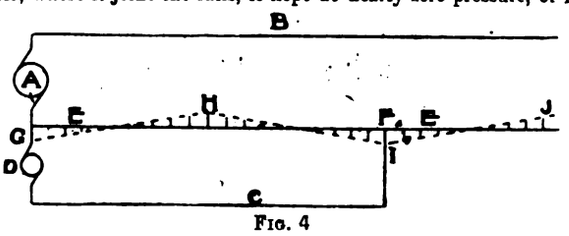

FIG. 4

more than 3½ volts below it. Thus, in Fig. 4, an insulated conductor, C, is taken from the point, F, of the rails through a negative booster, D, to the generating station. The potential of the rails is represented by the line, G H I J, which shows that some sections of the track are positive and some negative. The rails are insulated to some extent incidentally by being embedded in concrete, which is a very bad conductor when dry, but according to many measurements conducts well when wet. It might be worth while to saturate it with some waxy, tarry, or greasy material when dry. Tarring the rails, or coating them, does not insulate them permanently. A layer of asphalt keeps the ground under it dry and increases the resistance.

The Board of Trade regulations do more than limit the difference between different parts of the earthed system. They provide that, with earth-plates at the station at least 20 yards apart, with not more than an ohm resistance to earth in parallel, these plates shall only collect two amperes per mile of tramway, or 5 per cent. of the total current. Any rails must not be more than 4½ volts above any neighbouring pipes or 1½ below them. These pressures are determined with Leclanché cells. They make various other minor regulations. Sometimes, instead of using suckers, the flow of electricity is helped along the rails, as it were, by what we may call "helpers" or "helpers home." These are "boosters" arranged in the rail circuits so as to help the flow, as it were. Thus, suppose the engineer decided to keep within a limit of four volts maximum difference of pressure in his rails. At maximum load a length of rails might have four volts drop of pressure, from + 2 to − 2 volts, the middle being at the zero or earth pressure. At the − 2 point, the rail would be severed and the electric circuit led through a conductor to a booster, which would add four volts and return it to the next section at + 2 volts. The system is shown in Fig. 5, in which C and D are the boosters inserted in the rail circuit, E. The potential of each of the sections varies from positive to negative, as shown by the inclined lines, F G, I J, and K L. Helpers are not used, as far as I know; but the idea, though old, has been recently revived. Little or nothing more can be done to protect the pipes by dealing with the return-rail track. Something can, however, be done to the pipes. As has been explained, it is not the entry of the electricity into the pipes that does the harm; it is where the electricity leaves the metal and goes into the damp earth—that is to say, where the pipe is acting as anode. If all the parts of the pipe that might act as anode are connected by wires to the rails, or to the station, so that the electricity can be carried off without passing into an electrolyte, there is no electrolysis, and the pipes are safe. The region round the station is clearly that where the pipes may be anodes. This region is, therefore, often known as the "danger area," and if metallic connection is made from the negative terminal of the station to the pipes in the danger area the pipes are safe. This increases the current in the pipes, but that does not matter to the pipes unless there are joints which cause the electricity to pass round by the earth. The increase of current means increase of corrosion of the tramrails, but that is the tramway people's look out. When suckers are used they are arranged so that they reduce the pressure of the rails where they join below the earth, so that the rails are then negative to the earth. They therefore make local danger areas. The pipes should thus where possible be connected to the rails there.

We have now mentioned practically all the methods known of keeping down the chances of electrolysis by designing the tramway to produce as little effect as possible. We have, of course, only dealt with the overhead single trolley system, which is universally used in this country. One cure is to depart from the system altogether. For instance, we might have both conductors overhead. This would get rid of electrolysis altogether; but the method is so inconvenient, so costly, and so unsightly, that it is almost out of the question. Unless there were much stronger evidences of real damage from electrolysis than any we have so far, Parliament would never put such a thing on

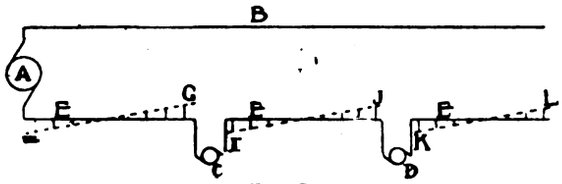

FIG. 5.

tramway companies. The double trolley has been used in one or two places, but the results are not encouraging. Some of the conduit or culvert systems, in which the electric conductors are in a sort of long nearly closed conduit, with a narrow slit along the top, have both conductors insulated; but this give rise to difficulties at crossings and turn-outs. Surface-contact systems can also be designed to have no earthed conductors, but in their case also it is very much more difficult to insulate both conductors. The precautions in design and working which can be taken by the tramway engineers are thus: (*a*) good bonding of rails, and rails of large section; (*b*) suckers to the rails from the power-houses; (*c*) insulation of rails by concrete, and so on; (*d*) inserting "helpers" in the rail circuits.

There is still another system which has not received the attention at the hands of electrical engineers that I would suggest it deserves—that is, the "three-wire" system. Along one line the overhead wire is at a pressure of 500 volts; along the other it is negative, at − 500 volts. The circuit is then not from the rails to the power-house, but merely across to the other rails and home by the next tramcar and the − 500-volt overhead wires. The system is more complicated, and there are 1,000 volts between neighbouring overhead wires, as well as the usual 500 between one and the earth. There is also difficulty in balancing, so that there is approximately the same current on each side. Connections from the rails to the power-house are still necessary, but they are smaller and much less numerous for a given area.

We may now consider what the gas and water companies can do to protect their pipes. Throughout the danger area they should be metallically connected with the power-house or the suckers. Coating with Angus Smith's composition, or asphalt, tar, and the like, prove to give little or no protection. It is found that wrought-iron pipes are corroded more quickly than cast, especially close-grained cast iron. In this country wrought iron is only used for service pipes, as far as I know. It would be an advantage to destroy the electrical continuity of pipes by occasionally packing joints with sulphur, sulphide of iron, or something other than lead. Lead does not make a good electrical joint. Pouring lead round does not remove the bituminous coating of the pipes. Lead also soon coats itself with insulating compounds, such as hydrated oxide, which prevents its making good electrical contact. This should be done, especially in places where the ground happens to be dry and well drained. It has been proposed to adopt earthenware or stoneware pipes. Such schemes are of little value. The pipes are already down, and, generally speaking, will remain down unless something serious happens to them. The insulation of occasional joints in water-pipes would also be of advantage. It might be supposed that this would do little, because the water conducts, and would therefore make a passage round the insulated joint. The water supplied to houses is, however, such a

Digitized by Google

very poor conductor that the current carried by it may be neglected. Insulating the joints in this way may, however, sometimes do harm. For instance, suppose a line of pipe is carrying a current which is taken to the power-house by a metallic wire connected to it for that purpose, the pipe might have no current leaving it and therefore no corrosion. If the pipe is insulated at a joint it will introduce a local resistance, and the electricity will leave the pipe and go into the earth close to the joint, entering the pipe again a little further on. One side of the joint thus become anode with corrosion, while the other becomes cathode, which does not matter. Insulating joints does not, therefore, necessarily help. It reduces the current, but at the expense of local corrosion, unless the joint is in very dry ground. If joints are insulated at very frequent intervals, the pipe will be so discontinuous as a conductor that it will pick up no appreciable current. Insulation of joints is, therefore, a good measure when taken judiciously, but it is not always possible, as a company cannot well open up the roads on purpose to break the joints and recaulk the mains. In America it has been proposed to make gas and water pipes of stoneware Such pipes could, of course, be made, and in some ways it might be easier to render them gastight. They might also be made strong enough to stand a steam-roller without being buried very deep. But any change of that sort cannot be considered seriously in this country, except for new mains. Practically the only thing the pipe-owning companies can do to safeguard themselves, or to lessen the effects of stray currents, is to insert insulating joints at intervals where possible, and to connect the pipes metallically with the power-house, or the rails in danger areas—that is to say, in areas where the pipes are apt to be anodes. Cast-iron pipes are sometimes joined up with wrought-iron or lead service pipes, often with brass couplings. Such metals in damp soil set up local currents of their own, which eat the lead or wrought iron apart altogether from any tramways.

The next, and perhaps the most important, question is: How much damage are electrical tramway systems doing now, and how much will they do in the future? We hear a great deal about the damage done in the United States, and there is no doubt that there has been a great deal of trouble there. The statements in the technical Press are exceedingly difficult to deal with. There is strong partisanship and great exaggeration. In addition, many of those dealing with the matter have very inaccurate notions about electrolysis. The conditions in America are different, but especially they have been different. Damage by electrolysis is essentially a matter of time, and the corrosions that are now making themselves evident in America are the results of past working. Electrical tramways have been in extensive use there for some 12 years: and it might appear that the present state of the pipes show us what to expect here in 10 years or so. This, however, is not so. In America, especially in the early days of tramways, the rails were of small section; and they were very badly bonded. They were largely laid in mud which forms the bed of many American roads. But, more than all this, they frequently allowed 30 volts in the rails, or three times our permissible maximum.

We have developed electrical tramways slowly in this country. One result of our British way of doing things is that we now put our tramways down well. The Board of Trade also limit the pressure allowed between points in the rails; and the tramway engineers generally keep very much within this limit for their own sakes. It must be remembered that the tramway people do not want to eat pipes. They may be made liable for damages some day or other if they do. But there is another point. Any stray electricity that gets into pipes must have left the rails, and must have corroded them proportionately. But the current in the pipes is only a fraction, generally a very small fraction, of the whole stray current; so that if there is corrosion of pipes, there is a very much greater corresponding corrosion of the tramway rails. In their own interests, therefore, electrical engineers keep the stray currents down as low as they possibly can. Of course, if a considerable part of the stray current goes along a pipe, and frequently leaves it to go round an insulated joint, returning to it after the joint, there is corrosion wherever it leaves the metal. If there are many such joints, the total corrosion of the pipes may be comparable with that of the rails, or even greater, though the current from the rails is greater than that in the pipes. But the frequency of such insulated joints in practice sends the resistance up, so that there is then comparatively little current in the pipe circuit.

The most remarkable fact about electrolytic corrosion is that it is clearly not so great as might be expected. It has even been said that earth conducts like metals, non-electrolytically, so that electricity can leave rails or pipes and go into the earth without the corresponding corrosion. This theory is far too good to be true. The components of the soil are mostly insulators in themselves. Such substances as silica (sand), and the various silicates of which clays are composed, and chalk, are all insulators; and the conduction is due, not to them, but to the salts dissolved in the water that moistens them. No transparent body can conduct otherwise than electrolytically. This theory appears to me, for one, quite untenable. It is much more probable that, in estimating the corrosion of pipes, people are apt to overestimate the difference of electrical pressure between points in the earth. Take a simple case of a long straight single rail on the surface of comparatively badly conducting earth. Suppose it is at two volts above the ground in pressure. The ground just in contact with the rail will be raised to two volts. The earth a long way from it, on the other hand, will be at zero pressure, if not disturbed by some other source of electrical pressure. There is thus a gradual fall of from two volts to zero as the distance from the rail increases. But the rate of decrease of pressure is much greater close to the rail than far off it—in fact, the rate at which the pressure decreases is approximately inversely proportional to the distance. The result of this is that the pressure falls quickly as the distance from the rail increases. Another way of putting it is that the earth itself in the immediate neighbourhood of the rail acts as a sort of coating, the two volts being nearly all spent on it. The pressure of the earth a short distance from the rail will thus be very little above zero. If a good conductor, such as a pipe with electrically conducting joints, were laid in earth which was two volts above zero pressure, and if the pipe were kept at zero pressure by being connected to a power-house, or by going into a region where the earth was at, say, two volts, it would, if of equivalent size and shape, pick up a current equal to that leaked by the rail already discussed; but if it is laid in a region at a minute fraction of a volt above the normal, it will only pick up a corresponding current. One of the few papers which gives definite information in a useful form is by Larsen and Faber. These observers measured the currents in pipes following the tracks, and found values which are serious. These observations go to show that pipes close to lines with large pressure drops will, if not protected by metallic connections, be seriously corroded in course of time. It is probable, in spite of this special case, that pipes pick up much more minute currents than is generally believed. Another reason for supposing that the pipes do not take up very large currents is that there are earth currents due to natural causes. Now, earth currents would cause electrolysis just as much as stray tramway currents; but pipes have been in the ground for not very far off a century, and pipes 50 years old are often found to be as good as new. Yet the earth currents have been going on all the time. Unfortunately, we have few useful data about earth currents. What we want to know is the differences of electrical pressure between one region and another. The observations are made by the telegraph authorities, and they have nearly always given their results in terms of the current in their wires. They have given these without stating their resistances, so that their figures are useless. A book by an eminent German professor has recently been published furnishing figures involving an enormous amount of work. They deal with Germany, but convey no information, because the data which would make them valuable have been inadvertently dropped out.

Fortunately a few telegraphists, instead of reading the deflections of a galvanometer, have tried how many telegraph battery cells had to be put in to reverse the current, and from this we can get a rough idea of the differences of pressure between different regions. I may mention that Varley once found between London and Ipswich a difference of pressure of about 140 volts, or 2½ volts fall of pressure per mile. Such pressures are variable, but they are comporable with the disturbances due to electrical tramways. I have measured the currents in pipes where there are no tramways within many miles, and found them comparable with those found near working tramways. Yet they do not seem to do so very much harm. It is possible that all corrosion of pipes, apart altogether from tramways, is produced by or accompanied by electrolysis. Dissolved oxygen, or oxidising solutions in the earth, would attack iron without electrolysis; but it is doubtful if the moisture in the earth contains such matters. The decaying vegetable matter and humus, and in towns decaying animal matter, would all be reducing agents, and prevent any direct oxidation of iron. Though what I have been saying may tend to allay fears as to the ravages of electrolysis, I certainly do not mean to say tramways will do pipes no harm. They certainly will do them no good. The question is: How much harm will they do? Electrolysis involves damage of the most insidious kind. It means a gradual corrosion of pipes until they either break or develop leaks in all sorts of unexpected places. Whether it will really damage the property of gas companies to a serious extent I for one cannot say. It is a matter of time. The best thing gas and water companies can do is to watch their pipes carefully, inspecting them whenever they are open for other purposes. When the road is opened and a pipe uncovered, it would be as well to measure the electrical current in it. It is quite easy to measure the current in a pipe. The fall of pressure over a given length, excluding any joints, can be taken with a sensitive galvanometer. The resistance can be calculated or got by measuring a similar pipe. From these data the current is got. By including a joint the resistance of the joint can be found. The measurements of current should be taken day and night, to see if the current is due to tramways. Another measurement that is important is the relative pressure of the pipe and neighbouring earth. If the pipe is positive to the neighbouring earth, it is acting as an anode, and is therefore being corroded, and ought to be metallically connected with the power-house. If the pipe companies cannot get legal protection, the best thing they can do is to make friends with the tramway people. Where the electrical tramways and the gas and water are owned by a local authority, there ought to be no difficulty, but even otherwise the electrical company and the pipeowners would do well to work together. To make these electrical tests involves some electrical knowledge, and gas and water companies do not want to employ electricians on their staffs. The tramway people could generally make these tests for them without any great difficulty, and arrange experiments with them.

As to what the right course for Parliament to take may be, there is much to say on both sides. On one side it would not do to veto earthed returns, because this would throttle an industry. It is quite certain it would injure the tramway industry enormously to forbid earth returns. This means depriving the public of means of locomotion; and depriving the tramway shareholders of profits. The tramway shareholders are part of the public, and have a right to be considered. So are the gas and water companies, and their shareholders. In addition, they were there first. But the evil of vetoing earthed returns is serious and certain, while the evils of electrolysis are comparatively remote, and uncertain; so taking industry broadly, Parliament has so far decided to allow earthed returns.

The next question is as to whether pipe companies should have damages if their pipes are eaten. This seems obviously fair. But there is very serious difficulty in carrying such protection clauses into effect. A gas company find their pipes eaten in one district. The first thing is to prove the corrosion is electrolytic, and not due to natural causes. This is in itself not necessarily easy. Suppose it is clear that the failure is due to electrolysis, the electrolysis may be

Digitized by Google

due to natural earth currents. If not, and it is due to an electrical system, who is to say which system? In small towns where there is only one tramway system the chance of appreciable electrolysis is small. In large towns there are, or soon will be, several tramway systems, and probably some electrical railways. It would be very difficult for a London company to decide who ate their pipes, and still more difficult to bring the crime home by the clumsy and expensive method of arbitration. To make the tramway people liable for any damages is obviously fair; the real difficulty is to carry the matter out. Such a liability is for that reason very serious to the tramway. A small tramway—which we will for this example suppose really innocent—is liable to be mulcted in damages that might ruin it by a mistake of judgment of an arbitrator, or of experts called before him. This is a very serious liability.

To sum up there is electrolysis, and your pipes are being eaten, but whether the corrosion is really serious or not can hardly be settled yet. Tramways are increasing in all directions, but they are also being more and more carefully designed. The large systems use lead-covered cables themselves, which are infinitely more easily damaged by electrolysis than gas-pipes, because the lead is easily corroded, the conductors are continuous, and the cables are generally near the tramlines. The electrical tramways are thus more likely to damage themselves than their neighbours by any bad design or careless working. It behoves gas and water companies, however, to watch carefully. The question of electrolysis is not really settled. In the course of years we may have more information, and we may then find either that the stray currents are practically harmless, or that new laws have to be made.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

493. Since the speed of an induction motor depends upon the periodicity and the number of poles, what advantage is obtained by increasing the field flux?—M.

N.B.—Will "M." kindly send his name and address?

494. What are the benefits of carbon breaks on switchgear? Is the resistance of the carbon of any practical value? What principles should guide one in designing such "breaks," and how would you determine the necessary size of carbons for breaking a given load?—L. W. G.

ANSWERS.

Question No. 487.—Give details of the best method of regulating the direct-current E.M.F. of a rotary converter.

Best Answer to No. 487 (*awarded* 10*s.*).—All the methods of regulating the continuous-current E.M.F. in common use involve the regulation of the alternating E.M.F. supplied to the slip rings, and only differ in regard to the way in which this is done. If the load on the machine is fairly steady, as in lighting work, hand adjustment of the alternating voltage is sufficient and is generally preferred, whilst if the load is subject to large and sudden variations, as in the case of traction work, hand regulation is not effective, and automatic regulation must be resorted to.

Hand regulation can be carried on in any of the following ways: (1) By inserting resistance in each phase as the load is reduced. This, though perhaps the simplest, is very uneconomical, and is practically never used. (2) By inserting an adjustable choking coil in each phase and increasing the volts choked as the load is reduced. This method is simple and cheap, and the only objection to it is the lowering of the power factor of the supply system. (3) The number of turns in the primary or secondary of the transformers supplying the converter can be altered by means of a special switch, and the ratio of transformation thus altered. The objection to this is principally one of price, as well as the somewhat special winding of the transformers. (4) Another plan, sometimes employed by the Allgemeine Elektricitäts-Gesellschaft, consists in mounting a small alternator on the same spindle as the rotary converter and connecting its armature windings in series with those of the converter. The alternator then acts as a booster, and, by adjusting and reversing its field excitation, the number of volts which it adds to or subtracts from the supply mains can be varied at will. The same result can, of course, be obtained by a booster on the continuous-current side. There is no special advantage in this method except, perhaps, when dealing with heavy currents, and it is expensive. (5) Probably the best method of hand regulation, and that most commonly employed, consists in inserting a small static boosting transformer with adjustable voltage in each phase. Such transformers are made in various forms, one of the best known of which is shown in Fig. 1. The central moving core, A, carries a primary winding connected across one phase of the supply mains. The external stationary core, B, is wound with two secondary coils connected in series with the same phase. The central core can be turned through an angle of 180deg. When it is vertical, the secondary voltage is a maximum. As it is turned round, the secondary voltage gradually falls and become zero when A is horizontal, the fluxes through the different parts of the secondary neutralising one another. If A is turned still further, the secondary voltage rises again, but is now in the opposite direction relatively to the supply voltage.

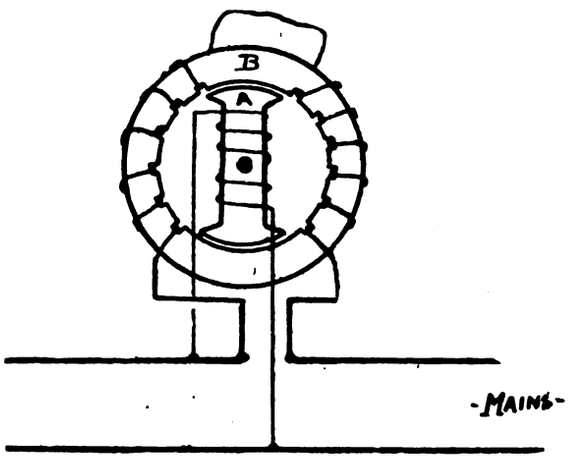

FIG. 1.

The maximum booster secondary voltage, stated as a percentage of the supply voltage per phase, need, therefore, only be half as much as the percentage change in continuous-current voltage required. The alternating supply voltage is given such a value that the correct continuous-current voltage is obtained at about half-load with the booster giving no volts. Then, as the load increases or falls off, the core A is turned one way or the other so as either to add or subtract volts. In the case of polyphase rotary converters, as many boosters as phases are required, and their handles should be interlocked so that all the phases are adjusted at the same time and equally.

Turning next to the question of automatic adjustment of the voltage, this has been largely employed in traction work, and is always attained in the same way—viz., by compound winding the field of the rotary converter and inserting a certain amount of self-induction in the alternate-current supply mains. The action depends on the fact that the phase relation of the alternating current flowing into a rotary converter to the voltage at its terminals depends on the excitation of the machine. For every load there is a particular value of the exciting current which makes the power factor unity—the current being in phase with the voltage—and if the excitation is less than this value, the supply current lags behind the voltage, and the power factor is less than unity; whilst if the excitation is greater, the supply current will be ahead of the voltage in phase, as in the case of a condenser, and the power factor will again be less than unity. The effect of this on any self-induction in the circuit is to cause

Digitized by Google

the voltage across the self-induction (which always lags nearly 90deg. behind the current) to vary in phase relatively to the supply voltage, and consequently to vary the actual voltage supplied to the slip rings of the converter. This is shown in Figs. 2, 3, and 4. Fig. 2 represents the case when the current, A C, is in phase with the slip-ring voltage, A E, and the choking-coil voltage, E S, is practically at right angles to both. In this case the external supply voltage, A S, is greater than the slip-ring voltage, A E. When the current, A C, lags behind the voltage A E, as in Fig. 3, the difference between A S and A E becomes still greater; whilst if the current is ahead of the voltage (Fig. 4) the slip ring voltage, A E, is seen to be actually greater than the external voltage, A S—the choking coil adding some volts on, in fact. By so proportioning the shunt and series windings of the converter that at light loads the input current lags, whilst at full load it leads, and by adjusting the choking coils inserted in the mains by experiment, it is possible to produce either a continuous-current voltage which is constant at all loads, or one which actually rises 5 or 10 per cent.

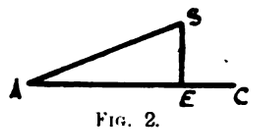

Fig. 2.

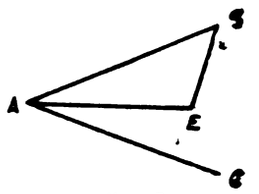

Fig. 3.

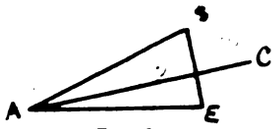

Fig. 4.

from no load to full load as desired. Instead of employing separate choking coils, it is sometimes preferable to arrange the supply transformers to have considerable magnetic leakage, and so act like choking coils.—Q.

Answer to No. 487 (*awarded* 7*s.* 6*d.*).—There are two good methods of regulating the direct-current pressure of rotary converters. For lighting work, where fine regulation is required, the best results are obtained by using an inductor regulator or some modification of the inductor regulator. For traction the best regulation is obtained by compounding. The resulting pressure on the direct-current side of a rotary converter varies as the alternating pressure on the slip rings. This is the principle upon which both the above methods of regulating depend.

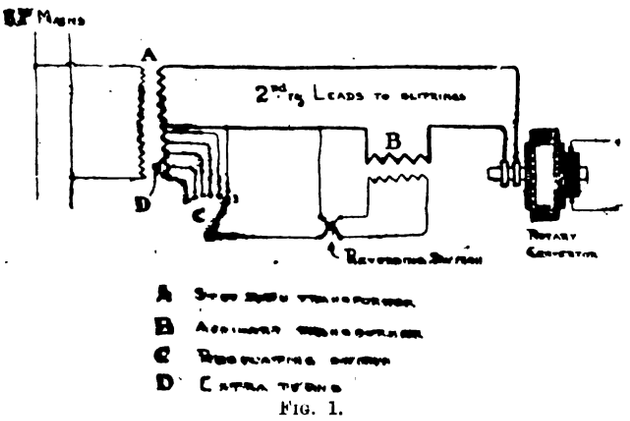

Fig. 1.

1. *Inductor Regulator.*—The inductor regulator consists of an iron core which can move inside both a shunt coil and a series coil wound on each phase of the alternating circuit. (If step-down transformers are used, of course these coils are on the secondary side.) When the iron core is moved, it alters the mutual induction between the shunt and series winding, and therefore alters the pressure on the slip rings. If the core is pulled out of the coils the mutual induction between them is reduced, the pressure on the slip rings becomes greater, and therefore the pressure on the direct-current side rises. On the other hand, if the core is moved further into the coils, the mutual induction is increased, the pressure on the slip rings becomes less, and consequently the direct-current pressure less.

2. *Modification of the Inductor Regulator.*—This is shown in Fig. 1. A few extra turns, D, are added to the secondary of the step-down transformer, A. These extra turns (which can carry about one-fourth of the full secondary current) are connected, as shown, through a regulating switch, C, to the primary of the small auxiliary transformer, B, the secondary of which is in series with the low-pressure alternating circuit. As the regulating switch, C, is turned from left to right the pressure in the primary of B is increased, and a proportional E.M.F. is induced in the secondary. This induced E.M.F. is added or subtracted to the pressure on the slip rings, according to the position of reversing switch. The method of working this regulator is quite simple. With the reversing switch in one position, as the regulating switch, C, is turned from left to right, the direct-current pressure will drop. With the reversing switch changed over, when C is turned as before, the direct-current pressure will rise. Of course, the reversing switch must only be thrown over when all the extra turns of D are cut out—*i.e.*, when the arm, C, is on contact.

3. *Compounding.*—As a rotary converter is a synchronous machine, the power factor it runs at depends upon the strength of the field. At a certain excitation (as shown by its V curve) the power factor is a maximum. If the excitation rises above this point, a leading alternating current is obtained, and the pressure on the slip ring is increased. On the other hand, if the excitation falls below this point a lagging current is obtained, and the pressure on the slip rings is decreased. By arranging the shunt field winding, and, if required, putting choking coils in the alternating circuit, the compounded rotary converter when running at no load takes a lagging current. As the load increases, the compound winding increases the field, diminishes the lag of the current, and thus increases the pressure on the slip rings, producing a proportional rise in the direct-current pressure. When the machine is fully loaded the alternating current will be leading, and the direct-current pressure will have increased in proportion to the increased pressure on the slippings. By suitably adjusting the compound winding and the choking coils, a very good automatic regulation of the direct-current pressure is obtained. The compound winding may be used as well as the inductor regulator on the same machine. This is a great advantage when the machine supplies both a lighting and a motor load.—R. W. Gregory.

Answer to No. 487 (*awarded* 5*s.*).—The difficulty in regulating the direct-current E.M.F. of a rotary converter arises from the fact that the ratio of the direct to the alternating applied E.M.F. is constant, and cannot be altered by varying the excitation of the machine. Hence the only way of regulating the direct-current E.M.F. is to vary the applied alternating potential difference. The best method of doing this is to wind the field-magnet circuit of the rotary as a compound machine, and to place three choking coils in series with the three slip rings on the three-phase side. When no load is taken from the direct-current side the rotary is under-excited, and the current in each phase lags considerably behind the E.M.F. in that phase. Suppose E is the total applied E.M.F. in each phase, then if e_1 be the potential difference across the choking coil, and e the potential difference between the slip ring and the neutral point, then at no load E is approximately equal to $e_1 + e$, because e_1 and e are nearly in phase. As the load on the direct-current side increases, the excitation increases owing to the series windings of the field magnets, hence e gets more and more into phase with the current, and at full load is generally in advance of the phase of the current. When e is in phase with the current,

$$e = \sqrt{E^2 - e_1^2},$$

and it is easy to show by geometry that this is always greater than $E - e$, and ultimately, if e were 90deg. in advance of the phase of the current,

$$e = E + e_1.$$

It will be seen that e continually increases as the excitation of the machine increases, and hence a considerable amount of regulation can be obtained

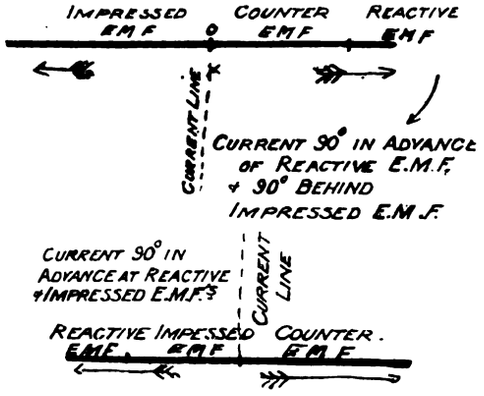
Mr. Eborall, in the *Journal* of the Institution of Electrical Engineers, vol. xxx., p. 718, states that it is perfectly easy to arrange for the direct-current pressure to be over-compounded 10 to 15 per cent., the actual regulation being nearly as good as with an ordinary over-compounded direct-current machine. To obtain this amount of regulation, the drop across the choking coils at no load must be 10 per cent. of the applied alternating potential difference, and the over-compounding of the field magnets of the rotary must be about 10 per cent. greater than what it would have been on the equivalent direct-current machine, for the direct-current pressure is not proportional to the field flux, but to the impressed alternating-current pressure on the slip rings.—J. C. R.

Answer to No. 487 (*awarded* 5*s.*).—The commercial methods of regulating the continuous-current voltage of a rotary converter depends upon whether the machine is being used for traction or lighting. We will consider the traction regulation first. We must remember (*a*) that a rotary converter simply consists of an ordinary dynamo or motor, with an ordinary distributed continuous-current armature winding, with a commutator at one end of the shaft and slip rings at the other, connected, in three-phase working, to points 120deg. apart on armature winding, alternating current being led into the machine at the slip rings and taken out at the commutator end as continuous current, consequently it can easily be seen that the continuous-current voltage depends upon the voltage impressed upon the slip rings; (*b*) also that the converter runs in synchronism with the main generator, and, in fact, behaves very much like any ordinary synchronous motor. In any converter we have to consider three separate E.M.F.'s set up: (1) impressed E.M.F, depending upon generator volts; (2) counter E.M.F., depending upon excitation and field of machine; (3) reactive E.M.F., due to current passing through reactance and resistance of armature, and which is proportional to that current.



The algebraic sum of these three E.M.F.'s is zero. Suppose the converter, running synchronously, is under-excited, then the counter E.M.F. is less than the impressed E.M.F. (to which it is always in phase and opposite). Consequently to fulfil the aforementioned condition, the reactive E.M.F. becomes in phase with and adds to the counter E.M.F., so that the algebraic sum is zero. But according the principles of alternating currents, the current in a system is 90deg. ahead of the E.M.F. of self-induction, and consequently it must be 90deg. behind the impressed E.M.F., or in a shorter expression it is "lagging." Similarly, if the machine is over-excited, so that the counter E.M.F. is greater than the impressed E.M.F., then the reactive E.M.F. becomes in phase with the impressed E.M.F., and as current is 90deg. in advance of reactive E.M.F., it is also 90deg. in advance of impressed E.M.F.; consequently the current of the system is said to be leading. It is thus seen that by suitably altering the excitation of the converter, leading or lagging currents can be induced in the system.

In tramway practice the converters are excited by a shunt winding across the continuous-current 'bus bars, and also an additional compound winding in series with the armature. It is so arranged that at no load the converter is under-excited, and the current in the transmission system is lagging. This increases the E.M.F. of self-induction of the line, and drops the voltage at the receiving end, and consequently the impressed E.M.F. on the slip rings and the continuous-current voltage usually to 500 volts. As the load increases the excitation also increases, due to the compound winding, and with it the counter F.M.F., thus bringing the impressed E.M.F. and current into phase, then the line drop is proportional to resistance only; therefore voltage at receiving end rises and also continuous-current volts. At full load the counter E.M.F. is greater than the impressed E.M.F., and consequently current leads, and voltage rises up to the usual maximum of 550.

For lighting work, converters shunt wound, the power factor of the system is usually kept at unity, to reduce distribution losses, by adjusting the field with the rheostat, and by using some form of power factor indicator. Then to vary the continuous volts, the impressed E.M.F. on the converter slip rings is reduced or increased by means of a rheostat which cuts in or out some of the windings of the transformers supplying the converter. In the first case, for traction work, the control is automatic, but in the second case, for lighting, the control has to be done by hand.—F. H.

Question No. 488.—Give a full description of the proper tests which should be applied to girder section steel tramway rails, say 100lb. per yard; also what results would be considered satisfactory from such tests.

Best Answer to No. 488 (*awarded* 10*s.*).—In the first place, the rails should correspond exactly to size as regards depth, width, and depth of groove, width of tread, etc., these being fixed beforehand in accordance with their suitability for the work in hand, and a template made for the approval of the engineer responsible before they are put in hand. For this comparatively heavy section (100lb.) they should be in lengths of 40ft or 45ft. as to at least 90 per cent., but a proportion of shorts equal to not more than 10 per cent. may be allowed, varying from 30ft. to 37ft., these shorts being cut from longer rails having faulty ends, and being used at curves, stops, etc. Each rail should be rolled from a single ingot of Bessemer steel, having the chemical proportions approximately as follows: carbon from ·45 to, say, ·55 per cent., silicon not more than ·06 per cent., sulphur not more than ·06 per cent., and phosphorus not more than ·06 per cent. The remainder to be iron and manganese, with a trace of copper. Samples should be tested from time to time by a chemist to see that these proportions are not exceeded. The ingots should be cast of such a size as to leave an over-plus at the end of each rail of about 18in. for cutting off, and all ingots should be reheated before cogging. Rails should be free from cracks, excrescences, burrs, or other defects, and of uniform section for the whole length. They should be perfectly straight and true, and their ends sawn off square. Some engineers specify that they should be machined where the fishplates go, but this is hardly necessary, although undoubtedly an advantage in getting perfect alignment when laid.

With regard to actual strength tests, as specified below, some of these appear rather severe, and any well-established English firm of railmakers may be relied upon to supply an article quite capable of meeting the demands made on the rails in practice. Test pieces should be taken from each day's make, and tested in the usual testing machines at the maker's works. The rails should show a tensile strength of from 40 to 47 tons (averaging about 45 tons) per square inch with an elongation of 15 per cent. with a contraction of area of, say, 25 per cent. and an elastic limit of 30 tons per square inch. Any rail should support a dead load of 31 tons suspended from its centre, when held on solid bearings 3ft. 6in. apart in the clear, and should not show a greater deflection than $\frac{1}{4}$in. after half-an-hour's time, or any permanent set on removal of the weight. Any rail should stand being bent cold to a radius of 30ft. It is usual to specify that if 10 per cent. of the rails fail under any of these tests, the lot taken from that blowing shall be condemned, and the rails are sometimes marked so that this can be distinguished.

The holes for the fishplates and tie-bars should be clean and free from burrs, those for the fishplates being preferably drilled, and those for the tie-bars punched at the right distances apart; a deviation of, say, $\frac{1}{16}$in. to $\frac{1}{8}$in. in position, and $\frac{1}{32}$in. to $\frac{1}{16}$in. in size being allowed.

Digitized by Google

The fishplates should be made from the same quality of steel as the rails, and the tie-bars of wrought iron, or preferably of steel with a tensile strength of 25 tons per square inch.—J. A. MORTON.

Answer to No. 488 (*awarded* 7*s.* 6*d.*).—As the track is one of the most expensive items in a tramway system, costing from £6,000 to £8,000 per mile, or from 35 to 50 per cent. of the total cost of the installation, it is well to make sure that the materials and workmanship are both as good as can be procured. If the track is bad, it at once reacts on the rolling-stock, causing the car trucks, motors, etc., to wear much faster than they otherwise would do The general adoption in this country of a "standard" rail section is much to be desired. With the present multitude of sections, which are constantly being added to, it becomes impossible for railmakers to stock rails, hence the time of delivery and also the cost of the rails is much increased. The conditions to be complied with in designing a "standard" rail section are so limited that there should be little difficulty in arriving at the best way of meeting them. The Board of Trade have recently made an announcement that the minimum weight of a rail shall be 90lb. per yard—*i.e.*, a sectional area of about nine square inches for a hard-steel rail having a conductivity of one-twelfth to one-fourteenth that of copper. The rails laid on electric tramways in this country have a life of from six to twelve years, depending on the curves, the gradients, and the traffic, etc.

During the last 20 years there has been a considerable change in the chemical composition, physical qualities, etc., of tramway rails. Ten years ago the common percentage of carbon was ·35, which was a very soft steel indeed. These were fairly successful with horse traffic with cars weighing three or four tons, but failed completely with the 10 or 12 tons cars used with electric traction. The following rail composition was stipulated for Glasgow, and represents the latest practice: carbon, ·55 to ·65 per cent.; manganese, ·8 to 1·0 per cent.; phosphorus, ·06 per cent. (but not more); sulphur, ·05 per cent. (but not more); silicon, ·15 to ·2 per cent.

As regards *tests* no definite understanding exists, though a drop test seems very general. A piece of rail 4½ft. to 5ft. in length is taken, and is rigidly supported with a clear space of 3ft. between the points of support. A weight of about 2,000lb. is then dropped vertically some 15ft. or 18ft. on to the centre of the rail, the stress being transmitted vertically through the web. The rail must not break or show signs of fracture, or unduly bend. A test of tensile stress is also very common. Mr. W. Howard Smith suggests the following in a very interesting paper published in the *Electrical Engineer*, July 19, 1901. The breaking stress per square inch in tension should be from 42 to 48 tons. The elongation over a length of 8in. should be 15 per cent. I have found from tests that the elastic limit in tension varies from 28 to 32 tons per square inch, and the breaking stress from 40 to 48. The contraction of area at the point of fracture varies from 30 to 60 per cent. A 100lb. rail would have a cross-sectional area of about 10 square inches, hence the elastic limit should be from 280 to 320 tons and the breaking load 400 to 480. The usual lengths of rails now supplied are 45ft. and 60ft. The 60ft. lengths are somewhat inconvenient, however, requiring extra long trucks on railways, and are also cumbrous to handle on the road, but they save bonds and joints, and are better than the short lengths when once they are laid.—T. SQUARE.

Answer to No. 488 (*awarded* 5*s.*).—The usual tests which girder steel tramrails are subjected to are: tensile tests, falling weight tests, and chemical tests.

The tensile test pieces are cut from the rail and prepared and broken in the usual manner which is familiar to all readers. The usual figures for such tests are: breaking stress 37 to 43 tons per square inch; elongation in length of 8in., at least 15 per cent.; contraction of sectional area, at least 30 per cent. For rails used on the Huddersfield system the figures were as follows for 98lb. rails: breaking stress, 43·81 tons per square inch; elongation, 18·1 per cent.; contraction, 47·8 per cent.

Falling Weight Tests.—A piece of rail 5ft. long on supports 3ft. apart to resist a blow from a weight of one ton, falling on the centre from a given height, without causing more than 1in. deflection; a second blow from given height without showing sign of fracture. For rails 90lb. to 100lb. weight per yard the drops would be 9ft. and 22½ft. respectively.

Chemical Tests.—The following tables give the percentage limits of foreign matter in steel allowed in usual specifications, but the maximum figures are in no case to be exceeded:

English practice.

Carbon.	Manganese.	Silicon.	Phosphorus.	Sulphur.
0·4-0·5	0·85-0·95	0·06	0·10	0·08

American practice.

0·4-0·6	0·76-0·10	0·66-0·20	0·06-0·11	0·047-0·07

Of course, the chemical composition varies slightly according to design and manufacture, but above figures are limiting proportions.

The Illinois Steel Company give the following figures and test in their standard specifications for steel rails 70lb. to 100lb. per yard: carbon, 0·45 to 0·55; sulphur, not to exceed 0·05; phosphorus, not to exceed 0·10; silicon, 0·1 to 0 2; manganese, 0·8 to 1·0. Also test during manufacture: from each heat one ingot shall be cast 2½in. by 2½in. by 6in. long, to be drawn down at one heat by hammering to a test piece ¾in. square and 18in. to 20in. long. The same when cold to be bent to a right angle without breaking; bar to be bent by blows from a hammer.—F. H.

Answer to No. 488 (*awarded* 5*s.*).—The first test to be mentioned is probably the usual and well-known tensile test. A piece of metal of the same material as the rail is obtained, either of rectangular or circular section (Fig. 1). The size of this section will, of course, depend on the capabilities of the machine which will be used for the test.

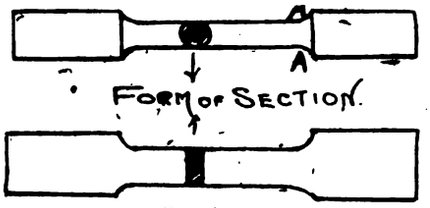


FIG. 1.

It might be mentioned that care must be taken not to make the radii at A A small. Two centre punch marks are made on the axis of this specimen 2in. apart. This is done very exactly. The specimen is now put in the machine and is loaded *gradually* until it breaks. The commercial method of measuring the extension is to press the two broken pieces together, and measure the distance apart of the centre punch marks by means of a steel rule, having on it one-hundredths of an inch, and a pair of finely pointed dividers. The extension in one-hundredths of an inch × 200 gives the elongation per cent. in 2in. According to Unwin's "Testing of Materials of Construction," 35·4 tons per square inch was an average of a certain class of rails and 29·5 per cent. was the elongation in 2in.

The next test is that for toughness. The test usually employed for this is a bending one. A 3ft. length of rail is used if required for breaking, and anything up to about 6ft. is used if a test for deflection and permanent set is required. The deflection is a measure of the toughness. Figures can hardly be given for a test of this description, as the moment of inertia of the section of the rail is one of the principal features of the test, and this differs in different sections. Unwin describes a test in the above-mentioned work which has been made with rails. He says: "To control the bending test, a falling weight test has been used. A monkey or ball, weighing 300lb., 600lb., or 1,000lb, and falling 6ft., 12ft, or more on the rail bends it more or less; the number of blows the rail will stand before twisting or breaking or deflection with one blow is taken as an index of toughness. For some usual figures of tests I would recommend "G. W." to Unwin's book, or to the *Proceedings* of the various institutions of engineers.—T. T.

THE EMBANKMENT TRAMWAYS.

The House of Lords on Monday last struck out of the Tramway Bill of the London County Council all those clauses which dealt with the construction of tramways south of the Strand. This leaves the shallow tunnel line down the new street now under construction, but it will have no outlet on the Embankment nor any connection with another tramway line at its southern end. The reasons given in the debate for the rejection of the proposal to construct tramways on the Embankment were many, but we believe that the consideration of supreme importance in the ballot was the knowledge that the Bill under consideration was only part of a larger scheme. That this is true is common knowledge, and the final object of the Tramway Committee of the London County Council is to get tramways on the bridges over the Thames, so that the northern and southern tramway systems might be joined up. The shallow tunnel under the new street was to be the first such link through the heart of London, but the Embankment tramways and those over the bridges would be surface lines. The fear was expressed accordingly that if the present Bill was passed, the lines on the Embankment would be used in the future as a reason for granting parliamentary powers for the lines over the bridges. That tramways would have hampered the traffic on the London bridges is sure, and Parliament has yet to be convinced that the business and general traffic should give place to tramway passengers. The action of the House of Lords will commend itself to many who have expert knowledge of the increased possibility of narrow and crowded roads with automobiles. In any case the London County Council would have done better to have shown their full scheme, and to have stood or fallen by that.

NEXT WEEK.

This week we hardly expect our editorial efforts to be carefully perused, but we hope that the above heading will remind a large section of electrical engineers that they can have a good time in London next week under the guise of attending business meetings. In the first place, the Incorporated Municipal Electrical Association is holding its annual convention in London, which will last over from Wednesday, July 2, until Saturday, July 5, both days inclusive. Mr. J. H. Rider, the electrical engineer to the London County Council tramways, is president this year, and, as is only right, the chairman of the London County Council will welcome the members of the association at the first general meeting on Wednesday, which will be held at the Institution of Mechanical Engineers. The item in the programme of this association which involves the greatest change from that of previous years is the abandonment of the annual dinner in favour of a smoking concert. The advantage is that, instead of half a dozen gentlemen speaking for the company when they would rather be smoking, the whole of the members can talk at the same time. The programme of papers to be read and of visits to be paid is an exceptionally good one, so that if municipal engineers are forced by the holding of the meeting in London to join in the Coronation festivities, they can explain to their town councillors that they required a quiet time in the Metropolis in order to put together what they wish to say in the important discussions which are sure to follow the reading of these papers. The other meeting which is of great interest to all electrical engineers, is that of the congress of the Union Internationale Permanente de Tramways. The congress of this union opens on Monday, June 30, at noon. The President of the Board of Trade has under-

Digitized by Google

taken the opening ceremony, which will take place in Berners Hall at noon. Full programmes of both these congresses will be found in this week's issue.

ANTICIPATIONS.

Now Mother Shipton's numbered with the dead;
Her all-prophetic cloak is on my head;
And thus I prophecy how things will hap,
And Time will verify what I have said.

When Coronation fever's in the air
O ye who 'wait delivered goods, beware!
This chief excuse will cover all delays—
"The Holidays": and so for this prepare.

The while the great procession passes by:
I know that Edward Rex will surely sigh
To change his chariot for a motorcar,
And haste the crawl into a wingless fly.

When at the end of that all-glorious day:
A boist'rous wind doth on the gas-jets play
OD AVE E NG is all that will be seen,
Save where the "juice" the words complete display.

Where such illuminations glow the skies,
Put up in haste by those who money prize
More than good name—I see a sad surprise
For him who on pre-figured amps relies.

Then when the aftermath comes, sweet and sour,
And men return to work with smile or glower,
The cheerful face will show the weekly wage,
The sad: gets paid, *when* working, by the hour.

B. C. H. J.

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

We beg to remind our readers that the seventh annual convention of the above association opens in London at the Institution of Mechanical Engineers, Storey's-gate, Westminster, on Wednesday, the 2nd prox. At 10 a.m. on that day Mr. J. H. Rider will deliver his presidential address. The full text of the official programme of the meeting was given in our last issue. The convention closes on Saturday, July 5.

A CONTRIBUTION TO THE KNOWLEDGE OF ROTATING HYSTERESIS.*

BY M. SCHENKEL, DRESDEN.

The tests here described were principally undertaken for the purpose of discovering whether the value of the rotating hysteresis loss decreased to zero again at very high inductions after having risen from zero to a maximum value. The experiment has only been attempted three times up to the present—by Bailey, the discoverer of the effect, by Messrs. Beatty and Clinker in England, and, finally, by Messrs. Graw and Hieke in Vienna. Two of these experimenters used a thin disc of iron suspended between the poles of an electromagnet, so as to obtain high saturations.

The present writer, on the other hand, determined to employ as great an amount of iron as possible. In order to obtain the high inductions, it seemed best to employ a magnet with conical pole-tips, and as this magnet had to be of considerable size, it became necessary to rotate the iron sample rather than the magnet. The magnet was of dynamo steel, and could stand 25,000 ampere-turns continuously, or 40,000 for a short time. The bore of the poles was 37mm. diameter and 40mm. long, and the rotating iron cylinder was 35mm. diameter and 17·5mm. high. It consisted of dynamo stampings, supplied by Messrs. Siemens and Halske, ·35mm. thick, insulated with thin paper. Obviously no uniform distribution of the flux could be expected in the sample, and no attempt was made to determine the distribution; the average value of the induction, B, alone was measured by means of a ballistic galvanometer. Wherever mention is made, in the following, of induction, the average induction is to be understood. The highest value attained in the experiment was 28,000 = B with 26,000 ampere-turns.

As a free suspension in the magnetic field was not permissible owing to the enormous magnetic forces, it was necessary to employ self-centering bearings. It was, therefore, impossible to measure the turning moment required for hysteresis alone. A certain torque due to friction was, perforce, included in the measurements. The following method of test was selected in order to allow for this: The iron sample, E (Fig. 1), rests on a bush, B, kept as small as possible, which is free to rotate on the truly cylindrical axle, A, and carries a pulley, R. The sample, E, can be rotated by means of a cord passed round the pulley, R. This cord passes through a sort of belt dynamometer, which is made very light, and enables the torque transmitted to R to be measured. The internal friction of this dynamometer was separately investigated, and found to be very small. The axle, A, rests in the upper and lower self-centering bearings, L L, and is held from above by a bifilar suspension, which rotates with it

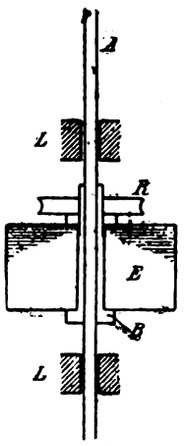

Fig. 1.

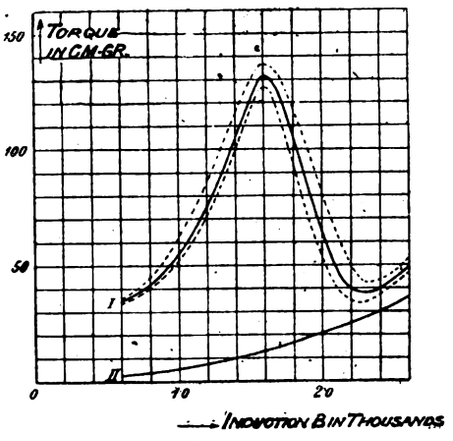

Fig. 2.

On account of the rotation the torque on this bifilar suspension had to be measured by the height through which the object is raised, and not by the angle of deflection. It is unnecessary to provide the sample, E, with any support against sliding along the spindle, as the magnetism itself keeps it suspended between the poles.

The principle of the measurement of the torque due to hysteresis for any induction B was as follows: (1) Axle A and sample E rotate in the same direction and equally fast. The latter point was very exactly ensured by means of small stroboscopic discs fixed to A and E. Both measuring instruments—the dynamometer and the bifilar suspension—give a reading of torque. The sum of these readings, D_1, is equal to the torque, D_H, for hysteresis + the torque for friction in the self-centering bearings, L. (2) Axle A and sample E rotate in opposite directions, but at the same speed as above (determined by means of stroboscopic discs). Then the bifilar suspension measures the sum, D_2, of the torques $D_L + D_B$, where D_L is the torque of the axle, A, in the bearings, L, and D_B is the friction of the axle, A, in the bush, B. The dynamometer measures the sum, D_3, of the torques $D_B + D_H$.

Three independent equations are therefore obtained:

$$D_1 = D_H + D_L;\ D_2 = D_L + D_B;\ D_3 = D_B + D_H;$$

from which D_B can be determined. The friction losses are entirely eliminated without making any further assumption than the quite justifiable one that these losses remain constant during the time of each single test.

Curve 1 (Fig. 2), connecting the torque required for hysteresis and eddy currents in centimetre-grammes with the induction, B, at 10 periods per second, was obtained in this way. By making similar tests with various periodicities up to 30, but constant induction, B, it could be shown that

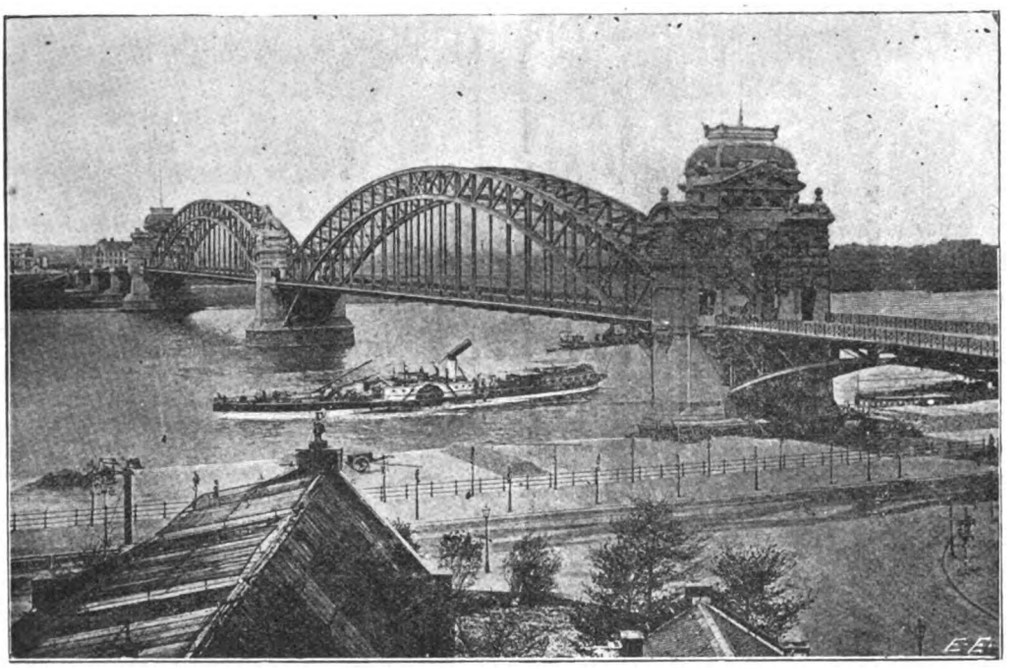
* Translation in abstract from the *Electrotechnische Zeitschrift* for May 15, 1902.

Digitized by Google

the torque increased proportionately to the periodicity; this points to the fact that the eddy-current torque increases in proportion to the periodicity whilst the hysteresis torque remains constant. The amount of the eddy-current torque could also be obtained from these tests at various inductions, and this is shown in Curve II. (Fig. 2). It should be mentioned that Curve I. is drawn through 49 points, and the dotted parallel curves indicate the limits of accuracy—*i.e.*, none of the points employed lay without these boundaries. The difference between I. and II. shows the torque for hysteresis alone.

The tests tend to confirm the results of the above-mentioned experimenters. Increasing first slowly, then more quickly, and then again more slowly, the hysteresis reaches a maximum value at a B of 16,000. After this it falls off remarkably quickly, and appears to approach the zero line asymtotically. At a B = 23,000, however, it is already reduced to only about 8 per cent. of its maximum value. As the volume of the iron sample, E, was 15 cubic centimetres, the curve shows that the watts lost at 10 periods were $(131 - 13)\frac{2\pi \times 10}{15} = 495$ C.G.S. = ·485 watt per cubic centimetre for an induction B = 16,000, whilst they were only ·04 watt for B = 23,000.

It may be pointed out, in conclusion, that the comparatively large proportion of the total loss formed by the eddy-current loss is due to the arrangements of the experiment by which the production of eddy currents was rather favoured.



The New Rhine Bridge, Dusseldorf.

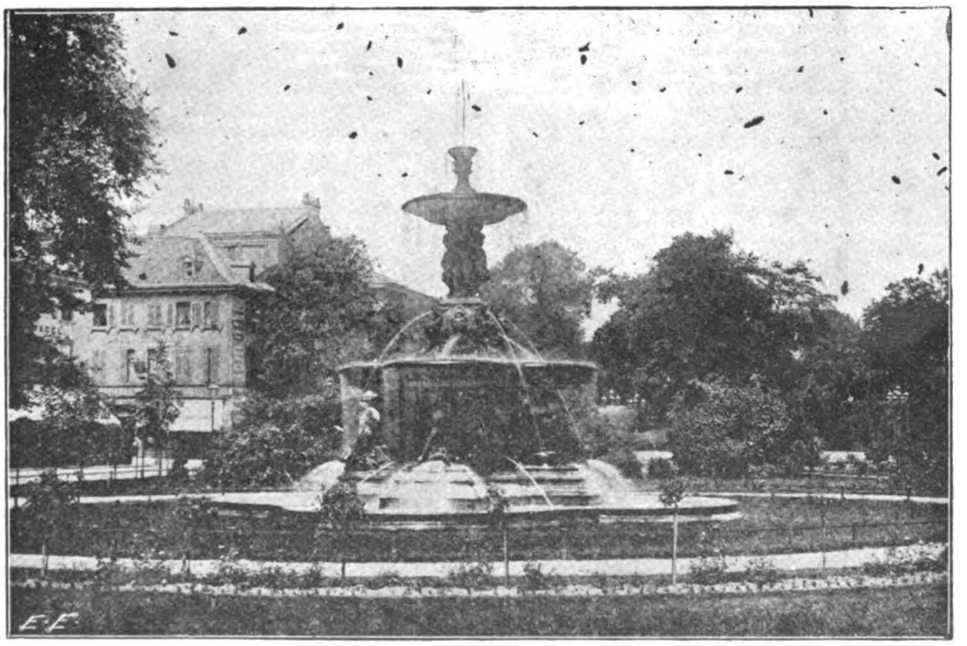
THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

TENTH ANNUAL MEETING, DUSSELDORF.

[BY OUR OWN CORRESPONDENT.]

(Continued from page 880.)

The annual report having been read by Mr.. Kapp, a proposed standard construction for flexible wire used in connection with hanging lamps was submitted to the meeting. The following is a translation: "The copper contained in the flexible wire has a sectional area of 0·75 square millimetres. The copper core consists of tinned wires having a maximum diameter of 0·3mm., and made into a cable. The core is first covered with cotton, and then encased in vulcanised rubber having a thickness of 0·6mm. Two cores thus insulated are to be combined with a strengthening cord or strand made of suitable



A Park Scene, Dusseldorf.

Digitized by Google

material, the whole being then enclosed in a braiding of cotton, hemp, silk, or similar material. The strengthening cord or strand may also be arranged double on both sides of the cores. If the strengthening strand is of metal, it must be taped or braided. The common braiding of the wire can be dispensed with, but the rubber-covered cores must in that case be separately braided. The twin flexible so constructed must be capable of withstanding an alternating pressure of 1,000 volts when in a dry condition." After some discussion, these recommendations—formulated, it should be mentioned, by the committee of the Verband entrusted with the consideration of questions relating to wires and cables—were adopted.

Badge worn by Members of the Verband, Dusseldorf Meeting.

It will be seen that the object of the standard is to obtain a flexible wire, the mechanical strength of which shall be independent of the copper core and its insulation. Whether a special form of lampholder and separate connection of the carrying strands to such lampholder would be entailed by the innovation did not transpire. But it seems to us that unless such special provision be made, the object of the improvement will be defeated.

LEGAL INTELLIGENCE.

CABLE RIGHTS.

On Monday in the House of Lords, Lord Macnaghten (presiding) and Lords Brampton, Robertson, and Lindley, heard arguments in the case of the West India and Panama Telegraph Company, Limited *v.* the Cuba Submarine Telegraph Company, Limited, which came up on appeal from an order of the Court of Appeal, affirming, with some variations, a judgment of Mr. Justice Farwell.

The action was commenced in the Chancery Division by the respondents for the purpose of asserting and enforcing certain alleged rights of theirs under agreements made in 1870 and 1877. The substantial question was the meaning of the words "telegraph communication" in the agreement of 1870, the point at issue being whether the appellants and respondents were, as the appellants contended, in telegraph communication only with such places as they respectively serve by their own lines, and lines which are or may be leased to them respectively, or over which they respectively have or may obtain control. The main contention of the respondent company, on the other hand, was that the appellants were bound to account to them for payments received in respect of messages which did not pass over the respondents' system, but which were destined for any place with which the respondents in their capacity as members of the public could communicate by telegraph in the ordinary course of business. Mr. Justice Farwell decided in favour of the respondents, and with certain variations his judgment was affirmed by the Court of Appeal. Hence the present appeal.

At the conclusion of the arguments, their Lordships now held that the decision of the Court of Appeal was right, and they accordingly dismissed the present appeal with costs.

THE HIRAM MAXIM LAMP COMPANY.

Before Mr. Justice Farwell in the Chancery Division on Friday, **Mr. C. E. Jenkins, K.C.,** mentioned the case of the Hiram Maxim Lamp Company, Limited, *v.* Henry Wardlow and others. He had a motion to make, but proposed to postpone it till Tuesday.

Mr. Upjohn, K.C., for the defendants, dissented, and **His Lordship** asked what were the facts of the case.

Mr. Jenkins said the action was brought by the Hiram Maxim Lamp Company against certain gentlemen, who were directors of that company. Though the action was brought in the name of the company it was really brought upon the authority of the Hiram Maxim Electrical Engineering Company, which controlled the shares in the lamp company; and it asked for an injunction to restrain the defendants from making a certain call and other relief of that kind.

His Lordship, reading from the writ, said it was sought to restrain calls, and an order to prevent the directors from summoning an ordinary general meeting.

Mr. Jenkins said the plaintiffs had a good cause of action against the directors, who refused to give them a list of shareholders in order to call a meeting. The result was that they were afraid the affairs of the company were not being properly conducted.

His Lordship reviewed the whole course of the litigation, and said there was a limit to the delays which had already ensued, and he dismissed the application for a stay accordingly. He also refused Mr. Jenkins's application for leave to appeal.

A TELEPHONE CASE.

At Darlington County Court on Wednesday last week, the Rev. Mr. Eckersley, the owner of property on the High-row, Darlington, sought to recover damages and an injunction against Messrs. Cox, Walker, and Co., electrical engineers, for fixing a telephone wire to the chimney of the plaintiff's property, occupied by Messrs. Lipton and Co. It was stated that a similar thing had been done eight years before, and action had to be taken to get its removal. Now the offence had been repeated, and though it had been taken away on demand, a wire had, later, been placed in front of the plaintiff's property.

The defence was that the wire had been fixed by mistake on plaintiff's instead of another chimney which joined it, where the company had leave to fix the wire, and evidence was given to this effect.

His Honour refused an injunction, but gave judgment for the plaintiff for £1 damages and costs.

COMPANIES' MEETINGS AND REPORTS

W. T. HENLEY'S TELEGRAPH.

On Friday the ordinary general meeting of the shareholders in this Company was held at the Cannon-street Hotel, Mr. Sydney Gedge presiding.

The **Chairman,** in moving the adoption of the report, stated that the ordinary and preference share capital remained unaltered. There was power to issue £200,000 of each, and there had actually been issued £175,000 of each. Before long, however, it might be necessary to increase the capital to the larger amount. The mortgage debenture stock remained at £50,000 in the balance-sheet, because it was kept alive for special reasons, but the amount was being annually reduced. The net profit for 1901 was £57,449, which was rather more than that of the previous year, and they brought forward £24,000. The result was that the directors were able to ask the shareholders to confirm their declaration of a dividend for the whole year of 20 per cent., of which 15 per cent. had already been paid. Referring to the breakdown in the negotiations for joining hands with the Callender's Cable and Construction Company, Mr. Gedge expressed regret that certain difficulties had arisen as to the terms of the proposed amalgamation, which, in the view of both Boards, rendered such a step for the present impracticable. Although the amalgamation had failed for the present, there was no reason why it should not take place at a future date.

Mr. George Sutton, in seconding the resolution, stated that the industrial crisis in Germany had played havoc with part of their business, but, nevertheless, profits had been rather larger. The American competition had also affected them to some extent, but not as regarded prices. As regarded the business this year, he was perfectly satisfied with the returns up to May, and he had no doubt that for the remainder of the year the business would be as good.

The resolution was unanimously adopted, and the dividend recommended declared.

MOTOR MANUFACTURING COMPANY.

An extraordinary meeting of this Company, held last month, having approved an agreement for the sale of the undertaking to a new company to be incorporated under the same name, part of the consideration being the allotment to shareholders of 252,966 shares in the new company of 5s. each, with 3s. per share credited as paid up, Mr. Alfred Burgess, the liquidator, has now issued a circular announcing that these shares are ready for distribution. In this document he gives a rough estimate of the financial position upon which the new Company will commence business. In addition to the share capital—£63,241—there are debentures for £20,000, while creditors of the old company to be paid by the new company (including a considerable sum for deposits on cars ordered by customers) figure for £16,000. On the other side of the account the following amounts are shown: estimated amount to be received from debtors of old company, £3,000; work in progress, complete cars, and stock, £36,445; machinery, £23,000; tools, £3,000; patterns and drawings, £500; cash to come in in respect of the 2s. per share liability on the 252,966 shares, £25,296; and buildings leases, etc. (cost £20,500), £8,000. The liquidator adds that there are orders in hand at the present time to the extent of £23,264, provided they are executed quickly. It has been ascertained beyond doubt that the principal cause of the loss sustained in the past is the fact that the company constructed too many different types of motor vehicles. He understands that it is proposed to reduce the number of standard types to three—that is: (1) a single-cylinder car; (2) a two-cylinder car; and (3) a four-cylinder car—and that the cylinders and many portions of the engines of each of these

Digitized by Google

three types will be absolutely interchangeable, also that the saving thus effected in the cost thereof will be considerable.

LISBON ELECTRIC TRAMWAYS.

The report of the directors for the year ended Dec. 31 last states that the conversion of the system was continued, with the result that by the end of the year more than one-half of the lines were in operation electrically, and there was every prospect of the rapid completion of the whole system as originally provided for. The working of the tramways by animal traction showed a loss, even under the best conditions, and the numerous interruptions, due to the construction, added to it considerably. The first line was opened to the public by electric service on Aug. 31, and the earnings, which up to the introduction of electric traction had been steadily falling off, immediately increased, and the results of each new service, opened to the public from time to time, have been equally satisfactory. Although the four months under review cannot be taken as an indication of the earning power of the Company, the directors feel confidence in stating that in their judgment the Company can safely look forward to a prosperous career. The accounts show a profit on working of £1,677, and a net debit balance to profit and loss after payment of debenture interest of £28,025.

WEST AFRICAN TELEGRAPH.

The report of the directors for 1901 states that the revenue for that period amounted to £75,554, against which £20,674 is charged for ordinary expenses and £17,720 for expenditure relating to repairs of cables, etc. After providing £95 for income tax, there remains a balance of £37,065, to which is added £322 brought forward, making a total available balance of £37,387. From this balance there has been deducted £7,508 for interest on debentures and £16,566 for sinking fund, leaving £13,312, out of which the directors propose to place £13,000 to the general reserve fund, and carry £312 forward. The revenue for the year under review includes a further sum of £12,000 in respect of subsidy due from the French Government, but which has not been paid. This arrear, together with the sums withheld in previous years, now amounts to £80,415. The negotiations, however, with the French Government, referred to in the last report, have been successfully concluded since the date of these accounts, and the first instalment of £112,000, due from the French Government on account of the cables purchased by them, has been received.

THOMAS PARKER, LIMITED.

The directors' report for the year ended April 30, 1902, states that, after writing off the various depreciations, the balance standing to the credit of profit and loss account is £9,049. 9s. 9d. Out of this the directors propose to pay a dividend at the rate of 10 per cent. per annum, less income tax, amounting to £7,060. 7s. 2d., and to carry the balance—£1,987. 2s. 7d.—forward to next year's account. The director who retires by rotation is Mr. R. Armistead, who is eligible, and offers himself for re-election. The auditors, Messrs. Allen Edwards and Smith, also retire, are eligible, and offer themselves for re-election.

UNITED RIVER PLATE TELEPHONE.

The directors of the above Company report that the gross receipts in sterling for the year ended March 31 last in the River Plate were £114.841, as against £109,540 for the year before; and the working expenses in London and the River Plate £60,345. After deducting debenture interest and interim dividends on preference and ordinary shares, and adding transfer fees and interest on investments, there remains a profit of £33,405, to which must be added £6,058 brought forward from the previous year, leaving an available balance of £39,464. After transferring the sum of £20,000 to reserve fund, which will then amount to £75,000, the directors recommend that a final dividend of 4½ per cent. be paid upon the ordinary share capital of the Company, making, with the interim dividend paid Dec. 31 last, a return of 7 per cent. for the year, and that the balance of £6.414 be carried forward.

ANGUS ELECTRIC LIGHT AND POWER.

The report of the directors for the half-year states that the works at Montrose and Brechin were completed in July, since which time a satisfactory supply has been maintained in both towns. At the end of the year the equivalent of 2,066 8-c.p. lamps were connected in Montrose and 2,790 in Brechin, and up to the present time 2,672 additional lamps have been applied for in Montrose and 1,502 in Brechin, making a total of 9,030 in the two towns. The directors consider this a very satisfactory start for towns of this size. The result of the six months' working, after paying all expenses, has been a net profit of £42. 4s. 5½d., which it is proposed to carry forward to next account. The statement of electricity generated, sold, etc., shows that 12.513 units were generated in Montrose and 18,233 in Brechin. Public lamps used 3,407 units in Montrose and 5,605 in Brechin, and private consumers 5,895 in Montrose and 5,348 in Brechin.

ELECTRIC AND GENERAL INVESTMENT.

The report of the directors for the year ended May 31 last states that the profit and loss account shows a gross profit on the transactions of the year of £32,247. After deducting all general charges and the interim dividends already paid on the preference and ordinary shares, and providing for the proportion of the final dividend accrued on the preference shares to May 31, there remains a net balance of £20,470. Of this sum the directors propose to carry £10,470 to the contingencies account in order to strengthen the funds available for dealing with further business. This will leave an available balance of £10,000 for the payment of dividends, as noted in our last issue.

APPOINTMENTS VACANT.

Assistant Superintendents (5), Indian Telegraph Department, commencing salary 4,200 rupees, June 30. See advertisement.

Distribution Engineer, London County Council Tramways Department, £350 per annum, July 14. For particulars see advertisement.

Charge Engineer, Southwark Electric Station, Penrose-street, Walworth-road, S.E., £2. 10s. per week, July 2. See advertisement.

Assistant Superintendent of Mains, Edinburgh Corporation, £150 per annum, July 7. See advertisement.

Foremen Linesmen (3), Manchester Corporation Tramways, £2. 10s. per week, July 5. See advertisement.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Chester.—The Corporation invite tenders for accumulators and booster. Tenders by July 7.

Shanghai.—The last day for receiving tenders for the proposed municipal tramway and motor 'bus service is June 30.

Madrid.—The Department of Agriculture require a number of meters and instruments valued at £1,000. Tenders by June 30.

Sunderland.—The Corporation invite tenders for the supply of permanent way, overhead equipment, and cables. Tenders by July 9. See advertisement.

West Ham.—The Council invite tenders for 50 double-deck electric tramcars, complete with electrical equipment. Tenders by July 8. See advertisement.

Romford.—The Urban District Council invite tenders for the construction and maintenance of electricity supply works in the district. Tenders by June 30. See advertisement.

Valparaiso.—The Municipality are inviting tenders for electric lighting and tramways. We understand that particulars may be obtained from the Chilian Consul. Tenders by Sept. 1.

Leskovatz (Servia).—The Société d'électricité de Leskovatz require two turbines of 200 h.p. and two dynamos for three-phase current; also accessories for a power installation with a radius of 11 miles. Tenders by July 1 (14).

Bexley.—The Urban District Council invite tenders for points and crossings and boilers. Specifications, etc., may be obtained from the engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, Westminster, S.W. Tenders by July 7.

Lowestoft.—The Corporation invite tenders for the construction of tramways, rails, fishplates, and bolts, and permanent-way construction. Specification, etc., may be obtained from Mr. R. Beattie Nicholson, town clerk, Lowestoft. Tenders by July 12.

Launceston (Tasmania).—The Corporation invite tenders for polyphase generating, transmitting, and distributing plant and apparatus, transforming apparatus, reconstruction of existing plant, and enclosed arc lamps and accessories. Tenders by Sept. 15. See advertisement.

Willington Quay.—The Willington Quay and Howdon Industrial Society, Limited, invite tenders for supplying and fixing electrical apparatus as required for power and light at their Bewick-road premises. Specification, etc., can be had on application. Tenders by noon on July 4.

Falkirk.—The Corporation invite tenders for storage batteries, generators, transformers, switchboard, cable work, crane, lamps, and fittings. Specifications can be inspected at Messrs. Burstall and Monkhouse, 14, Old Queen-street, Westminster. Tenders by July 14. See advertisement.

Gillingham.—The Urban District Council invite tenders for the supply and erection of two water-tube boilers, steam and exhaust piping, condenser, cooling tower, high-speed engines, three triphase

Digitized by Google

alternators (250 kw. each), switchboard, underground cables, arc lamps, crane, and well. Tenders by July 17. See advertisement.

Ipswich.—The Corporation invite tenders for the supply, delivery, and erection at the generating station, Constantine-road, Ipswich, of engines and dynamos, storage battery, overhead hand travelling crane, feeders, mains, and road work, permanent-way construction of tramways, and arc lamps. Tenders by July 5. See advertisement.

London, S.W.—The London County Council invite tenders for the supply, delivery, and erection at the Council's temporary generating station at Loughborough Junction of steam, exhaust, feed, and other piping, valves, etc. Specifications and other particulars may be obtained from the County Hall, Spring-gardens, S.W. Tenders by July 8.

Epsom.—The Urban District Council invite tenders for the supply and erection of semi-marine dry-back boiler, with fittings, etc.; ejector condensers, circulating pumps, and pipework; spray cooling pond; steam, feed, and drain pipes, etc.; and one 150-kw. steam dynamo (vertical enclosed high-speed engine) and switchgear, etc. Tenders by July 18. See advertisement.

Nuneaton and Chilvers Coton.—The Electricity Committee invite tenders for the supply and delivery of private lighting cables (paper), public lighting cables (rubber), joint-boxes and compounds and 20 arc lamp columns, with incandescent brackets, complete with arc and incandescent lamps, cut-outs, switches, resistances, and all other accessories. Tenders by June 30.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramways and Electricity Board invite tenders for the supply, delivery, erection, and construction of three 500-kw. steam-driven, direct-coupled three-phase alternators, etc.; three 50-kw. steam-driven, direct-coupled continuous-current exciters, etc.; and permanent way, including copper bonding and conduits for cables. Tenders by July 7. See advertisement.

Teddington.—The Urban District Council having obtained a provisional order enabling them to supply electricity within the urban district of Teddington, invite tenders from persons and companies able to carry out electrical undertakings, stating terms upon which they would be willing to take over such provisional order, and to submit a scheme of electric lighting for the district, with particulars of cost. Tenders by July 12. See advertisement.

Chester.—The Corporation invite tenders for construction and reconstruction and electrical equipment of tramways, alteration, adaptation, and equipment of shed, tramway cars, and general equipment (preferably for the whole, or in sections)—viz.: permanent-way construction (length of route about 4,678 yards) and car-shed; bonds; overhead equipment; and cars. Specifications, etc., may be obtained from Mr. I. M. Jones, city surveyor, Town Hall, or Mr. F. Thursfield, city electrical engineer, New Crane-street. Tenders by July 7.

Norway.—The Board of Trade notify that tenders will be received at the Norwegian State Telegraph Department, not later than noon on July 7, for the supply of 25b-pair and 204-pair telephone cable, and for Leclanché battery glass. Specifications and conditions can be seen in the Technical Department of the Board of Telegraphs, Christiania. Apart from the usual customs duties, a preference of from 10 to 15 per cent. is given to native manufactures. The Board also notifies that tenders will be received up to 11 on July 1 for the supply to the Italian navy of American pitch pine to the value of £2,573, to be delivered at the Royal Arsenals. Particulars may be obtained at the Board of Trade Offices (Commercial Intelligence Branch), 50, Parliament-street, any day between the hours of 10 and 5.

RESULTS OF TENDERS.

Swansea.—The Town Council have accepted the tender of the Mannesman Tube Company, Limited, for steam pipes, valves, etc., at £1,065.

London County Council.—The tender of Jackson Bros. to execute the wiring and supply the fittings for an electric light installation at the Euston-road station, for £352. 3s. 6d., has been accepted.

Slot Meters.—The Rochdale Electric Company, Limited, have just received what is probably the largest order for an electric prepayment meter ever placed—viz., 1,000 slot meters for the Northern Counties Electric Supply Company, Limited, Newcastle. Last year's contract between the same parties was 500 meters.

Hackney.—The Borough Council have accepted the following tenders for the extensions of their municipal electricity works: (Section R)—boiler-house plant, Babcock and Wilcox, Limited, three water-tube boilers, feed pump, steam and water pipes, etc., £6,910. 5s.; (S)—water-softening plant (capable of softening 10,000 gallons of water per hour), Babcock and Wilcox, Limited, £1,120.

Paisley.—The Corporation have accepted the following tenders for the supply of plant to the electric lighting works: D. Adamson and Co., Dukinfield, near Manchester; Davey, Paxman, and Co., Limited, 78, Queen Victoria-street, London, E.C.; British Schuckert Electric Company, Limited, Clun House, Surrey-street, Strand, London, W.C.; Korting Bros., 53, Victoria-street, London, S.W.

London County Council.—The following quotations have been received for the electric lighting of the Camberwell and Battersea fire stations and the Battersea Park-road sub-station:

Battersea station.

Cramer and Co. (accepted)	£107	10	0
D. Assersohn	122	10	0

Jackson Bros.	60	19	0
Lawrence and Co.	67	10	0
Barron and Woodward	90	10	0

Greenock.—The Corporation have accepted the tender of the India Rubber, Gutta Percha, and Telegraph Works Company for the supply and erection of one 300-kw. steam dynamo, with steam and exhaust piping, at £3,160.

BUSINESS NOTES.

LIGHTING AND GENERAL.

Llandudno.—The Urban District Council have increased the salary of Mr. Allen, assistant electrical engineer, by £20.

Northfleet.—Steps are now to be taken to obtain an offer for the purchase of the District Council's electric lighting order.

Brighton.—The Telephones Committee hope to be in a position to commence the work shortly, but are unable to specify a date when telephone connections can be made.

Baxterley.—Arrangements are being concluded between the General Post Office and the Rural District Council for a telegraph line from Atherstone to Baxterley.

Coventry.—The Electric Light Committee have been authorised to dispose of plant No. 1 at the works. The plant when purchased cost £1,216, and the sale will be advertised.

Salford.—A circular letter has been issued to consumers of electricity by Mr. C. D. Taite, electrical engineer for the borough, giving particulars of yet another change in the system of charging.

Peterhead and Fraserburgh.—With regard to trunk telephonic communication, we learn that the Postmaster-General is instituting an active canvass of the business firms and private residents at both towns.

Bath.—The Works Committee have engaged Mr. A. J. Taylor to carry out the provision of the electric baths on the usual architect's commission. The cost will be £250 or £260, plus £12 for the electric fittings.

Chesham.—The Urban District Council have settled the terms of the electric light agreement, and it is stated that there is nothing to prevent the company being formed now and getting their capital together.

Taunton.—On Monday important extensions to the Corporation's electric light works were inaugurated. The works have now been brought thoroughly up to date at a cost of £18,000, and the capacity at the station is 1,600 h.p.

Ebbw Vale.—The District Council have received an offer from the Ebbw Vale Company to supply the Council with as much electrical power as they required for lighting purposes at 2d. per unit, the suggested minimum being 50,000 units.

London Gazette.—The partnership existing between F. F. Bennett, A. Ward Thomas, and J. W. Donaldson (trading as Bennett and Ward Thomas), electrical engineers, Winter's-buildings, St. Ann's-street, Manchester, has been dissolved by mutual consent.

Rawmarsh.—The Urban District Council have decided to take the necessary steps to obtain an extension of the electric lighting order granted in 1898, and a deputation has been appointed to wait upon the Secretary to the Board of Trade for this purpose.

Southwark.—The last report of the Electric Light Committee shows that up to last week 25,385 8-c.p. lamps had been connected to the mains for light, and for power 2,443, or an equivalent to 24,828 8-c.p. lamps, being an increase of 275 8-c.p. lamps during the past fortnight.

Mansfield.—The committee have accepted an offer of Messrs. Thomas Parker, Limited, to completely cancel the order for the third set of dynamos on condition that they have the option of supplying this machinery at the contract price when further plant is ordered.

Luton.—Current will be supplied free of charge to any of the Corporation's consumers who may desire it for exterior illumination purposes from 9 p.m. to 12 midnight on June 26, 27, and 28; all other expenses connected therewith are, of course, to be borne by the consumers.

Digitized by Google

Textile Factories.—One electrical manufacturing company alone in the United States has installed 40,000 h.p. of electric motors in textile mills. Germany, Austria, Russia, and Italy have a number of electrically-driven textile factories. Those in Italy total nearly 10,000 h.p., varying from 120 h.p. to 2,000 h.p. each.

Wireless Telegraphy.—A Laffan telegram from New York says: "The United States Navy Department has ordered all ships undergoing repairs to be fitted with wireless telegraphy apparatus. Before finally installing any system, experiments will be made to determine the relative merits of four European systems, including one English."

York.—Mr. G. H. Barnby Holmes, pupil of the city electrical engineer, has been appointed to the position of junior assistant engineer, at a commencing salary of £78 per annum. Mr. F. B. Walker, of Bradford Corporation electricity department, has been appointed chief clerk in the Corporation lighting department, at a commencing salary of £120 per annum.

Swansea.—The engineer's last report states that the number of consumers now on the books is 222, with the equivalent of 27,191 8-c.p. lamps. It has been resolved that extensions of mains be made in St. Helen's-avenue and Francis-street, estimated cost £110; Pier-street, £26s. 2s. 6d.; Humphrey-street and Ffynone-lane, £35; Mount-pleasant, £70.

Dover.—A rehearsal of the Coronation illuminations at Dover showed that, independent of the general illumination of the town, which is very extensive, the municipality are responsible for about three miles of electric festoons, of which nearly two miles outline Dover Bay and the new Prince of Wales Pier, with prominent buildings intervening.

Falmouth.—At the last meeting of the Town Council the Lighting Committee reported that they had considered proposals from Mr. Purvis, on behalf of Messrs. Crompton and Co., Limited, for the electric lighting of the borough, and recommended that Mr. Purvis be asked to come down and meet the General Purposes Committee on the matter. The report was adopted.

Cardiff.—The estimated revenue for the past month from the electric lighting scheme of Cardiff was £909, or 30 per cent. above the revenue of the corresponding month last year. Conduits are now being laid to the centre of the town for a continuous current, to replace the present alternating current, and the extensions for Woodville-road and Splott are being pushed forward.

Medomsley.—The Parish Council have accepted an offer from the Consett Iron Company, Limited, with reference to the Council's application for electric power for lighting about 30 lamps in the neighbourhood of Medomsley, intimating that they were prepared to enter into a similar agreement for this purpose with that now existing between the Council and the company.

Sleaford.—At the last meeting of the District Council Mr. Clare, C.E., and Mr. Yates, electrical engineer, submitted plans of motors for pumping in connection with the new sewage farm, for which a loan of £3,000 has been applied for. It was urged that electric power would cost more than a gas-engine, but it was resolved, as the Council possess electric works, to instal an electric motor at a cost of £267. 11s. 2d.

Dumbarton.—The Bill to confirm the provisional order of the Board of Trade for the authorisation of a system of electric light in the burgh now before Lord Newton's Committee of the House of Lords is opposed by the North British Railway Company, the Lanarkshire and Dumbartonshire Railway Company, and the Dumbarton and Balloch Joint Line Committee. The preamble of the Bill has now passed the committee of the House of Lords

Floating Dock.—An electric floating dock has been built for New York harbour, and is probably the first of its kind anywhere. It consists of three compartments, and has a total length of 492ft. The special feature of the dock is the employment of electricity for pumping, for which purpose two pumps are fitted to each compartment having a motor of 75 h.p., and it is stated that a vessel of 9,000 tons can be raised out of the water in 51 minutes.

Train-Lighting.—It is stated that in a short time the trains of the London and North-Western Railway running between Nuneaton and Hinckley, Leicester, etc., and Nuneaton and Bedworth, Coventry, Kenilworth, Warwick, and Leamington, will be lighted by electricity. Only a few of the trains will be lighted to start with, the others will follow in due course. At other junctions on the North-Western system such a course has been in vogue for some time.

Gwyrfai.—An application was made to the Rural District Council last week, on behalf of Mr. Assheton Smith, for the Council's support to a provisional order enabling him to construct works for the supply of electricity for the Dinorwic quarries and the dwelling-houses in the parishes of Llanddeiniolen and Llanfairisgaer, and a portion of the parish of Llanberis. A committee of local representatives of each of the parishes in question was appointed to consider the matter and to report thereon.

King's Lynn.—In addition to the figures given in our last issue, we note that the capital expenditure of the electric lighting department up to March, 1902, has amounted to £43,433. The units generated during the last year were 320,609; 286,679 were sold, which leaves 25,648 unaccounted for. This is 8 per cent. of the number generated, against 10 per cent. for the previous year. The total 8-c.p. lamps connected were 14,220, against 10,274 last year. The maximum demand amounted to 210 kw.

Penzance.—The Town Council have obtained sanction to borrow £300 for purpose of erecting a disinfecting apparatus. With reference to the request for permission to borrow a sum for construction of a landing-stage, the Local Government Board stated that the consent of the Board of Trade was necessary. The Board of Trade have informed the Council that under the circumstances stated by the Council they would defer the consideration of the question of revoking the order for electric light for one year.

Chesterton.—The British Electric Supply Company, Limited, intend to apply to the Board of Trade under the Electric Lighting Acts in December next for an order authorising them to supply electricity for public and private purposes in the following parishes and places, all being situated within the county of Cambridge—namely, the parish and urban district of Chesterton, and the parishes of Cherry Hinton, Coton, Fen Ditton, Girton, Grantchester, Impington, Great Shelford, and Trumpington, all in the rural district of Chesterton.

Agencies.—We are informed that Messrs. Easton and Co., Broad Sanctuary, S.W., have appointed Messrs. Rennert and Lenz their sole agents in South Africa, for the sale of the Schmidt patent superheaters, and also for the same territory (with the exception of Cape Colony) for their electric and hydraulic lifts. Matters dealing with these districts will, in future, be dealt with by this firm or their London agents—Messrs. Findlay, Durham, and Brodie, 110, Cannon-street, E.C. Mr. Francis J. Corbrick, 37, West Dulwich Mansions, has been appointed agent for the above for the South of England.

Annfield Plain.—The Urban District Council have received a letter from the Northern Counties Electricity Supply Company with regard to their proposed lighting, in which the company point out that they are to a great extent in the hands of the Durham and Cleveland Company, who have power to supply electricity over their heads. Under the provisional order the Northern Counties Electricity Supply Company have only power as distributors. They were doing their best to push the Durham and Cleveland Company forward, and fully expected to carry out the obligations of the provisional order within the date scheduled therein.

Battersea.—Certain shunt coils, substitution resistances with cut-outs, Whitworth stocks and dies, tiles, charts, and other articles and materials are to be procured for use in the electricity department, and a number of small works carried out. The electric mains are to be extended from near Plough-road at an estimated cost of £84. The committee have been in communication with the Thames Conservators with a view to a reduction in the terms and alterations in the agreement prepared by them relating to the work carried out in the River Thames in connection with the condensing water required at the central electric generating station, but have been unsuccessful.

Sheffield.—The following reductions have been decided upon in the price of energy used for power only on and after June 30, 1902: (1) for all energy used in motors driving hoists, cranes, passenger lifts, and similar machinery, 2d. per unit; (2) for other motors, 1½d. Special terms to long-hour consumers will be granted as follows: (3) to consumers satisfying the general manager as to the continuous running of their motors through the whole of the working hours of each day, 1½d.; (4) to consumers whose motors run continuously day and night, 1d. Consumers who are already connected to the Corporation mains have been asked to declare in writing under which of the above numbers they wish to be classified.

Indian Clubs.—Mr. John Creelman, of Suffern, U.S.A., has invented an illuminated Indian club with which a pretty illusion can be effected. The club has a hollow, perforated body, threaded at the lower end to receive the handle portion. Secured to the handle and adapted to enter the hollow body is an incandescent lamp. Electricity is conducted to the lamp by means of wires passing through the handle, and connected to any suitable source of electric current. When the current is turned on, the light radiates from the numerous perforations in the club. A quick performer of club exercises can give his audience a very fascinating entertainment, especially if coloured lamps be used instead of the ordinary white light.

Huddersfield.—The Local Government Board have declined to sanction the borrowing of money for the costs of obtaining the electric lighting orders of 1890 and 1896—viz., £516. 12s. 8d.—and have excluded the amount from the new sanction of April 9 last. It appeared that the sum had been charged to capital account, and it will now be transferred to depreciation and contingencies account. The Electricity Committee have decided to quote Messrs. David Brown and Sons, who require about 100 b.h.p. for their new works, the following charges for power purposes: if the consumption exceeds 25 units per hour for 2,400 hours per annum, the charge to be ·975d. per unit; 50 units, ·95d.; 75 units, ·925d.; and 100 units per hour, ·90d. per unit.

Sudbury.—The electric lighting scheme is again under serious consideration by the Town Council. At a special meeting on Friday attention was drawn to the following letter from the Local Government Board: "I am directed by the Local Government Board to inform you that they have had under consideration the report made by their inspector, Mr. Law, of the enquiry held by him with reference to the application of the Town Council of Sudbury for sanction to borrow £12,000 for purposes of electric lighting. I am to state that the Board regard the scheme of the Town Council as generally satisfactory, but as the margin of borrowing powers available to the Town Council is insufficient, the Board are unable at the present time to sanction the loan.

Plymouth Fire.—It is reported that when the fire at Messrs. Spooner's was at its height a large telephone standard came down with a terrific crash, consequently the services between the central exchange and the Devonport and Mutley exchanges were cut off. With exceptional smartness the local manager and his staff cleared the telephone wires. The whole of the National Telephone Company local staff were at work late on Saturday night, and started early on Sunday morning, continuing until late in the evening connecting the various wires. The whole of the work was carried out under the direct supervision of Mr. D. J. Barnes, the local manager, and Mr. Drummond, the district manager, inspected the work about noon on Sunday, and expressed himself pleased with the way in which the work had proceeded.

Digitized by Google

Coronation Illuminations.—We understand that the applications for current received by the metropolitan electric light companies come up to their full winter load. The extra applications received by the Westminster equal 50,000 c.p., and that of the Charing Cross and Strand 25,000 c.p. In addition to contracts already noted, we find that H.M. Office of Works has been using the E.L.B. system for part of the work at Westminster Abbey. The same system is also applied throughout the Stock Exchange, then over the great façades of the Prudential Insurance Company and the Gresham Insurance Company, the United Service Club, the Conservative Club and the Devonshire Club, the Temple Gardens, the Hippodrome building, Messrs. Marshall and Snelgrove's, and Messrs. Liberty's, etc. We are informed that the labour-saving qualities of the system are much appreciated.

Ormskirk.—The Guardians at their last meeting discussed a circular letter from the Ormskirk Urban District Council asking the Board (1) if they were in favour of the electric light being adopted for street-lighting; (2) if cables were laid would they probably take the light; and (3) what number of lights would be required approximately. The maximum charge would be 6d. per unit, which was equivalent to gas at 3s. per 1,000 cubic feet. It was agreed that they should for the present hold their hand until they saw whether a company would put down plant in the town of Ormskirk to supply the three urban districts of Ormskirk, Skelmersdale, and Lathom and Burscough, and also to see if there were any prospect of a light railway between Ormskirk and Southport. In the meantime they would reply in the affirmative to the first two questions of the circular.

Pacific Cable.—Mr. Herbert Arnaud Taylor, of the firm of Clark, Forde, and Taylor, engineers to the Pacific Cable Board, has returned from supervising the laying of the southern sections of the all-British Pacific cable between New Zealand and Norfolk Island, Brisbane and Norfolk Island, and Norfolk Island and Fiji. The work was successfully accomplished, though in laying the Fiji section the "Anglia" encountered a terrible cyclone. The new cable ship "Colonia" of the contractors is loading with the "Vancouver" to Fanning Island section, and expected to leave the Thames on July 3. The "Anglia" is expected home on June 25 to load with the Fanning to Fiji section, and should arrive at Fanning by the time the "Colonia" finishes there. According to the *Globe*, the Vancouver-Fanning section, like others, is to be "duplexed" by the apparatus of Dr. Alexander Muirhead.

Furnace.—A new form of resistance laboratory furnace has been invented by Prof. Holborn, of Berlin, which permits temperature up to 1,500deg. C. being attained with ease by use of the ordinary 110-volt electric supply. The furnaces are made in two forms, the first being adapted for heating crucibles and the second for heating tubes 44cm. in length. In both forms of furnace the electric current is conducted through a resistance coil of platinum or nickel wire, wound round a thin porcelain tube or cylinder. The crucible or substance to be heated is placed within this latter, and the space between the outer side of the coil and the containing vessel is packed with asbestos or powdered quartz. Using nickel, the temperature of the furnace cannot be raised about 1,000deg. C. without damage to the coil, but with platinum it is possible to attain a temperature of 1,500deg. C. with a current of 14 amperes and 110 volts.

Electric Baths for Lead-Poisoning.—A scheme for the electric treatment of lead-poisoning and paralysis in the Potteries has long been under consideration, and last week new electric baths for the treatment of these cases were formally opened by the Duchess of Sutherland at the North Staffordshire Infirmary, Hartshill. The Rev. C. H. Simpkinson, as chairman of the committee who have had the scheme in hand, said that the only means by which they could ensure an electric supply to the infirmary was through the Potteries Electric Traction Company, who was not only giving them the electric supply, but also £100 in order to put the whole scheme in working order. Mr. Simpkinson paid a tribute to individual members of the company who had helped in the work, and said that they all owed a debt of gratitude to the Duchess of Sutherland for the way she had set to work to collect the funds.

Lancaster.—From the report of the electrical department we gather that for the second half of the year the price of current for motive power was reduced from 3½d. to 3d. per unit; the charges for public lamps were also reduced from Jan. 1 last. The total net profits are £931. 6s. 2d., as compared with £1,177. 9s. 3d. for the previous year. This sum has been carried to the reserve fund. The total for "sale of current" has increased by £495. 5s. 10d., and for "meter rentals" (owing to new conditions imposed upon small consumers) by £33. 1s. 10d.; the income from public lamps is decreased by £9. 2s. 2d. The total expenditure has increased from £4,782. 2s. 1d. to £5,644. 8s. 5d., coal and insurance being practically the only items which show a decrease. The reserve fund now amounts to £2,131. 6s. 2d. The total capital authorised and borrowed is £35,000, and the amount expended £39,346. 5s. 8d.

Hampstead.—The Borough Council have confirmed the appointment of Mr. John E Pownall as assistant at the electric lighting station. With regard to a recent Sunday failure of the electric light, it appears that the assistant engineer was caught with a sudden overload on the machine that was running, in all probability due to the churches and chapels being lighted up. He broke the circuit on the running machine completely, and suddenly put in a larger one to take the load. For some reason, entirely unaccountable at present, an arc was formed between the machine panel and the adjoining one on the switchboard, which completely burnt the second one up, but not that of the running machine. To put out this arc the engineer broke the field exciting circuit, and this, with the other arc, so blinded him for the moment that he was unable to see the different panels, and this caused some five or six minutes' delay in getting the load on to a further machine. A main is to be laid for the supply of electric current to private consumers in Chalcot-gardens, England's-lane.

Manchester.—At the last meeting of the Telephones Committee, the conclusions at which the deputation who recently visited Glasgow had arrived were reported as follows: (1) That the Glasgow Corporation were satisfied with the success of their municipal telephonic undertaking; (2) that the work appeared to the Corporation to have been satisfactorily carried out in accordance with the original estimates; (3) that the subscribers in Glasgow were satisfied with the system there established. The committee thereupon resolved, "That in view of the approval of the City Council, which has been already given to the establishment of municipal telephony within the Manchester area, and the information now received as to the satisfactory working of the Glasgow municipal telephonic service above set forth, it is advisable that the application to the Post Office for a municipal license on behalf of the Corporations of Manchester, Salford, and Stockport should be proceeded with, and that all the necessary arrangements be entered into by those corporations with this object."

Bridgend.—Mr. H. Percy Boulnois, M.I.C.E., has held an enquiry into an application by the Bridgend Council for powers to borrow £6,900 for electric lighting purposes. From the evidence it appeared that a provisional order for electric lighting was obtained in 1893, but the Council had been unable to utilise it until the recent advent into the district of the South Wales Electrical Company, because of the great expense of laying down generating plant. The electrical company is supplying the energy on a sliding scale, and by an arrangement with the Asylums Committee the Council will be able to get their supply at 2½d. per unit. The Council intend to use the electricity for public lighting, and also to supply private residences and business establishments at a charge of 5d. per unit. An estimate of the outlay and of the annual expenditure and income was produced, showing a profit to the Council of £225. Mr. H. T. Sully, A.M.I.C.E., Bristol, electrical adviser to the Council, gave evidence, and said that in his estimates he had put all he could against the Council in order that they might be on the safe side.

Explosion.—An explosion occurred last week at the works of the Simplex Electric Fuse Detonator Company, Chorley, by which two young men lost their lives and a third man was seriously injured. The material used in the manufacture of the detonators is, of course, highly explosive. The finishing process, which means the attachment of electric fuses, is carried on in a specially equipped shed at a distance of 50 yards or so from the main building. A little further away, in a corner of the enclosed premises, is the magazine, where the gunpowder is stored. The floors and walls of the shed were padded, and the workers wore specially prepared shoes. Mr. Jordan, manager of the works, thinks that the explosion was due to friction, or that the excessive heat may have been a contributory cause. The detonators, though small in size, are charged with a high explosive. It is said that a fall on a hard substance will suffice to explode them. The police have reported the occurrence to the coroner for the district, Mr. Park, of Preston, and it is expected that the inquest will be opened some time to-day. The Home Secretary will also no doubt order an enquiry to be made with regard to the origin of the explosion.

Illuminations at Spithead.—The special correspondent of the *Daily Telegraph* at Portsmouth gives the following interesting account of the preparations for the illumination of the fleet on the evening of the Coronation, on the following evening, and on the night of the review. The arrangements are in charge of the captain of H.M.S. "Vernon," the torpedo school-ship, and to ensure the success of the scheme special officers have been distributed among the ships. On Thursday the myriad incandescent lamps will be switched on at half-past nine o'clock, and the fleet will remain a blaze of brilliant points of light, outlining them from stem to stern, from masthead to truck, in every detail until midnight. White lights only will be used by the warships, and some conception of the dazzling radiance may be gained from the following figures, indicating the number allotted to each type of ship:

	100-c.p. lamps.		16-c.p. lamps.
"Majestic"	3	...	950
"Empress of India"	3	...	850
Second-class battleships	3	...	750
Third-class battleships	2	...	500
Four-funnelled cruisers	3	...	1,000
"Hawke" and "Narcissus" class	3	...	630
Second-class cruisers	—	...	550
Third-class cruisers	—	...	300
"Northampton"	4	...	700
Torpedo gunboats	—	...	260
Destroyers	—	...	150
Torpedo boats	—	...	65

During practically the same hours on Friday there will be another brilliant display, in which the incandescent lights will have no part. On this occasion the powerful arc lamps only will be used, and the novelty of the illumination will be the use of colours. The tints to be employed are red, green, blue, and gold. Each ship will have one colour only, and the colours will be arranged down the lines in the order named—red, green, blue, and gold successively. The unique beauty of this display may be dimly imagined from the directions which are being issued to the ships. From 9.30 to 10.30 p.m. all searchlights are to be trained on the funnels of the ships abreast, in the line on either side, line "B" on "C," etc. During the following hour the ships will train their lights on the funnels of the ships next ahead or astern of them in the line. It is pointed out that "as the lighting of steam is particularly effective with these coloured lights the lights should be kept trained on the funnels, and ships should exhaust into the atmosphere." As the vessels blow off steam, all the various tints will be steadily projected on to the columns of vapour. On the evening of the review the King and the tens of thousands of spectators ashore and afloat will view a combination of these two schemes of illumination. The signal to

Digitized by Google

switch on the incandescent lamps will be the firing of a rocket from the King's yacht, and at 11 o'clock another rocket will be sent up commanding darkness. And the darkness will be all the more intense coming after a display of such brilliance. But alone amid the spectre fleet the Royal yacht will remain illuminated. It is hoped that merchant ships will follow the motions of the fleet in this particular, so that the singularity of the display by the King's ship may be intensified. For 10 minutes darkness will reign, and then the searchlights in all their brilliance will be burnt for 20 minutes, as during the first hour on the previous night. At 11.30 the guns of the fleet will fire a Royal salute, after which the second exhibition of the searchlights will occur. At five minutes before midnight the powerful rays will be directed, at their extreme elevation, upward to the sky, throwing dazzling shafts against the clouds, if there be any. Then, at a signal from the flagship of Admiral Sir Charles Hotham, pitchy darkness will descend on the anchorage, as the electricity is finally switched off. It is impossible to convey any adequate idea of the brilliant and beautiful scene which will be witnessed during this unique display of searchlights and thousands of incandescent lamps. On no former occasion has a fleet been illuminated on such an ambitious and charming plan, which will be rendered all the more impressive by the last boom of the saluting guns, which will signalise the end of the day's memorable ceremonies.

Festivities at the Crystal Palace.—The arrangements made at the Crystal Palace for the Coronation are on a scale of magnificence never before equalled. The stupendous programme, which will extend over several days, includes a grand Coronation ball; a British and American concert in celebration of the proclamation of peace and the Coronation of the King; and Venetian fêtes and firework carnivals, when the unrivalled facilities afforded by the gardens and grounds for illumination and decoration will be fully taken advantage of. These Venetian fêtes will be held on June 26, 27, and 28, and they will be brought to a conclusion each night by a specially gorgeous display of fireworks, when the elaborate set pieces which Messrs. C. T. Brock and Co. have prepared for the Coronation will be fired. For the great Coronation ball to be held on July 2, with the approval of his Majesty the King, and under the presidency of Mrs. Arthur Paget, in aid of King Edward's Hospital Fund, 12,000 square feet of parquet flooring will be laid in the Central Transept, making the largest area ever laid for dancing. Special trains will be run from Victoria to the Palace. The peace celebration of July 5 will be similar in character to that of the patriotic fête held at the Palace on the termination of the Crimean War. The programme will include a performance by the colossal choir of the National Anthem. On this day also the naval and military athletic meeting is to be held. The directors of the Crystal Palace Company have presented a gold cup, to be called the "Coronation Cup," as a trophy for an annual sports competition among his Majesty's forces. The Colonial and Indian troops in London for the Coronation have accepted invitations to be present; and, as on the other nights, a grand display of fireworks will be given. The international polo tournament, held under the auspices of the London Polo Club, for the Coronation Cup, is fixed for July 8, 10, and 12.

TRACTION.

Govan.—A cab driver has been fined 5s. for wilfully obstructing a tramcar.

Heaton Norris.—The Urban District Council have obtained a loan of £7,000 for tramway purposes.

Chester.—At the next meeting of the Tramways Committee tenders for track-laying will be considered.

Bournemouth.—It is hoped to have the electric cars running for traffic on a section of the new electric tramways by July 31 next.

Haslingden.—It is proposed to hold a joint conference of representatives from the three authorities concerned to consider the question of the suggested purchase of the tramways.

Lancaster.—A sub-committee has been appointed to deal with any question arising as to the management of the tramways, and the provision of any materials in connection therewith.

Brentford.—Terms have been arranged between the District Council and the London United Tramways Company as to the proposed line of tramways from Ealing to Brentford.

Spotland.—The Spotland and Norden electric tramways, having been inspected by Major Druitt, of the Board of Trade, on Tuesday, were opened for public traffic on Thursday last week.

Halifax.—The work of constructing the tramway extension from King Cross, Halifax, to Sowerby Bridge, which was begun at the Halifax end about three weeks ago, has now been started at the Sowerby Bridge end.

Rosedale Valley.—The first sod has been cut in the construction of a light railway from Lastingham, through the valley, to Rosedale. The capital of the syndicate which has the powers to carry out the scheme is £75,000.

Scarborough.—The House of Commons had before it on Thursday last week the Scarborough Tramways Bill, for the consideration of the Lords' amendments. No opposition was offered, and the measure was ordered for the third reading.

Morley.—The Light Railway Commissioners have issued an order authorising the construction of the light railways proposed in the borough of Morley and the urban districts of Drighlington, Gildersome, and East and West Ardsley.

Hull.—A number of electric cars are to be decorated for the Coronation. Arrangements are also being made to illuminate the cars at night, a large number of extra incandescent electric lights having been brought into service for this purpose.

Tenterden.—It is reported that the construction of the light railway from Tenterden to Headcorn is shortly to be taken in hand. The line will be in connection with the present light railway to Robertsbridge, and will prove a great boon to that part of the Weald of Kent.

Pontypridd.—A Bill to confirm a provisional order made by the Board of Trade giving to the Urban District Council powers to make certain new tramways within their district is being considered by a Select Committee of the House of Lords presided over by Lord Newton.

Swansea.—The Swansea and district light railways order having now been confirmed by the Board of Trade, the borough surveyor and the electrical engineer are making preparations to commence the works authorised by the order. Plans and specifications are now being got out.

Milan.—A dispatch from this place states that a serious accident occurred there on Saturday on the light railway between Varese and Porto Ceresio. Two electric trains came into violent collision, both being utterly wrecked. The number of persons killed and injured is stated to be 49.

Knottingley.—The Bill to confirm a provisional order authorising the West Riding Tramways Company to make an extension 2¾ miles long from Pontefract to this place has passed the Select Committee of the House of Lords presided over by Lord Newton, and will be reported for third reading.

Bath.—Sir Frederick Bramwell, the arbitrator appointed to name the price to be paid by the Corporation for the tramway company's undertaking, has concluded his enquiry at the Surveyors' Institute, Westminster. The claim of the company, after deductions and agreements, now stands at about £7,500.

Warrington.—The Stockton Heath Parish Council are holding out for the following condition to be observed in the construction of the proposed light railway by the Warrington Corporation to the Market-place, Stockton Heath—viz., that where the Corporation have to acquire property they shall widen the road to 50ft.

Private Bills.—In the House of Lords the Great Northern Railway (No. 1) Bill has been read a third time and passed, and the City and Brixton Railway Bill and the London, Tilbury, and Southend Railway Bill have been read a second time. In the Commons the Great Northern Railway (No. 2) Bill has been read a third time.

Glasgow.—The traffic receipts of the Corporation tramways for the week ending June 14 shows that 3,234,475 passengers were carried over the system, as compared with 3,059,290 on the corresponding week last year, being an increase of 175,185. The money drawn was £11,648. 4s. 1d., against £11,419. 15s. 10d. for the same time last year.

Newcastle.—A collision in which 12 persons were injured occurred here on Sunday night between an electric tramcar and a wagonette filled with passengers. The electric car was travelling in a direction at right angles to the conveyance. The driver of the car was unable to stop it, and the car dashed into the wagonette, cutting it in two parts.

Charing Cross, Euston, and Hampstead Railway.—At a special general meeting of the company held on Wednesday at Hamilton House, Victoria-embankment, a resolution was passed approving an Act for incorporating the Edgware and Hampstead Railway Company, and for empowering them to construct railways, partly underground, from Edgware to Hampstead.

Southend.—On Saturday a boy visitor climbed one of the poles of the electric tramways on the pier, and, unobserved, got on to the track, placing his bare foot on the conductor. He received a shock which caused him to fall on to the conductor and outer rail conveying the return current, and was instantly killed. His body is reported to have been much burned about the thighs and neck.

Cardiff.—Major Druitt, R.E., on Thursday week inspected the remaining section of the new lines for the Corporation electric tramway system—from St. Mary-street, through High-street, Castle-street, and Cowbridge-road, to the junction with Neville-street. This completes the system as originally devised by the Corporation. Most of the horse cars are now taken off, and will be offered for sale at an early date.

Embankment Tramways.—Several petitions praying to be heard in committee on the Bill of the London County Council for the construction of a tramway in a shallow subway from Theobald's-road to the Thames-embankment have been presented, among the petitioners being the Holborn Borough Council, the Great Northern and Strand Railway Company, and the Metropolitan District Railway Company.

Rawmarsh.—The Council have decided to insist upon a clause being inserted in the Mexborough and Swinton Tramway Bill, that the company shall bear the whole of the expenses of the construction and permanent maintenance of the Fitzwilliam Bridge, and also the proportion of construction and maintenance of the Sheffield Navigation Company's bridge, and failing this insertion to oppose the next reading of the Bill.

Huddersfield.—Sanction is to be made to the Board of Trade for authority to construct a tramway in Whitestone-lane, Fartown, and an extension of the line from Crosland Moor terminus to a point in Dry Clough road. The existing tramways with the exception of the Bradley section have now been electrically equipped, and cars are running on them. It is expected that the Bradley section will be finished in about a fortnight.

Staines.—The Council having, for protective purposes, given formal notice of opposition to the new scheme of the London United Tramways, Limited, for the construction of a line along the Bath road to Slough and Datchet, Mr. Godfrey, the company's solicitor, has written asking for an interview before the Council come to a final decision in the matter. The Council have decided to leave the matter in the hands of their solicitor and the surveyor.

Digitized by Google

Salford.—On a proposal at the last meeting of the Town Council that the Tramways Committee should be empowered to accept tenders for materials for the laying of the track in Eccles Old-road, the question was asked why the committee were doing the work themselves instead of letting it out on contract. In answer it was stated that from enquiries made the Tramways Committee were convinced that they could do it as cheaply and make a better job of the work than if they let it out.

Rhondda.—The Tramways Bill, which has already passed a committee of the House of Lords, and the object of which is to authorise the construction of electric tramways in the Rhondda urban district, came before the committee of the House of Commons of which Mr. Tatton Egerton is chairman on Friday. The cost of the scheme is estimated as follows: tramways, £293,000; street widenings, £58,000. The Glamorgan County Council and certain property owners are petttioning against the Bill.

Newport (Mon.).—The Tramways Committee have expressed their disappointment to the Town Council at the action of the Lords Committee in refusing to sanction powers to cross the railway at Pillgwenlly so as to carry the trams to the Alexandra Dock, and brought up for consideration the question whether any steps should be taken with the proposed tramways in Alexandra-road. This tramway, if run from the further side of the Pillgwenlly crossing to the pier head, would have to be worked as a separate section in consequence of the break at the crossing.

Hastings.—The Hastings Tramway Bill, of which the clause relating to the front line has now been struck out in accordance with the finding that the Standing Order requiring proof of the assent of the Corporation had not been complied with, came on as an unopposed Bill before the Earl of Morley last week, for an extension of time till July, 1905, as authorised by the Act of 1900, for the Bexhill and St. Leonards light railway, sanctioned under the Board of Trade order of the same year. Formal proof of the preamble was given, and the Bill was reported for third reading.

Yarmouth.—The electric tramway service was publicly inaugurated on Thursday week in the presence of a large assembly. Previous to the ceremony an inspection took place by the Board of Trade inspectors, Colonel Trotter and Colonel Von Donop, who were accompanied by Major Cardew, the Corporation's consulting engineer, and the Corporation officials. After the ceremony of opening the lines the cars were run for public traffic. The equipment of the new electric tramways includes a telephone line carried from street standards along the route, after the style of the Glasgow tramways.

Leeds.—A Bill to confirm a provisional order made by the Board of Trade authorising the Corporation to construct additional tramways in the borough came last week before a Select Committee presided over by Lord Newton. The London and North-Western Railway Company petitioned against the Bill, the main point at issue between the parties being a proposed tramway over the London and North-Western bridge. In the result the committee decided that they could not sanction any of the points raised by the London and North-Western Railway, and the Bill was passed without amendment.

District Railway.—The Metropolitan District Railway Company, having in view the close relations between the District Railway and the London, Tilbury, and Southend Railway, and the development of the business of the District Railway Company in the East-end of London, have elected as additional director to fill one of the vacancies on their Board Mr. A. L. Stride, who was for many years the manager of the Tilbury Railway, and is now the managing director of that undertaking. The directors have also elected Mr. Charles Spofford, who represents a large financial interest in the company.

Croydon.—The electric tramcars had a field day last Saturday. Owing probably to the comparatively summer weather, the takings on that day amounted to no less than £200 odd. Elaborate preparations have been made by the tramway authorities to celebrate the Coronation in an appropriate manner. A beautifully-decorated car has been got ready, and this is designed to take a chief part in the procession over the entire system of the electric tramways, which has been organised for Thursday evening. On the following day the same car will be available to the public desiring to view the local decorations at special fares.

Central London Railway.—In connection with the note in our last issue under this heading, referring to the contract secured by the British Thomson-Houston Company for 64 motorcar equipments and 160 trailcar equipments, we are now informed by that firm that all the electrical apparatus of the motorcars will be installed in a steel cab separated from the passenger compartments of the motorcar by a fireproof door, thus making the motorcars absolutely fireproof. At the end of last week's paragraph we mentioned that "the trains are now equipped with small chemical fire extinguishers." This, it should be said, in no way applies to the motor equipments themselves, which are such that the possibility of fire is practically nil.

Crystal Palace Light Railway.—The Highways Committee of the London County Council recommend that instructions be given them to take all the necessary measures for opposing the order now being applied for before the Light Railway Commissioners by the Crystal Palace Light Railway and Tramways Company. The company are applying for powers to enable them to construct a light railway from Lordship-lane to the Crystal Palace, but the Highways Committee, while agreeing that it is desirable that further means of access to the Palace should be provided, think that the better course would be for the Council at some future time to seek powers for an extension of the tramway at Lordship-lane to the Palace.

Chatham.—The light railways which were opened last week have been laid down by the Chatham and District Light Railways Company under an order dated August, 1899. The lines, which are in 10 sections, comprise a total length of about 8½ miles. Between five and six miles are laid double, and the remainder single, with passing places. The system unites the two boroughs of Chatham and Gillingham, and brings the suburbs of both towns into communication. The overhead trolley system has been adopted. The electrical equipment was supplied by the British Thomson-Houston Company. Major Pringle, R.E., of the Board of Trade, has recommended that the speeds shall not exceed four and six miles an hour in various streets specified by him, and eight miles an hour elsewhere.

Tube Railways.—A number of Bills authorising the construction of underground electric railways in the Metropolis were read a third time and passed by the House of Lords on Monday after amendments had been inserted providing that at all times the permanent way, rolling-stock, and equipment of the lines should be subject to the approval of the Board of Trade. The Bills passed were the Piccadilly, City and North-East London Railway Bill, the London United Electric Railways Bill, the Great Northern and Strand Railway Bill, the Brompton and Piccadilly (New Lines, etc.) Bill, the Great Northern and City Railway Bill, the Charing Cross, Euston, and Hampstead Railway Bill, and the North-West London Railway Bill. The Baker-street and Waterloo Railway Bill was also read a third time and passed.

Toronto.—A message from Toronto, Canada, states that the street-car men, numbering nearly 1,000, have struck work, with the result that there is a total cessation of the trolley service. The chief points at issue are higher wages and the recognition of the union. The car company have made concessions on the former point, but firmly refuse to do so as regards the latter. A later dispatch, dated June 22, states that the strike of street-car men is now complete. An attempt was made that morning to start the cars as usual with non-unionist carmen. A crowd of sympathasisers with the strikers interfered, however, and in the disturbance which ensued some of the cars were wrecked, while two motormen were severely and several others slightly injured. No further attempt to run the cars was made. A message dated Monday states that the street car strike is now settled, the company agreeing to the men's demands for higher wages and admitting the men's right to organise, while refusing to recognise the union.

Islington.—At the meeting of the Borough Council on Friday the Works Committee recommended (*a*) that they be authorised to arrange, if possible, with the North Metropolitan Tramways Company for the reconstruction by the company of their lines in High-street, Upper-street, Holloway-road, Parkhurst-road, and Camden-road, and the paving with hardwood of the space in between the rails and between the tracks, the Council to pave the margins between the kerb and the outer rail, retaining the granite setts removed from the 18in. margins; (*b*) that the estimates of £29,200, £13,325, and £12,100 submitted by the Finance Committee be approved; and (*c*) that, subject to an agreement being arrived at with the tramways company, application to be made to the London County Council for their sanction to the borrowing of these amounts, and that they be authorised to proceed with the works when such sanction has been received. After a long discussion it was decided to strike out the reference to the Parkhurst and Camden roads and the disposal of the granite setts.

Northfleet.—The chief executive engineer of the British Electric Traction Company has forwarded to the District Council plans and drawings showing the method they propose of carrying their car-shed lighting feeder overhead on the tramway poles along the north side of Pelham and Dover roads from the termination of the Gravesend Corporation's lighting feeder in Pelham-road to a point opposite Cannon-road, and thence along the west side of Cannon-road to the car-shed in Northfleet. The minimum height above the ground level of the cable, which will be a three-core rubber-insulated cable suspended from a $^{7}/_{12}$ steel suspension wire, will be 21ft. 6in., and will be throughout its length on the north side of the road carried on the poles as shown, on the side of the poles remote from the trolley wire. The committee recommend that inasmuch as it appears that the Gravesend and Northfleet Tramways Order, 1899, does not authorise the tramway company to erect posts and wires for electric lighting in the streets of the district, the application be not granted.

Aberdeen.—The Town Council are considering the readjustment of the tram fares, including ½d. stages. It is understood that, in all likelihood, a commencement will soon be made with the construction of a tramway to serve the Ferryhill district. The Corporation have already obtained power to do this, and the feeling is that the most suitable plan would be to form a circular route, branching off Union-street at Crown-street, traversing the latter thoroughfare to its extreme south end, and then proceeding *viâ* Ferryhill-road and Fonthill-road to Holburn-street, where it would join the bridges section of the existing system. Some experimental trials were made on Thursday last week with a car on the electric contact system which has been laid down at the Links. A couple of engineers and several workmen were engaged establishing the connection, and it is stated that the car worked better than it had previously done when trials were made. The car was run along the entire length of the track spanning the Links petween Constitution-street and the beach. It is understood that further trials will be made with the view of perfecting the system.

The Proposed Embankment Tramways.—After passing its second reading in the House of Commons, the clause in the London County Council Subways and Tramways Bill, giving effect to the proposal for an electric tramway on the Thames Embankment, has met with defeat in the House of Lords. It will be recollected that when it was known some weeks ago that the Commons had sanctioned the short length of line referred to, which would have enabled the London County Council to practically join up their southern and northern systems, in conjunction with the authorised subway under the new street from the Strand to Holborn, the action of the Lower House was hailed with delight by the public generally. In spite of popular opinion, however, the Lords have decided that it shall not be. The matter came up for discussion before them on Monday after-

Digitized by Google

noon. It was Lord Newton who moved that it be an instruction to the committee to strike out the clause in question, his chief objection being, as he put it, that the proposal was incomplete, and only meant as a vantage ground from which to make further proposals later on. Lord Newton further contended that it was an unnecessary piece of extravagance, and suggested that the proper means of connecting north and south was by a tubular railway under the river. If their lordships sanctioned this proposal the County Council would seek to extend their tramway system to Piccadilly and Pall-mall, and perhaps would eventually reach the helots of Park-lane. The Lord Chancellor joined in the objection, but it is noteworthy that Lord Morley, who is Chairman of Committees of the House of Lords, opposed the motion. The objectors of the London County Council scheme were, however, too strong, and in the result the motion was carried by the large majority of 77 to 32. This means the extinction of the Embankment tramway so far as the present session is concerned.

London United Tramways.—Since last issue further evidence has been taken by Mr. Compton-Rickett's Committee of the House of Commons on the London United Tramways Bill. Evidence against the Bill was given to the effect that the Barnes tramway would be of no advantage to the inhabitants, and that the proposed embankment would be a source of danger and inconvenience to rowing men. A wall 2½ft. high would sufficiently secure the terrace from flooding. Mr. C. J. Owens, general manager for the London and South-Western Railway, gave evidence in support of the petition of that company in opposition to the Bill. Between the stations at Kew Bridge, Brentford, Isleworth, and Hounslow there had been a reduction in gross receipts from £1,516 to £524 in the half-year since the completion of the tramways. He had reason to fear that the present proposals, if sanctioned, would have an equally injurious effect on the traffic of the company, and it had not been found that the action of tramways as feeders to railway stations had any compensating advantage. An agreement was about to be concluded between his directors and the District and Metropolitan Companies for the electrification of the London and South-Western line between Richmond and Hammersmith and other parts of the London and South-Western Railway over which the other companies had running powers. The proposed line from Wimbledon to Malden would amount to a duplication of the route of the railway. On the railway between Wimbledon and Raynes Park to stations on the route of competition, 838,819 passengers were carried in 1901, the receipts were £9,479, and the average was 2¾d. per passenger. A reduction of that traffic in proportion to past experience would mean a loss of £6,066. In reference to the competition of the Tooting extension, he mentioned that his company were spending £1,700,000 on improvements between Clapham Junction and Waterloo to give improved service to the whole of the suburbs. A railway company constructed their line on land they had purchased at great expense, while a tramway company had free use of a public road and the public lighting, which was paid for out of the rates. The need of accommodation for the working class at Richmond did not justify this competition by tramway. The railway company carried a passenger 19½ miles on a 6d. return ticket, and in 1901 the London and South-Western Company issued 103,364 tickets by six workmen's trains, starting at 7.48 in the morning. Obligation rested on railway companies under the Cheap Trains Act to provide facilities for working-class travelling, and the London and South-Western Company issued working-class tickets to all applicants. There was very small demand for such tickets on the line between Richmond and Hammersmith, the average being seven by one train and six by another on the District Railway. On Friday the committee passed the preamble of the Bill, authorising practically all the extensions proposed by the company. The new lines will link up Malden and Wimbledon with the London County Council tramways in South London, the committee only deleting a portion of the spur lines to the common. They also passed the whole of the Richmond, Mortlake, and Barnes extensions, with the exception of the piece across Hammersmith Bridge, in respect of which they accepted the assurance of the London County Council that they would construct the tramway over the bridge so as to afford the continuous route into Hammersmith.

London County Council Tramways.—A long report of great interest to those in the tramway world was presented to the London County Council at their meeting on Tuesday by the Highways Committee. Dealing first with the southern system, purchased from the London Tramways Company, the report states that the net capital expenditure upon this undertaking up to March 31 last was £896,971. The total receipts from the undertaking during the year amounted to £462,133, while the working expenses were £409,623, showing a profit on working of £52,510. Out of this balance debt charges have had to be met *a*) for interest, £22,182; and (*b*) for sinking fund, £21,265—a total of £43,448, leaving a balance of £9,062 to be carried to the appropriation account. The Council has established in connection with the undertaking a renewals reserve fund, to which the sum of £9,000 has been paid out of the revenue of the year. The balance to the credit of this fund on March 31 last was £23,583, of which £12,015 was invested in 3 per cent. London County Council consolidated stock. The Council has introduced various improvements in the system as compared with the company which formerly owned it. It has established a 10 hours' day—a 60 hours' working week—for all classes of its tramway employés, readjusted the rates of pay, provided uniforms for drivers and conductors, and improved the conditions of labour of certain employés, the total concessions involving an extra payment of £24,000 during the year. The Council has also established all-night car services at workmen's fares on four routes, and revised the fares throughout. These concessions have, the committee state, been much appreciated, as will be seen by the fact that the number of journeys run by cars carrying passengers at workmen's fares had up to March 31, 1901, increased by 36 per cent., and that during the year ended March last no less than 2,465,389 two-journey tickets and 1,972,223 exchange tickets, or a total of 4,457,612 tickets, had been issued. The number of passengers carried during the year was 119,880,555, the average fare per passenger was ·88d., and the number of miles run by cars and omnibuses was 10,371,866. The committee also submitted the accounts of the northern system, which is leased to the North Metropolitan Tramway Company. The total capital expenditure in respect of the undertaking is £848,884. The receipts for the year 1901-2 from the North Metropolitan Tramway Company, the Council's lessee, by way of rent of the lines, depôts, buildings, etc., have amounted to £55,788, the percentage on excess of the gross receipts of the company over those of 1895 amounts to £18,697, and percentage on extensions to £2,355, so that the total rents received from the company were £76,841, while rents amounting to £284 were received from tenants of properties belonging to the Council in Parkhurst-road. Thus the total receipts from all sources in respect of the undertaking have amounted to £77,125. The charge for interest on debt, less income tax, was £22,486, and for sinking fund £14,905, while ground rent, insurance, repairs to premises, and other incidentals have amounted to £577, making the total expenditure £37,969. The balance of receipts over expenditure is, therefore, £39,156. The total surplus from tramways applicable to the relief of the rates is £45,181, and the committee propose to transfer £45,000, leaving a balance of £181 to be carried forward to next year. This will be done as soon as the cash balance of the tramway account admits of it being done. The committee will shortly recommend the London County Council to advertise for tenders for electrical cars of a special kind for use on the Streatham line. The bodies of the cars will be carried on single trucks, and not on bogies, as are those on the Tooting lines. The reason for single-truck cars being preferred instead of bogie cars is that the gradient of Streatham-hill is steep, and experience has shown that the maximum traction trucks have given considerable trouble on heavy gradients, as the driving wheels have a tendency to slip in mounting a hill. Moreover, the weight of a single-truck car is about two tons less than that of a bogie car, and, as these cars will at first have to be pulled by the cable, the difference in weight is of considerable importance. The cost of these cars is estimated at £53,000. Notices were served in October last upon the South London Tramways Company requiring it to sell to the Council the portions of the company's undertaking authorised in 1879 and 1880 respectively, and the Council further decided to give notice after Aug. 11 of this year in respect of the portion of the undertaking authorised in 1881. Since the service upon the company of the notices referred to, negotiations have been proceeding for the acquisition by the Council of the whole of the company's undertaking, with the result that the directors of the company have stated that they are prepared to recommend the shareholders to accept the sum of £198,500 for the lines and depôts, including goodwill, in respect of the parts of the undertaking not yet purchasable under Section 43, and £2,650 as compensation to directors and officials, making a total of £201,150. In the opinion of the Highways Committee the offer is fair and reasonable to both the Council and the company, and they think it somewhat doubtful, judging by recent cases of the purchase of tramways by other authorities, whether more favourable terms would have been obtained by the Council if the matter had gone to arbitration. Legal and other expenses of the transfer will, the committee think, amount to about £3,000. It is proposed that, if possible, the transfer shall take place on Nov. 1 next. The Council will also have to purchase the rolling-stock, horses, consumable stores, etc., at a price, failing agreement between the Council and the company, to be settled by an arbitrator to be mutually agreed upon. These proposals of the committee will be discussed on July 8. At the same time proposals of the Highways Committee to construct over 33 miles of new tramways at an estimated cost of £1,738,857 will be considered. There will be 11½ miles of lines on the north of the Thames, which are estimated to cost, with the cars and car-sheds, £529,850, and for street widenings £54,416. On the south side the mileage of new lines amounts to 22, and the cost of construction and plant is estimated at £945,700, and street widenings at £198,891. The committee propose that the new lines which will be ultimately connected with the North Tramways Company's lines, leased until 1910, shall be constructed for horse traction, unless before the time arrives for their construction, effect shall have been given to the provisions in the company's lease relating to the reconstruction for electric traction of the leased tramways or the parts of them immediately adjacent to, and to be worked in connection with, the new tramways. Those of the new lines which will be ultimately connected with the London County Council tramways, on which, being at first detached from either of the Council's tramway undertakings, could be worked independently, they propose shall be constructed for electric traction. The following are the routes of the new lines proposed: (1) Hampstead-road tramways terminus to a point in Tottenham Court-road near Oxford-street; (2) Edgware-road to Harrow-road, *viâ* Sutherland-avenue; (3) Harlesden to Hammersmith-broadway; (4) Shepherd's Bush-road to a point near the Marble Arch; (5) Marble Arch to Cricklewood; (6) Greenwich to East India Dock-road, *viâ* the Blackwall Tunnel; (7) Westminster Bridge-road to the Victoria-embankment; (8) Deptford to the Herbert Hospital, Woolwich; (9) New Cross to the South-Eastern Metropolitan Tramways; (10) Clapham Common to the county boundary in Kingston-lane; (11) Battersea Park-road to Chelsea Bridge, *viâ* Battersea Bridge; (12) Tooting-broadway to Tooting Junction Station; (13 Rushey Green to Bromley Hill; (14) Rushey Green to Crystal Palace; (15) terminus of Woolwich and South-East London Tramways to the county boundary *viâ* Wickham-lane. The purchase of the site of the Pimlico gasworks for the erection of a generating station for the western tramways has been completed. Tenders received at the last meeting of the Council for the erection of an engine-house at Loughborough Junction for the Council's tramways have been referred to the Highways Committee to report upon.

Digitized by Google

Sheffield.—The Walkley Ward Liberal Association have passed a resolution strongly deprecating the constant overcrowding of the Walkley tramcars, and the proposal of the Tramways Committee to reduce the present service to the terminus, and urging it to provide more cars in the morning, noon, and especially in the evening hours.

Bolton.—The report of Mr. Arthur A. Day, electrical engineer, on the tramways for the year ending March 31 last states that during the year all the cars, except four, have been rewheeled with steel-tyred wheels with wrought-iron centres, a change which has been an unqualified success. The real cost of repairs to cars came out at about 1·02 per car, not an excessive amount considering the condition of the track. The report of Mr. Morgan, the borough surveyor, gives details as to the relaying of the track, the total length of lines relaid and doubled being 12 miles 685 lineal yards of single line. The committee, after visiting Bradford, and seeing the tramways laid there on the Demerbe system, decided that the route from Park-street to Princess-road should be laid on that system, and contracts were entered into with the patentees, and the excavating, cementing and paving with Mr. Robert Heaton. The works, so far as they have been completed, are satisfactory, but the progress has been exceedingly slow, this being largely attributed to the hard winter and to the adoption of an entirely new system of laying. The one feature of the system is the joint, but Mr. Morgan does not consider that the Demerbe is superior to the girder system as at present constituted. The total cost of the girder lines laid during the past year has been £38,593, and the length equals 9 miles 1,483 yards of single track, the average cost per mile of straight track being £3,920. The estimated cost of the work as per the parliamentary estimates was £49,600, or £5,038 per mile of single track, the actual cost being upwards of 22 per cent. less than the estimate. The work proposed for the coming year consists of the relaying of the lines to Farnworth, and doubling the Daubhill section; the construction of the lines from Hulton-lane to Four Lane Ends, to join the South Lancashire tramways; and the construction of the lines from Tootill Bridge to the borough boundary at Ainsworth Bridge, the estimated cost of works being £41,902. The traffic manager reports a satisfactory increase in the receipts. The figures show that the receipts (£77,274. 17s. 5d.) over 1901 give an increase of £8,127. 16s. 3d., and the passengers carried in 1901-2 were 15,828,933. The total traffic expenses amounted to £22,838. 5s. 8d. The repairs and maintenance of electrical equipment cost £1,164. 1s. 3d., and the repairs and maintenance to permanent way £3,235. 11s. 1d. The repairs and maintenance to rolling-stock cost £9,437. 18s. 8d.

TUNBRIDGE WELLS ELECTRICITY ACCOUNTS.

From the accounts of the Tunbridge Wells electricity works for the year ended March 31, 1902, it appears that the total expenditure on capital account to date amounts to £65,934. Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc., are appended:

BELFAST ELECTRICITY ACCOUNTS.

The accounts of the Belfast electricity works for the year ended March 31, 1902, state that the total expenditure on capital account was £204,357 Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc., are appended:

REVENUE ACCOUNT.

Dr. Generation.	£	s.	d.	£	s.	d.
Fuel	£3,055	8	10

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T. units		889,027
Quantity sold: Public lamps	446,011	806,280
Quantity sold: Private consumers by meter	360,269	
Quantity used on works		21,820
Total quantity accounted for		828,100
Quantity not accounted for		60,927
Total maximum supply demanded (kilowatts)		510

Number of public lamps, 1,025, equivalent to 4,100 8-c.p. lamps.

KING'S LYNN ELECTRICITY WORKS.

The following statement shows the receipts and expenditure for the year ended March 31, 1902, in connection with the Corporation electricity undertaking. The total expenditure on capital account to date amounts to £44,460 :

Expenditure.	£	s.	d.
Coal	703	11	0
Oil, waste, etc.	113	0	1
Wages	521	6	5
Repairs	170	19	5
Works cost	1,508	16	11
Rents, rates, etc.	170	14	10
Management, etc.	408	6	7
Total works cost	2,087	18	4
Street lamps	248	2	5
Interest	1,119	6	3
Sinking fund	1,310	0	0
Total cost per unit, 3·988d.	£4,765	7	0

Income.	£	s.	d.
Private consumers	1,837	8	5
Public lighting	1,663	15	11
Street lamps	248	2	5
Meter rents	99	3	5
Profit on fittings	123	11	3
Total	£3,972	1	5
Deficit	£793	5	7

BARNES ELECTRICITY ACCOUNTS.

From the accounts of the Barnes electricity works for the year ended March 31, 1902, it appears that the total expenditure on capital account to date amounts to £31,112. Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc., are appended :

REVENUE ACCOUNT.

Dr. Generation of Electricity.	£	s.	d.
Coal or other fuel	248	9	5
Oil, waste, water, and stores	18	13	10

PROVISIONAL PATENTS, 1902.

JUNE 13.

13438. Improvements in electric railway systems. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Thomas Edward Murray and John van Vleck, United States.) (Complete specification.)

JUNE 14.

13491. Intercommunication switch for telephones. Harry Riley Webb, 55, Holgate-road, Nottingham.

13500. An improved apparatus for commuting electric current particularly applicable to combined arc and incandescent electrical lamp circuits. C. E. and H. M. Peel, Limited, Upper Strand, Swansea.

13517. Improvements in continuous-current generators or motors with open winding. Ellis Carl Artur Andreen and Otto Stalhane, 18, Southampton-buildings, Chancery-lane, London.

13526. Improvements in means for electrically operating countershafts. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Norman C. Bassett, United States.)

13527. Improvements in electrical measuring instruments. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Lewis T. Robinson, United States.)

13528. Improvements in inertia dampers for electric measuring instruments. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (William H. Pratt, United States.)

13529. Improvements in electric starting rheostats. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles E. Harthan, United States.)

13530. Improvements in brush-holders for dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Norman C. Bassett, United States.)

13531. Improvements in electric snap switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Henry Geisenhoner, United States.)

13532. Improvements in connection with electric condensers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Walter S. Moody, United States.)

13533. Improvements in armature bands for dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (James J. Wood, United States.)

13534. Improvements in electrical motor control systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles E. Barry, United States.)

13539. Improvements in electric wires. William Herbert Hyatt, 77, Woodstock-road, Bedford-park, Chiswick, London.

13556. Improvements in means for the control of the supply of electricity to electric motors for hauling plant and similar apparatus in which the demand for energy is intermittent. Carl Ilgner, 1, Queen Victoria-street, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published July 3.

1901.

15216. Electrically-propelled vehicles and permanent way therefor. Burnaby.

15769. Manufacture of incandescing electric lamps. Voelker.

17320. Electrolytic manufacture of chlorates, perchlorates, bromates, iodates, and the like. Corbin. (Date applied for under International Convention, March 25, 1901.)

19748. Electric meters. Loubery and Baudrey.

25433. Speed-regulating device for overhead electric carriers. Harding.

1902.

4372. Electrical warp and weft controlling mechanisms for looms. Kip.

7661. Electrolytic refining and depositing of lead. Betts.

8670. Electric arc lamps. Carbone.

9178. Magnetic compasses. Lilley.
